Bradshaw Lecture

ON

THE SURGERY OF THE HEART.

Delivered before the Royal College of Surgeons of England on Dec. 11th, 1919,

BY SIR CHARLES BALLANCE, K.C.M.G., C.B., M.V.O., M.S. LOND., F.R.C.S. ENG.,
CONSULTING SURGEON TO ST. THOMAS'S HOSPITAL, ETC.

MR. PRESIDENT AND GENTLEMEN,—It is my first duty and pleasure to acknowledge the honour conferred upon me by my colleagues in selecting me to deliver this lecture, the very title of which is evidence of the marvellous progress which the science and art of surgery has made during my lifetime. When I became a Member of this College the surgery of the heart did not exist. No surgeon had operated on the heart itself, though a few attempts to evacuate pericardial effusions had been recorded. A wound of the heart was considered by the ancients as surely fatal and this opinion was endorsed by the faculty. It has been pointed out, however, that "the great dramatic poets did not seem to attach a definite fatality to wounds of the heart, for they made their suicides kill themselves in other ways."[1]

HEART WOUNDS IN THE CLASSICS.

Suicides in tragedy sometimes hang themselves, but Ajax falls on his sword (he was always a feckless fellow). The narrative[2] is not quite clear, as his wife, who tells it, is naturally scared, and seems to have confused a sword with a spear; but he died at once with such a gush of blood at the nose that she covered him up with a cloak, for fear anyone else should see him; there was hæmorrhage from the wound too. His brother, Teukros, later on, says it was a sword, and he ought to know!

Ovid[3] writes: "Sanabit nulla vulnera cordis ope," and, unlike most of his references to the human heart, which deal with breakages rather than repairs, this line really refers to medical treatment, or rather to the impossibility of doing anything in a remedial way to heart wounds.

Celsus,[4] a contemporary of Ovid, gives the signs of a lingering death: "The heart being wounded, blood escapes in abundance, the pulse vanishes, there is extensive pallor, there occur cold and malodorous drops of sweat all over the body, the extremities become cold and death follows."

The special sign, that of movement of the weapon with the heart beat, was noted by Homer:[5] "And the hero, Idomeneus, smote him (Alkathous) in the midst of the breast with the spear. And he fell with a crash, with the lance fixed in his heart that, still beating, shook the butt-end of the spear."

"He fell, the spear point quivering in his heart,
Which, with convulsive throbbing, shook the shaft."[6]

The sudden death following the withdrawal of the penetrating weapon occurred to Epaminondas at the battle of Mantinea (B.C. 363):—

"At last, while he was most heroically exerting himself to gain the victory for his country he received a mortal wound in his breast by a dart thrown with such force that the wood broke and the iron remained in his body and he fell to the ground. And Epaminondas, yet living, was brought to the camp; and when the physicians who were sent for told him that he would certainly die as soon as the dart was drawn out of his body, he was not at all daunted; but first calling his armour-bearer he asked whether his shield was safe. The armour-bearer said it was and showed it to him. Then he enquired which side had won the day. The youth made answer that the Bœotians were the victors. 'Why, then,' said he, 'now is the time to die,' and forthwith ordered the dart to be drawn out, and so upon the drawing out of the head of the dart he quietly breathed his last."[7]

Again, Homer[8] narrates the story of the wounding of Sarpedon by Patroklos with a javelin "where the midriff clasps the beating heart." Sarpedon fell as falls an oak—"and from him Patroklos drew out his spear point and the life together." Sarpedon, addressing his friends when wounded, said:—

"Defend my body, conquer in my right
That taught by great examples, all may try
Like thee to vanquish, or like me to die."

He ceased—

"The insulting victor with disdain bestrode
The prostrate prince, and on his bosom trod;
Then drew the weapon from his fainting heart,
The reeking fibres clinging to the dart.
From the wide wound gushed out a stream of blood;
And the soul issued in the purple flood."

Nowadays we should take measures by exposure of the heart, &c., to prevent hæmorrhage when the missile or weapon was withdrawn, though it does not seem very long ago that the withdrawal of a file from the Austrian Empress's heart ended in sudden death (September, 1898).

HEART WOUNDS IN EARLY MEDICAL LITERATURE.

Riolanus[9] (1649) less than 300 years ago opens his chapter on the heart with these words:—

"The heart is the chief and most noble organ in the body. It is the source of that life-giving nectar by the influx of which the vitality of each part of the body is renewed and cherished. The organ which is the first to be born and the last to die, and through which all other parts of the body live and move and have their being."

Other authors of this period use much the same language. Ambrose Paré[10] (1691) writes:—

"The heart is the chief mansion of the soul, the organ of the vital faculty, the beginning of life, the fountain of the vital spirits, and so consequently the continual nourisher of the vital heat, the first to live and the last to die."

Paul Barbette[11] (1687), of Amsterdam, a contemporary of Ambrose Paré, writes as follows:—

"Wounds of the heart are always mortal and those that penetrate into the left ventricle kill suddenly. Those so wounded seldom live above 6, 12, or 20 hours, although there are examples produced to the contrary. A wound in the right ventricle permits the patient to live longer, and one which terminates in the substance of the heart grants yet longer time."

Cabriolanus[12] (1604) mentions a case in which he found a scar and another in which he found an unhealed wound in the heart. He agrees with Fernelius that the heart can suffer a solution of continuity without death ensuing; and, he adds, lest anyone should think that these heart lesions were the cause of death, that both those persons were hanged.

Tourby,[13] in 1642, did an autopsy on a man who, four years previously, had had a sword-thrust in the chest which caused a wound of the heart near the apex; the evidence of which was a cicatrix that could be demonstrated to all present.

In the succeeding centuries there is little to note till the time of Bonetus[14] and Morgagni.[15] They established two facts: (1) That wounds of the heart were not necessarily immediately fatal; (2) that a sudden effusion of blood into the pericardium arrested the heart's action.

Bonetus relates the case of a young man, aged 24, who bravely sustained an attack by seven others, but was at length wounded by a sword-thrust. He survived five days. There was a wound of the left lung and of the right ventricle of the heart.

Morgagni compares two cases of heart wound. In one there was a free opening in the pericardium and the blood escaped freely externally. This case lived eight days. In the other the blood was retained in the pericardium and the patient died in a few minutes. He points out that the second case did not die from hæmorrhage, but from pressure on the heart. Thus, a hæmorrhage within the pericardium is much more quickly fatal than a hæmorrhage in most other places, even though it be far less in amount.

Interesting cases of heart injury abound in literature. A few may be quoted:—

1. Ambrose Paré thus describes a case: "When I was in Turin I saw a certain gentleman who in a duel received a wound under his left breast which pierced into the substance of the heart; yet for all that he struck some blows afterwards, and followed his flying enemy some 200 paces, when he fell down dead upon the ground. Having opened the body I found a wound in the substance of the heart so large as would contain one's finger. There was much blood poured forth upon the midriff." (Query: Did the gentleman die of auricular compression?)

2. A pointed piece of stick was found in a pig's heart. The swineherd stated than more than six months previously he had prodded the unruly animal with the stick he used for driving his pigs.[16]

3. A boy in 1834 lived five weeks and two days after a gunpowder explosion, which blew a piece of wood into his chest. At the post mortem a piece of wood 3 inches long and as thick as a cedar pencil was found in the right ventricle.[17]

4. A man, aged 50 years, died in hospital in 1825. Nine years previously he was wounded by a knife thrust into the left side of the chest. The edges of the pericardial wound were adherent to the chest wall and a firm fibrous cicatrix was found going through the whole thickness of the right ventricle in a line corresponding to the wound of the pericardium.[18]

5. In 1827 a medical student in Paris was stabbed in the left chest. (He came under the care of Dupuytren.) A jet of blood, as large as a pea, and air came from the wound. The flow of blood increased when the patient groaned. He recovered in 28 days. The treatment was mainly by bleeding.[19]

Dupuytren's advice in these and similar cases was to go on bleeding as often as the pulse revived and only to leave sufficient blood to keep the patient alive. This recommendation reminds one of Dr. Sangrado in "Gil Blas." He believed that it was a mere vulgar error that the blood was of any use to the system—according to him, the faster you draw it off the better. Sangrado despatched business so fast that the fraternity of notaries who made wills in Valladolid in his time found half their jobs spoiled as they could not keep pace with him. The difference between the great French surgeon and the charlatan Sangrado is obvious. Depuytren's case recovered, but no patient of Sangrado's was ever known to do so! For "Mere prattle ...... was all his soldiership."[20]

We may conclude, then, that in wounds of the heart a free external hæmorrhage is less dangerous than a sudden filling of the pericardium with blood. Wounds of the heart, too, under some circumstances do not allow the continued escape of blood. They close and heal as do certain wounds of the great arteries.

Mr. Mansell Moullin showed a case at the Clinical Society in 1897.[21] The man had received a severe blow from the point of an elbow on the third left costal space in a football match. Twenty-five days later, when the patient was in extremis, the pericardium was opened in the left fifth costal space, and a drainage-tube was inserted. In three hours six pints of thin dark fluid escaped through the drainage-tube. This case was one of rupture of the heart without external wound, and slow accumulation of blood in the pericardial cavity occurred. In the same volume of the Clinical Society's Transactions a case of punctured wound of the right ventricle is narrated by Mr. W. G. Spencer.[22] There was considerable external hæmorrhage on the eighth and seventeenth days. Death occurred on the seventy-ninth day. There was a healed wound of the wall of the right ventricle, which was adherent to the scar in the pericardium.

ATTITUDE OF NINETEENTH CENTURY DOCTORS ON HEART SURGERY.

Remarks of well-known surgeons and physicians of the nineteenth century showing that surgery of the heart itself was considered a hopeless matter down to quite recent years.

Guthrie[23] writes:—

> "London, the great metropolis of the British Empire, with its 2,000,000 of inhabitants has been nearly exempt from injuries of the heart. There is not at the present moment a surgeon of any of its largest hospitals who has seen or recollects a case of recovery after a wound of the heart, either in his own practice or in that of his colleagues or predecessors. They have rarely seen a case brought to them alive for treatment, sensible people not being disposed to stab each other, while madmen try to kill themselves in a different way."

Sir Thomas Watson[24] writes:—

> "If the patient is in danger of perishing from the amount of the pericardial effusion the *ultimum remedium* of tapping the distended bag must be adopted. The puncture should be made with a fine trocar after a preliminary incision of the skin through the inner end of the fourth left intercostal space. I have never seen this done nor met with any case in which it appeared to be demanded; but it has been done with great present relief to the patient."

Billroth,[25] who was certainly not a timid surgeon, wrote (circa 1875):—

> "Paracentesis of the pericardium is an operation which, in my opinion, approaches very closely to that kind of intervention which some surgeons would term a prostitution of the surgical art and others madness. It is only to remove from this section the reproach of being incomplete that we mention this operation, which has more interest for anatomists than for surgeons. Perhaps a later generation will think otherwise about it. Treatment is becoming more and more surgical, and those most deeply concerned in the practice of internal medicine make plans for the boldest operations."

Legouest[26] says:—

> "It might be thought that nothing would be of greater interest than the study of wounds of the heart, but, in fact, there is nothing of less practical interest. A few curious but authentic facts, others more or less doubtful, an uncertain symptomatology, a treatment all but hopeless, an ending almost always fatal, such is a summary of the impression resulting from a study of wounds of the heart."

Riedinger[27] in 1888 wrote:—

> "The suggestion to suture a wound of the heart, though made in all seriousness, scarcely deserves mention."

From the time of Morgagni onwards clinical and pathological observations and records became more accurate, and the symptoms and lesions of injuries and diseases of the heart gradually became better known.

The paper published by Fischer[28] in 1868 marks the close of this period. It is an admirable clinical and pathological record, but lacks any serious suggestions for surgical treatment.

While the opinion prevailed that arrest of the function of the heart would follow surgical interference with this organ, and so long as the ancient reverence attaching to the tissues of the heart prevented lesions of the heart being treated on ordinary surgical principles, it was natural that no one suggested that wounds of this organ should be sutured.

It is scarcely 20 years ago that surgical measures found a definite place in the treatment of injuries and diseases of the heart.

WOUNDS AND DISEASES OF THE HEART.

Besides wounds inflicted by cutting instruments and bullets, and traumatic ruptures of the heart, the heart may be the site of aneurysm from disease. There are several such cases recorded in literature.[29] Traumatic aneurysm is the cause of secondary hæmorrhage in wounds of the heart as it is in wounds of the great arteries, especially in cases of pericardial sepsis. Cases of suture of the heart that are apparently doing well for many days or longer, and then die of secondary hæmorrhage into the pericardium, are cases of rupture of traumatic aneurysm of the heart.

Case of Cardiac Aneurysm.[30] A man had been wounded 10 years before his death by a knife-thrust to the left of the sternum. A cardiac murmur had been audible since the injury. He gradually recovered from the wound and felt no inconvenience until a few weeks before his death.

Autopsy: Heart enlarged, universal pericardial adhesions. Through the pericardium a hard, prominent substance could be felt in the wall of the right ventricle. The pericardial adhesions could be separated everywhere but over this swelling. The hypertrophy of the heart affected chiefly the left ventricle, the cavity of which was elongated and expanded. On the inner aspect of the wall of the right ventricle was an opening through which the little finger could be passed into a cavity as large as a walnut, at the bottom of which was felt a hard nodular body. The sac proved to be an aneurysm of the heart, the wall of which was entirely formed by the fused layers of the pericardium and contained no muscular fibres. In the sac was a hard fibrinous clot. Opposite the opening of the aneurysm into the right ventricle was an opening in the septum leading into the left ventricle.

A wound of the trunk from a bayonet or lance is not often seen in hospital. The reason is that such wounds are so serious that the soldier seldom survives. Guthrie[31] gives another reason for these wounds being uncommon. After describing bayonet and lance wounds, he continues:—

> "Opposing regiments, when formed in line, and charging with fixed bayonets never meet, and struggle hand to hand, foot to foot, and this for the very best possible reason that one side turns round and runs away as soon as the other comes close enough to do mischief, doubtless considering that discretion is the better part of valour. Wounds from bayonets were rare in the Peninsular War. It may be, that all those who were bayonetted were killed, yet their bodies were seldom found. Small parties of men may have personal conflicts after an affair has been decided; or in the subsequent scuffle if they cannot get out of the way fast enough. The battle of Maida is usually referred to as a remarkable instance of a bayonet fight; nevertheless, the sufferers, whether killed or wounded, French or English, suffered from bullets, not bayonets."

EXPERIMENTS ON THE HEART OF ANIMALS.

The most important observation was made by Morgagni in his De Sedibus et Causis Morborum that a puncture of a coronary artery on the external surface of the heart might cause such an amount of hæmorrhage into the pericardium as to compress and arrest the heart. This was the first indication that surgical exposure of the pericardium and the evacuation of the fluid within it might relieve the heart from compression.

There have been many surgeons during the last 150 years (including Baron Larrey,[32] Napoleon's surgeon) who have endeavoured by experiments on dogs to discover why wounds of the heart were fatal and how death could be prevented.

Between 1882 and 1895 the surgeon experimenters discovered (1) that blood effused into the pericardium must be removed because it embarrassed the action of the heart, and (2) that a wound into the cavity of the ventricle of the dog's heart could be successfully sutured.

The first successful experiment of making a wound in the heart of an animal and then closing the wound by suture was performed by Del Vecchio[33] in 1895 and he suggested the method that should be adopted in operations on man.

Remarks from Del Vecchio's paper. As a result of experiments on dogs he concludes that suture of the heart of man in cases of wound is possible. At the Congress of Rome (1894) he showed a dog in which a penetrating wound of the ventricle had been sutured successfully with catgut. The dog was killed on the fourth day. There is a special difficulty in dogs as the pleura must be opened. He proposes removal of the fourth, fifth, and sixth rib cartilages in man. The pleura is to be pushed on one side, then the pericardium incised, blood and blood clots removed, and the wound in the heart sutured. Death may be caused by the pressure of the blood in the pericardium, but this pressure also checks the bleeding which is liable to recur fiercely as the intra-pericardial pressure disappears.

These experiments were confirmed by Salomoni of Messina,[34] who also experimented on dogs. A wound was made in the left ventricle and then sutured, and the dogs when killed after healing had taken place, presented only a pericardial adhesion at the site of injury. These successful experiments stimulated surgeons to attempt suture of the heart in man. Farina,[35] Cappelen,[36] and Rehn [37] were first in this operative field. Thus commenced a new and wonderful advance in surgical practice.

In dogs the different great vessels can be compressed during operation, keeping the heart empty and the operation bloodless. "The same expedient might be employed in man."[38] The pulling forward of the apex of the heart by a fixation stitch will, to some extent in man, kink the great vessels and so effect the same purpose.

Rehn has proved experimentally that the most effective way to obtain hæmostasis in heart suture is by grasping the root of the heart on a level with the right auricle and compressing the vena cavæ at their entrance into the auricle.

The late Sir Lauder Brunton[39] published a preliminary note on the possibility of treating mitral stenosis by surgical methods. He suggested that a mitral stenosis could be transformed by a surgical operation with benefit to the patient into one of mitral insufficiency or regurgitation. Cushing and Branch[40] reported some experiments on this question. Bernheim[41] in 1909 established experimentally a condition of mitral stenosis in dogs by means of inserting sutures. He later relieved this artificially-produced stenosis in the animal by establishing at a second operation a condition of mitral insufficiency. As superior to drainage, he left a small gap in the pericardium unclosed for the escape of exudation.

"Not only can lesions of individual valves be produced without immediately fatal consequences to the animal, but the survival of the animal is sufficient to permit a careful study of the primary and secondary disturbances of the circulation which closely imitate the same phenomena caused by cardiac disease in man. Obstructive and regurgitant lesions of the aortic pulmonary mitral and tricuspid valves and septal lesions imitating congenital deficiencies can now be systematically produced in the laboratory."

"Though the surgeon may not be able to profit immediately by these brilliant laboratory accomplishments in cardio-valvular surgery, they show that with proper methods and with a comparatively simple technique successful intracardiac surgery in man is possible."[42]

For the present it is sufficient to affirm the obvious fact that without the successful experiments on the suture of a wound of the dog's heart the suture of a wound of the heart of man would never have been an accomplished fact.

Farina's case. Farina sutured a wound in the left ventricle of a man, and the patient lived several days.

Private Letter to Sir John Bland-Sutton from Dr. Guido Farina, December, 1909.

"The first case of surgical interference on the heart which I had the opportunity of performing was carried out in March, 1896, at the Spedala della Consolazione. The patient was a man 30 years of age, who received a blow from a very fine and sharp dagger in the fifth intercostal space in the parasternal line. The wound penetrated to the cavity in an oblique direction from above downwards and from without inwards. It wounded the pericardium and penetrated into the ventricle. The wound in the myocardium was about 7 mm. long. I removed the fifth costal cartilage and a bit of the rib for about 15 cm. Then I strongly retracted the fourth and sixth costal cartilages. I arrived on the wounded heart. I sutured the wound with three silk sutures, and between these particular points I placed two others of less importance. Everything went well till the fifth day, when a violent broncho-pneumonia declared itself on the right side and in three days killed the patient. The thoracic wound healed by primary intention.

At the autopsy the wound in the heart was found perfectly healed. The heart was not allowed to be preserved for further study. It was precisely because of my irritation at this fact that I have not published any communication on this interesting case."

Cappelen's case.

A man, aged 24, received a stab wound in the left side some hours before admission. He went home alone, and about an hour afterwards was found lying in a pool of blood. On admission he was unconscious, but the heart sounds could be heard though he was pulseless. A punctured wound was present in the fourth left interspace in the mid-axillary line. He improved with a camphor injection.

Operation.—Wound enlarged, fourth rib resected. Pleural cavity filled with blood, 1400 c.cm. The lung was not wounded; 5 cm. of the third rib then resected. Wound of pericardium, 1 cm., was then seen; this was enlarged, and the blood and clot in pericardium removed. The wound in the pericardium being enlarged and the blood and clots in the sac removed, a wound 2 cm. long was seen in left ventricle. The wound was sutured and a bleeding artery on the heart tied. Patient lived 2½ days. Septic pericarditis was present.

Rehn's case.

The patient was exhibited 14 days after the operation. The man had been stabbed with a table knife; and there was bleeding from the wound, and signs and symptoms of distension of the pericardium. On the day following the injury, Rehn removed the blood clot from the pericardium as well as from the left pleural cavity. He also inserted sutures into the wound in the wall of the heart, and afterwards closed the opening in the pericardium and chest wall except for drainage. On the fourteenth day the patient was recovering well.

Treatment of Wounds of the Heart in Ancient Times.

To arrest hæmorrhages and to arrest or prevent infection are still, as in the days of Celsus, the two dominant indications in the treatment of surgical injuries. The means for preventing infection are considerably elaborated at the present day, but were not wholly unknown to the ancients.

The prevention or arrest of sepsis is the crucial factor in the treatment of wounds of the heart. The cases recorded in the Daily Review of Foreign Literature (March 18th, 1918) illustrate this point.

[40] Journal of Medical Research, 1908.

[41] Johns Hopkins Hospital Bull., 1909.

[42] Matas: Ibid., p. 47. Ricketts published a work on "The Surgery of the Chest" in 1918. Chapter XI. is a review of the experimental surgery of the heart. He describes the following operations: valvotomy, valvectomy, valvoraphy, and valvopexy.

In early times wine and honey were used as a dressing for wounds. The good Samaritan poured in oil and wine. In Indian surgery ghee and honey is a common application. The value of honey for this purpose is probably due to its containing formic acid.[43] The Greeks made use of warm water and a "bitter root[44] crumbled in the hand," which "stayed the pain and dried the wound." The bitter root was probably peony, which still grows wild in Macedonia and is still used as a styptic.

Homer describes how a colonel, R.A.M.C., in the Greek army, Eurypylos by name, received a big flesh wound from an arrow in the thigh. The sweat ran down streaming from his head and shoulders, and from the cruel wound the black blood was welling. He was limping out of the battle when Patroklos came to the rescue:—

> "There stretched at length the wounded hero lay;
> Patroklos cut the forky steel away.
> Then in his hand a bitter root he bruis'd;
> The wound he washed, the styptic juice infus'd.
> The closing flesh that instant ceas'd to glow,
> The wound to torture, and the blood to flow."[45]

The Greeks in the Persian wars were far less equipped for the treatment of wounds than the Persians—e.g., the story of Pythos,[46] who was made into "butcher's meat" in a sea-fight, but was patched up by the Persian surgeons: "healing his wounds with myrrh and other herbs, and covering them all up in shield-slings or rolls of silky or fine linen." This is, I believe, the first authentic mention of a surgical bandage. The modern Greeks use ladanum[47] for wounds; it is the natural gum of a cistus or some such plant, dark green and smelling like Stockholm tar. My brother-in-law, Professor Myres of Oxford, held the rank of Commander R.N. during the war. He wrote to me of this cistus juice: "If I were a bacterium I should encyst at the sight of it! ...... I have tried it."

There is an impression that there was far less tendency for battle wounds to be septic in ancient than in modern times.

> "The difficulty of real knowledge of ancient things lies largely in the accident of our remoteness. We stand very far off, and have to strain our eyes. For us the comparison of ancient and modern is largely a comparison of something half seen at a distance with something which we know intimately ...... we see only the bold outlines ...... we are apt to miss the little lights and shades ...... we have not the knowledge or the sympathy to catch, across the gulf of years, the peculiar thrill of what was once a 'winged word' flying from soul to soul."[48]

Ancient and modern Greek weapons were, and are, cleaned with sand and sharpened on any convenient whetstone, such as a sandstone bridge-coping, or a sandstone well-head. We know that friction will sterilise a knife. Poisoned weapons were not thought fair in later Greek warfare. There were certain moral influences during the rise of the Greek Epic which ruled out poison in decent fighting. The fruit of the rise of another type of "kultur" in our own time was the introduction into warfare of poison gas and liquid fire.

> "The Iliad is full of battles and of battles fought with extraordinary fire. Yet the spirit of them is not savage. It is chivalrous. No enemy is ever tortured. No prisoners, with one exception, are ever maltreated."[49]
>
> "There is no doubt that the primitive inhabitants of Greece used arrows. The very word for poison means "belonging to an arrow." The arrows of Heracles in Hesiod had on the front of them—death and trickling drops. ...... Now in the Iliad poison has been completely cleaned off the arrow heads. Poison is treacherous, ungentlemanly; a weapon for low barbarians, not for heroes."[50]

"Greek poetry," writes Professor Murray, "was the embodiment of a force making for the progress of the human race. By progress I understand some gradual ennobling and enriching of the content of life—some movement towards the attainment of that "chief end of man," which is, according to the magnificent definition of the document known in Scotland as the "Shorter Catechism," "to glorify God and to enjoy him for ever."[51]

Barbed arrows—and Greek arrows were usually barbed—cannot be cleaned properly by the soldier. Most Oriental arrows were merely leaf-shaped and would be much more cleanly. The poison, when used on arrows, was probably obtained from the yewberry.[52]

There are some lurid septic details in Sophocles—e.g., the wound of Philoktetes, made by a poisoned arrow, ulcerated and caused an intolerable smell and intolerable pain, while the moanings of the hero so alarmed his companions that they shipped him off in a hurry from the Straits to Mudros. The medical service was lamentably defective; the patient was simply dumped on the beach with some "rags" and "iron rations"—just whatever they had! The remedy was as bad as the disease: little water, no food, no fuel, a dish of raw pigeons if you could hit them. The only people that were good to him were some V.A.D. nymphs from the water meadows!

The surgeon of to-day, looking over the works of Hunter and his immediate successors, cannot fail to be struck with the small place that surgical intervention then held in the treatment of disease and even of emergencies. The resources of surgery 100 years ago in dealing with the lethal consequences of disease and injury was so limited that the contrast with the present time is evidence of a wonderful evolution in our science during the last 40 years.

[51] Gilbert Murray: Ibid., p. 21. Additional remarks by Professor Gilbert Murray: "Hellenism was always in an uphill war against Paganism in the questions of human sacrifice, cruelty, slavery, the subjection of women and immorality" (p. 15). "Greek civilisation rose from the swampy level of the neighbouring peoples. Every Greek community is like a garrison of civilisation amid wide hordes of barbarians. Hellenism was represented everywhere by a handful of men holding an outpost, men who wrought their wonderful day's work in political and moral wisdom, in speculation, in beauty of outward form and inward imagining; with an ear ever open to the sternest of life's calls, and the hated spear and shield never far out of reach" (pp. 30-31).

[52] Yewberry (*Taxus baccata*). "Taxine, the alkaloid extracted from the leaves and berries, depresses the action of the heart in frogs, rabbits, cats, and dogs. It interferes with respiration and causes death in a short time through suffocation." Thorpe's Dictionary of Applied Chemistry, vol. v., 1913.

A Lecture

ON

THE AIMS OF THE WELSH NATIONAL MEDICAL SCHOOL.

WITH SPECIAL REFERENCE TO PREVENTIVE MEDICINE.

"FINEM RESPICE."

Being the Inaugural Lecture of

EDGAR L. COLLIS, M.A., M.D. OXON., M.R.C.S.,
MANSEL TALBOT PROFESSOR-DESIGNATE OF PREVENTIVE MEDICINE, UNIVERSITY OF WALES (LATE DIRECTOR OF WELFARE OF HEALTH, MINISTRY OF MUNITIONS AND H.M. MEDICAL INSPECTOR OF FACTORIES).

GENTLEMEN,—Three thoughts have influenced the choice of my subject to-day: 1. I form part of the Welsh National School of Medicine, whose name as a school is a great and ambitious one, unique among the medical schools of the United Kingdom. He who bears a high title, bears also concomitant cares and responsibilities—*atra cura sedet post equitem*. The title in the present case carries with it responsibility for educating and training in the best possible way those who, in the future, must hold in their hands the health of the Welsh nation. 2. The immediate future is to see the school reorganised and expanded, at a moment when the whole question of the teaching of medicine is receiving the most serious consideration; when doubts are openly expressed as to the efficacy of the scheme of training which has prevailed up to the present; when the health of the whole nation is being taken charge of by the new Ministry of Health; and when new knowledge of the human body in relation to health and disease is crowding in upon us. Serum-therapy, radiology, radiography, balneology, ionisation, dietetics, eugenics, osteopathy, to name only a few, all cry aloud to be included in a curriculum already overloaded with organic chemistry, anatomy, physiology, bacteriology, pathology, pharmacy, midwifery, gynæcology, surgery, curative medicine, the special departments of eye, ear, throat, and skin, lunacy, and fevers, and the great field of public health administration. 3. I personally am undertaking a heavy responsibility in that to-day I am the first occupant of the only chair in the kingdom devoted entirely to the subject of preventive medicine. There is no tradition to guide, no precedent to refer to; all must be wrought *de novo*. These three ever-present thoughts have directed me to fix the title which appears at the head of these remarks.

THE RISE OF MEDICAL SCHOOLS.

University schools.—The history of medical schools shows that they came into existence on no ordered plan. In the Middle Ages there were at such ancient seats of learning as Oxford, Cambridge, or Padua schools of medicine, where some famous physician presided over a band of students who came to sit at his feet. How he taught and what he taught, with no laboratories and no hospital beds, we can have but little idea. We can but suspect that many a practitioner of those days, looking back on his student times, must have thought:—

> "Myself when young did eagerly frequent
> Doctor and Saint, and heard great argument
> About it and about: but evermore
> Came out by the same Door that in I went."

Be that as it may, we can see that the trend of teaching must have been to the philosophic and more scientific side of medicine. Even to-day we see this tendency perpetuated. Oxford and Cambridge treat medicine essentially as a science; they lay down a scientific rather than a utilitarian groundwork; they deal only with preliminary subjects, and treat anatomy and physiology as pure sciences. Then the student passes away to learn the technique of his profession at one of the great hospitals. There, although the method of his training must persist, he is inclined to leave the sciences behind him as "Something accomplished, something done"; and opportunity is lacking for him to return again and again to the familiar laboratories and to his teachers for light and leading in the interpretation of the new facts he is being called upon to absorb.

Hospital schools.—At the same time as certain institutions, such as those of St. Bartholomew and St. Thomas, originally started as hostels for the poor, came to be devoted to dealing with the sick, hospitals as we know them to-day began to emerge. They were attended by physicians and later by surgeons (for I must remind you that surgery was, until the end of the eighteenth century, looked down upon by physicians and left to the barbers); these men had attached to them apprentices, the prototype of the medical student of to-day; and the system which existed can fairly be compared with that of the trade guilds and their apprentices. Many physicians, in no way connected with hospitals, also had their apprentices, just as lawyers to-day have their articled clerks, and hospital training was not a necessary part of the student's career. You may recall how, in 1811, the poet Keats was so apprenticed for five years to Mr. Thomas Hammond, a surgeon and apothecary of Edmonton; and bound himself "not to haunt taverns or playhouses, not to play at dice or cards, nor absent himself from his said master's service day or night unlawfully, but in all things as a faithful apprentice to [he shall] behave himself towards the said master and all his during the said term." After 3½ years Keats left Hammond and joined St. Thomas's and Guy's before becoming a Licentiate of the Society of Apothecaries. This apprenticeship system continued well into last century, and there are still doctors at work to-day who in their time served as apprentices. An excellent picture of how the medical student of the first half of nineteenth century carried on his work is to be found in Samuel Warren's book, "The Diary of a Late Physician," wherein is vividly described how one part of his duties was carried out—the resurrecting of a body for anatomy purposes in pitchy darkness on a cold night amid drenching rain; the details are realistically gruesome. But there is no elegy by Keats of such a churchyard scene. Perusal of this chapter must make every student of to-day thankful for the Anatomy Act, and prevent him from being a *laudator temporis acti*.

At the hospitals after a time, as the necessity for more scientific training became obvious, instruction in the preliminary sciences was arranged. But, with few exceptions, the university outlook has not been attained; and the training, although taking less and less notice of minor complaints and of the housing and occupations of the patients, has always retained an essentially utilitarian outlook; while, on the other hand, the universities have continued to preserve a more purely scientific point of view. Each side can claim advantages; broadly speaking, the great scientists, physiologists, and anatomists, are found attached to the University schools, and famous physicians and surgeons to the hospital schools.

Meanwhile, not only the teachers but the profession as a whole have been losing touch with the social life of the community. Teaching, in the first place, has been in the hands of the scientist and the specialising consultant, who have no intimate acquaintance with general practice. On the other hand, the general practitioner himself, called in to cure, has had perforce to confine his attention to the illness before him, for altered social conditions have conspired to narrow his outlook. The practitioner of the eighteenth century found his patients employed on the land or in some home industry, and he was familiar with their daily lives. To-day occupation is carried on in the mine, the factory, the mill, and the business house, not merely by men, but, to an increasing extent, by women also; and the doctor has lost touch with working conditions—those conditions which frequently supply the reasons for the illness he is treating. Thus he is unable to study the predisposing influences, to balance up cause and effect, and to act as a guide towards health and the prevention of disease.

The bearing of the above remarks upon the Welsh medical school, started on university lines, but about to reorganise and include also the hospital curriculum, is clear; the advantages of both systems have to be combined in one and their disadvantages made good.

THE RISE OF PREVENTIVE MEDICINE.

The science of medicine is associated in the minds of most people with the cure of disease. Disease is the point around which thoughts centre; and through the ages, from the time of Hippocrates onwards, attention has been mainly directed to remedies and treatment. The point of view has been that "they that be whole need not a physician, but they that are sick." Nevertheless, there is another great and rapidly growing side of medicine, of which traces exist reaching back into antiquity; I mean the prevention of disease. This side presents a point of view which centres thought on the positive entity, Health, rather than on the varied manifestations of lack of health which we sum up in the negative term, disease. Traces are to be found even in the Mosaic law aimed at preventing the spread of leprosy; isolation of the afflicted person was insisted upon: "he is unclean; he shall dwell alone; without the camp shall his habitation be"; and also disinfection by fire: "He [the priest] shall therefore burn that garment, whether warp or woof, in woollen or in linen, or anything of skin, wherein the plague is; for it is a fretting leprosy; it shall be burnt in the fire." There is also a passage in Jeremiah which recognises the two sides of medicine and might well be engraved over the portals of the Welsh School of Medicine: "Behold, I will bring it [the nation] health and cure."

It would be interesting to trace the history of preventive medicine through the centuries. The Greeks, for instance, not only had their god of healing, Æsculapius, but also their beautiful goddess of health, Hygeia, whose name is perpetuated in the word "hygiene"; and they had town water-supplies, since, according to Plutarch, Themistocles was able to erect a statue at Athens out of fines collected from those who diverted the public water-supply into their own grounds. The Romans had sanitary regulations: food inspection was under Ædiles Cereales; water-supply and sewers were under the Comites Cloacarum; and there were enactments against burial in the city. Rough-and-ready isolation against disease was practised in mediæval times. But the real seeds of preventive medicine were sown in the eighteenth century by such Englishmen as Sydenham, with his thoughts on epidemic disease; Mead, who advocated port quarantine against plague; and Jenner, who introduced vaccination against small-pox. In the nineteenth century came Farr and Simon, the architects of modern sanitary science; to be followed by the great Pasteur, whose epoch-making discoveries led to recognition of the cause of, and means for preventing, certain infectious diseases. Valuable as his discoveries proved to surgery in the hands of Lister, their value in preventing disease has even been greater. Take, for instance, the conversion of the pestilential Isthmus of Panama by Gorgas into a white man's country, which made possible the construction of the great canal; the world is thus in debt for its two great canals to the genius of France: the genius of Lesseps and the genius of Pasteur.

My time is limited, and I can only pause to remark that through the ages there has been a growing recognition of the necessity for a science of preventive medicine, and that this science has swung forward with giant strides synchronous with the advance in civilisation brought about by the industrial revolution of the nineteenth century. Previously, certain diseases, such as leprosy, had disappeared, no one knew quite why. Long before we knew the disease-carrying power of mosquitoes, drainage banished malaria from these isles, where it used to rage (as it does to-day in the tropics) in the morasses round Edinburgh, now the fertile Midlothian country, and in the fens of Lincolnshire. Cleanliness conquered typhus before we recognised the part played in its spread by the louse.

Thereafter the attack on disease has been clearly directed: typhoid has surrendered to pure water-supply and serum; vaccination has defeated small-pox; muzzling has stopped hydrophobia; cholera and plague are kept at arm's length by port quarantine; the tropical diseases—malaria and yellow fever—are eradicated by attacking the stegomyia and anopheles mosquitoes in their breeding-grounds; sleeping sickness, of which wild animals are carriers, is known to be transmitted by the tsetse fly, and the line of attack is thus apparent; typhus in the Serbian Army was overcome by elimination of the louse; infantile diarrhœa is coming under control through destruction of the domestic fly; scurvy and beri-beri have surrendered to suitable vitamines in food; rickets seems likely to follow; scarlet fever under rigid isolation is losing its terrors; we protect to-day against diphtheria, against common colds, and even influenza; hospital gangrene and sepsis have collapsed before Listerism and asepsis; puerperal fever only lingers as a reproach to the accoucheur in whose practice it appears.

These instances of the abolition of certain types of disease would, however, only be matters of passing interest if the general health remained at its old level; if the removal of one disease merely left an unresisting population to fall victim to others; if the tendency of the sick to be sick remained unaltered; if the vigour of the nation were not increased; for, as Martial expressed it, "*non est vivere, sed valere vita*" (the joy of life is not in living, but in health). But evidence exists that vigour is greater; the death-rate from tuberculosis has, since 1860, fallen 50 per cent. among males and 67 per cent. among females, as the general well-being, expressed in better food-supply, has been rising; infant mortality has fallen from 154 per 1000 children born in 1851–60 to 105 in 1911–18, and the death-rate of England and Wales, which was 20·6 per 1000 living in 1868, had fallen to 13·5 in 1917.

The debt the nation owes to preventive medicine is written in the lives of us all in letters of gold, for a nation's wealth is that nation's health. If I had been speaking some century ago instead of in 1919 my audience would have been smaller. Some of us would have succumbed in infancy; others of cholera; others of typhoid, of typhus and gaol fever, which attacked the judges and witnesses in court as well as the prisoners; others of malaria; more still of consumption; others of small-pox, while any woman present would be an outstanding beauty if not pock-marked to indicate that she had passed through her attack of that national scourge. From a financial aspect we should have had to pay higher for life insurance, but lower for pensions because few could be expected to benefit thereby. Preventive medicine has indeed a proud record, but many a field lies ahead for us to cultivate.

The Official Status of Preventive Medicine.

In contradistinction to curative medicine the preventive side has not been particularly associated with either the university or the hospital schools. It has developed independently, and its distinguishing characteristic has been its official status. This it has acquired through the will of the people expressed in Acts of Parliament, the list of which is long—the Vaccination Act, Notification of Deaths, Public Health and Factory Acts, Burial Act, Housing, Midwives, Employment of Children, Protection of Food, Notification of Births, Education Acts, Old Age Pensions, Health Insurance, Notification of Tuberculosis, and still the list is incomplete. Taken collectively, these Acts represent the most remarkable instance—one to which social economists have not drawn attention—of nationalisation, the nationalisation of health. This body of legislation is an expression of an ill-defined feeling that all is not well; and of the nation struggling, and with a fair measure of success, though until recently on no coördinated plan, to take charge of, protect, and improve its most precious possession, health.

Preventive medicine has lacked one essential to complete success which curative medicine has possessed, although, as already pointed out, it is not stressed in modern medical training. Curative medicine, which, by the way, has never been official, has always been personal to the sufferer; and intimate relations have always existed between the patient and his doctor. Now a doctor, by his very name, should be a teacher; but the doctor, when sent for, is sent for not to teach but to cure; and the public, accustomed to come into personal touch with the profession in cases of illness only, has failed to recognise the personal application of the proverb that prevention is greater than cure.

Possibly I may seem to be drawing too clear a distinction between preventive and curative medicine; if so, it is only for convenience in presenting the case, for I agree that "the aim of treatment in every case, whether preventive or curative, is to remove or counteract the agencies which threaten to produce or have produced the abnormal. In most cases preventive and curative treatment do not differ in kind."[1]

The impersonal character of much preventive medicine of the past is clearly seen in the recommendations of the Royal Sanitary Committee, whose report[2] led up to the Public Health Act, 1875:—

1. The supply of wholesome and sufficient water for drinking and washing.
2. The prevention of the pollution of water.
3. The provision of sewerage and utilisation of sewage.
4. The regulation of streets, highways, and new buildings.
5. The healthiness of dwellings.
6. The removal of nuisances and refuse, and consumption of smoke.
7. The inspection of food.
8. The suppression of causes of diseases, and regulations in case of epidemics.
9. The provision for the burial of the dead without injury to the living.
10. The regulation of markets, &c., public lighting of towns.
11. The registration of death and sickness.

No one can gainsay the value of action on these lines, and I have referred to some of the benefits that have accrued; but each member of the community is only interested in these matters in a half-hearted way. The man in the street does not understand mortality-rates or life-tables; infant mortality does not excite him; he takes his water-supply and public sanitation for granted; he avoids a sewage farm, and pours smoke into the atmosphere if he can get coal for the purpose. He only becomes vocal amid a plague, like influenza, which he is sure is someone's fault, not his own. There have been no health practitioners visiting and talking things over as the family doctor talks over the family treatment of measles, bronchitis, indigestion, headache, sciatica, and the like. More personal interest is needed; and recent advances in preventive medicine are already supplying the need. Maternity and infant clinics are dealing with the individual mothers and babes; and their success is remarkable. School medical inspection and school clinics are similarly personal, and are accepted without demur. Home-visiting arising out of the above, and in connexion with tuberculosis work, is carrying the apostles of health into the home. Welfare supervision and safety-first work in factories are appealing directly to each worker. Thus preventive medicine is steadily becoming more personal and more popular.

Personality in Industry and Health.

I would venture on a comparison by saying that the nineteenth century discovered the general principles of sanitary science, just as in industry it discovered the principles underlying the use of power-driven machinery. Machinery has revolutionised civilisation. Sanitation is revolutionising national health. The twentieth century in the industrial world is now discovering the individuality of workers; the value to output of selecting the right man for each task; the value of shortened hours of labour and organised rest-pauses, of health supervision and industrial canteens. The discovery in the world of preventive medicine is similarly the importance of the individuals who collectively form the nation. In industry the maximum output depends upon the worker as a human being; no matter what inventive genius is applied to improving mechanical appliances, it is the man at the machine who determines the output, and who can increase or decrease that output in proportion as he is physically and mentally healthy and fit. In the field of preventive medicine the provision of pure water, perfect drainage, and clean air cannot compel an unwilling public to drink at the clear spring of health; everything must finally depend on the individual if the health of each is to be ensured, if the nation as a whole is to become A 1. Sir George Newman, after pointing out[3] that as the nineteenth century was drawing to a close preventive medicine became more personal, social, and apposite than formerly, based more on the child, was concerned more with the individual than with the environment, goes on to say: "In the last decade of the nineteenth century came the London Public Health Act, legislation on housing and on industrial betterment, on the cleansing of persons as distinct from properties, and on the education of blind, deaf, and defective children, the provision of school meals, the protection of food, the notification of births, the medical inspection and treatment of children, the Children Act itself, old age pensions, the health insurance of the adolescent and adult, and a group of Acts concerned directly with some of the prevalent diseases, tuberculosis, mental deficiency, ophthalmia neonatorum, and the venereal diseases. No individual planned this significant sequence, no single factor explains its emergence. It represents a new social spirit, a new application of science to the life and labour of man."

---

[2] Report of the Royal Sanitary Commission, 1871, vol. i., p. 20.

The Coming of the "Health" Nurse.

Now turn to another comparison between curative and preventive medicine. Curative medicine was confined to medical practitioners until the middle of last century, when, arising out of the inadequacy of hospital work disclosed in the Crimean War, Florence Nightingale called into existence the hospital nurse. How the profession worked previously at the mercy of Sarah Gamp and her invisible colleague, Mrs. 'Arris, is difficult to-day to imagine. But a true mate has been found, and the trained nurse is an integral part of the medical profession. She in her turn has called into existence the invaluable hospital almoner. Meanwhile the trained midwife is rapidly replacing her prototype and becoming indispensable throughout the land; she bids fair soon to relieve the practitioner to a great extent of her side of his work; her sphere of activity, which is prevention rather than cure, provides an excellent instance of the inseparability of the two sides of medicine.

Preventive medicine is treading close on the heels of his elder brother, and in seeking for a mate has called into existence a new type of nurse, the health visitor; and she is becoming as necessary in her field of work as is the trained hospital nurse in hers. Her predecessor, if she had one, was the village nurse and district visitor. To-day she is wanted in the maternity and infant clinic; she is necessary to the school clinic and tuberculosis dispensary; home visitation is in her hands; and she is needed in the factory. Her work is ever expanding in the city and on the countryside. Her importance to the future of preventive medicine, to its immediate and personal application, is immense.

THE TASK TO BE ACCOMPLISHED.

What is then the task which lies before the Welsh National Medical School? What are its responsibilities? It has to train a whole and complete medical service for the Principality so that there may be established throughout Wales a capable and well-equipped band of apostles preaching the gospel of health on hill and dale, in hamlet, village, and town. The band must be complete, medical men and women, general practitioners and consulting specialists, medical officers of health, school officers, factory officers, maternity and infant welfare officers, tuberculosis officers, and trained nurses, hospital almoners, midwives, health visitors, and welfare supervisors. Each and all recognising the place they have to fill in the life of the nation, the dependence of that life upon their work, and the high duty they undertake when entering our profession; but strengthened for their work by being bound together by the bond of a common *alma mater*; imbued with the high aspirations she will have inspired, returning to her from time to time, bringing with them the wealth of accumulated experience, and acquiring in return up-to-date information as to improvements and advances in knowledge.

The Means to Attain the End.

There are available means, general and local, for the purpose in hand.

1. The general experience of the past, and of other places enables that which has proved best and most successful to be selected, and that which has proved less successful, or even disadvantageous, to be avoided. Veneration for antiquity must not be allowed to hamper, nor adhesion to the new because it is new. "Affectations of antiquity and novelty are the humours of partisans rather than judgments."[4] As Clough has expressed it—

> "Old things need not be therefore true,
> O brother men, nor yet the new;
> Ah! still awhile the old thought retain,
> And yet—consider it again."

2. The local facilities include: (*a*) A university college able and ready to provide instruction in all knowledge ancillary to medicine, whether in social economics or psychology, or in the physical sciences of chemistry, physics, botany, or biology; (*b*) a medical school already flourishing, in which the training is on scientific or university lines, a school whose numbers have outgrown its buildings, and for which new accommodation is being provided; (*c*) a hospital, the King Edward VII. Hospital, second to none in modern equipment, and ready at hand for providing clinical instruction in every branch of curative medicine, surgery, and midwifery; (*d*) a unique organisation in the King Edward VII. Memorial for Wales to provide instruction in every branch of tuberculosis work; (*e*) excellent mental and fever hospitals adjacent (and the authorities of the former are even now taking steps to develop, through a mental clinic, the preventive side of nervous diseases which has been neglected far too long); (*f*) Cardiff and Glamorgan possess maternity and infant welfare and school clinics, ready for providing instruction as regards the health of mothers, babes,

[4] Novum Organum, Bk. I, lvi.

and growing children, who represent the spring-time of life when the seeds of future disease are planted; (*g*) the district is sufficiently industrial to enable industrial medicine to be studied, the mental and physical value of occupation and exercise, the aggravation of ill-health associated with drudgery and fatigue; (*h*) it is sufficiently populous to afford facilities for study of social economics, a volume of knowledge too long unopened by our profession; (*i*) Cardiff is a great port where quarantine can be seen in action, and acquaintance made with tropical diseases; (*j*) there are also important possibilities in the adjacent flourishing towns of Swansea and Newport; (*k*) of immense importance, also, is the Ministry of Health for Wales, in the hands of men with wide vision, able and ready to give invaluable advice and enthusiastic support; (*l*) there is the Prince of Wales's Hospital for after-care of surgical cases; started for maimed soldiers and sailors, it is about to be opened for the treatment of civilians injured in the stress of life; (*m*) last, but by no means least, owing to the generosity of Sir W. J. Thomas, there is the Preventive Medicine Institute now being built, the work of which must permeate the whole or the *raison d'être* of its existence will not be fulfilled. Here is a new thing established in connexion with a medical school, established at a most interesting moment in its existence.

This institute stands to represent not only teaching but also research and the spirit of research. For, as Sir Walter Morley Fletcher has recently written,[5] "The importance of linking research work with university teaching for the gain of each is so universally admitted as to need no discussion." The institute must be acquainted with the health conditions of Wales and be prepared to direct research to meet the needs of the Welsh nation; it must have knowledge of social conditions with which health is so intimately associated; it must be alive to industrial conditions and be prepared to investigate why the industrial worker so often fails to maintain a high standard of health and so is unable to give of his best to the community which he and we all serve; it must note variations in sickness and mortality in different districts and be prepared to assist in searching out the causes and finding the way to remove them, "for where the cause is not known the effect cannot be produced."[6] Its scope must, in short, so far as medicine is concerned, be as broad as that proudly claimed by Bacon, who took all knowledge for his own.

The Next Step.

All these varied organisations and institutions have to be called in to build the structure of our National School of Medicine. The work of coördinating the whole will be no mean task. The conditions are, however, favourable; not merely because the development of the school is looked on with favour, and recognised as a need in the Principality, but because the development of such a coördinating central nervous system for pre-existing units represents the normal process in nature. Nature does not start with a central nervous system and attempt through it to force into existence peripheral units; such a husteron-proteron proceeding is only favoured by "constructive politicians," "Nature to be commanded must be obeyed."

A scheme of instruction must be evolved which will consider afresh the needs of the community the school has to serve. Nor are the needs of Wales only for consideration. Wales is a part of a great world-wide empire, and her sons and daughters go forth to the uttermost parts of the earth; they must be equipped for their work. The duty of the school is imperial as well as national.

The position of the student and the time at his disposal present other important aspects. For adequate teaching of all that each specialist would desire many long years would be required; the students would still remain with their education incomplete at 40, and would finally only issue forth as grey-haired and reverent seniors, to do but a few short years of work before becoming old-age pensioners. Here let me quote again from Sir George Newman.[7] "The object of medical education is not the completely furnished encyclopædic; but the equipped man, alert, ready, trained, with an expanding and enlarging mind, the dexterous and willing instrument of knowledge, technical craft and progress, whatsoever its destination." He goes on to discuss a reduced and simplified curriculum, and states under six headings how to make the study deeper and the training more effective; the fifth heading is of special interest: "Associated with treatment, is the large issue of preventive medicine, in which something approaching revolutionary reform is needed. The ordinary medical student does not require a course of study comparable to that prescribed for the Diploma in Public Health. He is not a 'diminutive' medical officer of health. The knowledge of preventive medicine he requires is something deeper and more intimate than an administrative function or dealing with an environment, more innate than a collection of memorised data; it is such an understanding of the nature of disease that its occurrence can be prevented or it can be checked in the patient before disablement; in short, a curative medicine which is preventive. Its application is not restricted by law or confined by expediency; it is universal. It concerns almost all disease, and not infectious disease only. To express it crudely, death under 50 or 60 years of age has got to be prevented or avoided, and the medical practitioner is the primary agent in the task."

Sir George Newman in here setting a standard is considering only the medical student; but we have to aim higher still, since the Welsh medical school is part of a university. We must send forth men with the mark upon them of a university, a place which Cardinal Newman once defined as a "school of universal training." The general world of culture must be to them an open house, into which they have found their way through university life with minds broadened by exchange of thought and intercourse with teachers and fellow-students in other schools than their own.

Here is the standard we have to aim at and attain; then those who go forth to their work, taught to be—

> "...... inquisitive how pricks and cracks
> Befall the flesh through too much stress and strain,"

will be able to look back on their student days and say (giving a turn to Browning's words):—

> I own the Past profuse
> Of power each side, perfection every turn:
> Eyes, ears took in their dole,
> Brain treasured up the whole;
> Should not the heart beat once "How good
> to live and learn?"
> Not once beat "Praise be Thine!
> I see the whole design."

[6] Novum Organum, Bk. 1, iii.

[7] Some Notes on Medical Education in England, Sir George Newman, 1918, pp. 116–7 (Cd, 9124).

HOW THE PURPOSE IS TO BE EFFECTED.

The exact way in which the purpose will be effected lies to-day on the knees of the gods. No one can draw back the veil from the future. But the gods help those who help themselves. If after determining upon the end to be attained we adopt the motto *Finem respice*, and if the means to attain that end are present, as they are, nothing can stay the will to succeed. That will is present; it has moved mountains to construct the position as it exists to-day, compared with which the difficulties ahead will be but as molehills. Those who are to be privileged to carry on the work owe deep gratitude to the men who have toiled before, bearing the heat and burden of the day; some have succumbed in the struggle, like Colonel Bruce Vaughan.

Personally, while recognising the magnitude of the task ahead, I bow to these pioneers who have enabled me to say, "The lines are fallen unto me in pleasant places; yea, I have a goodly heritage."

ON THE
SERUM-DIAGNOSIS OF SYPHILIS,
WITH SPECIAL REFERENCE TO THE STANDARDISATION OF RED BLOOD CELLS AND COMPLEMENT.

BY FREDERICK C. LEWIS,
ASSISTANT LECTURER IN BACTERIOLOGICAL METHODS, UNIVERSITY OF LIVERPOOL.
(From the Bacteriological Laboratories of the City and University.)

It is now well recognised in the laboratory diagnosis and control of syphilis and other pathological conditions in which the phenomenon of complement-deviation is applicable that accurate standardisation of the materials used is essential. Varying or contradictory results are generally ascribed not to any prime fault in the method, but rather to errors in technique due either to inaccuracy or omission of standardisation.

Several good methods are now made available through various publications in which the problem of standardisation has received very thorough attention. The writer, however, ventures to suggest, as one result of his work with Professor J. M. Beattie, that more attention should be paid to the standardisation of the red blood cell suspension. In the test as ordinarily carried out the terms negative, slightly positive, positive and strongly positive, or terms of similar import, are used not to indicate the presence or otherwise of active disease in the patient under examination, but rather the capacity of the patient's serum to absorb minimum hæmolytic doses (M.H.D.) of complement in the presence of the artificial antigen. It therefore follows, in order that results of one laboratory should be comparable with those of another, that the term minimum hæmolytic dose of complement should be rigidly defined, and its actual value in hæmolytic work uniformly established.

Inaccuracies Arising from Lack of Standardisation.

If the M.H.D. used by a worker at one time is less powerful than that used by him on another occasion owing to its being titrated against a less dense blood cell suspension his results, on this ground alone, will vary. Other things being equal, a powerful M.H.D. will swing his results to the negative side, and a less powerful M.H.D. will swing his results to the positive side. If this be true of an individual worker the variations will probably be accentuated if the same serum be examined in different laboratories. In an extreme case, for the sake of illustration, if a given syphilitic serum absorbed in the presence of antigen say 5 M.H.D., when M.H.D. = x, the same serum would absorb only $2\frac{1}{2}$ M.H.D if M.H.D. = 2x. Now if 5 M.H.D. were used in the second experiment the result would be complete lysis (i.e., negative) owing to $2\frac{1}{2}$ M.H.D. being free, whereas in the first case the result would show no lysis (i.e., positive) owing to there being no free complement, in each case the value of the M.H.D., although different, being determined by titration against the particular red cell suspension used. Again, if the value of the M.H.D. be small there is a danger of the native anticomplementary power of the serum becoming so obvious that the whole result is vitiated; that is to say, if a given serum owing to its anticomplementary power absorbs $1\frac{1}{2}$ M.H.D. when M.H.D. = 2x, it will absorb 3 M.H.D. if M.H.D. = x. Thus, if 3 of the weaker M.H.D. be used in the test there will be no lysis, not because the serum is positive, but because the serum itself has absorbed all the complement; whereas if the stronger M.H.D. be used $1\frac{1}{2}$ M.H.D. would remain for interaction with antigen and syphilitic ambocepter or lysis, as the case may be. These considerations may in themselves explain the occasional occurrences of several sera, usually in one series of tests, showing high anticomplementary values in the absence of antigen.

Now, the M.H.D. of complement is generally accepted as that minimum amount of complement which will hæmolyse a given quantity of sensitised red cells, primarily that is, it is defined in terms of red cells. In the writer's opinion it should be more rigidly defined—namely, that minimum dose of complement in unit volume which causes complete hæmolysis of a unit volume of *a standard suspension of sensitised red cells* under definite condition of time and temperature. If there be any variation in the strength of the red blood cell suspension the quantity of complement per M.H.D. must also necessarily vary and thus more or less influence the results of the final test. In other words, the strength of the red blood cells suspension must, within the limit of experimental error, be invariable.

Technique Now in Use.

In the various methods published by the Medical Research Committee[1] reference is made to the red blood suspension as follows. Harrison says: "The strength of the suspension which is used in the test is 3 per cent. to 5 per cent., *according to the practice of the individual worker.* ...... I, personally, prefer a 3 per cent. suspension." In this case the blood is "spun until the cells are deposited." Browning uses "3 per cent. of washed sediment." Fildes and Mackintosh advise "...... three washings in all, and use 1 c.cm. deposited washed corpuscles + 19 c.cm. saline" in their test (i.e., 5 per cent.). In method No. IV. in the Medical Research Committee pamphlet the blood is, after dilution, &c., spun until the "cells are all deposited" four times, and used in a 6 per cent. suspension of the deposit, which becomes 3 per cent. in the actual test by dilution with amboceptor. In all these methods, therefore, the blood is centrifuged and made up to a certain percentage in normal saline—namely,

---

[1] Medical Research Committee Special Report, Series No. 14.

3 per cent. or 5 per cent., and presumably giving on titration correspondingly different values to the M.H.D. A point which this communication emphasises is that, apart from the varying percentages used and the difficulty of making such percentages accurately, considerable variation in the number of corpuscles per unit volume of deposit also occurs, according to the speed of the centrifuge and the length of time given to the process. In an actual experiment the blood, after washing, &c., was spun until the cells were just deposited and the supernatant fluid clear; the volume of the deposit was then 9·5 c.cm. Without disturbing the deposit, the tubes were again spun for 30 minutes longer; the volume was then 7 c.cm.

In the absence, therefore, of precise instructions as to the technique to be followed, differences in the strength of the blood suspensions would appear to be inevitable. If such differences exist then the value of M.H.D. must also necessarily vary.

Illustrative Experiments.

These differences are shown in the following illustrative experiment, where four different suspensions of sensitised red cells were used.

I. Blood washed and finally "whirled" until the cells were deposited, diluted to a 5 per cent. suspension.

II. Similar suspension to No. I., except the "whirling" was extended for an additional 30 minutes, and the deposit made up to 5 per cent. suspension.

III. Same as No. II., but 10 per cent. suspension used.

IV. Suspension made up as detailed below.

In each case the cells were sensitised in the usual manner and complement added. The usual precautions were taken to ensure thorough mixing and adjustment of total volume.

TABLE I.

Suspension.	Complement in volumes.											
	1	2	3	4	5	6	7	8	9	10	11	12
I.	Nil	T	SH	H	H	H	H	H	ACH	ACH	ACH	CH
II.	,,	Nil	,,	,,	,,	,,	,,	,,	H	H	,,	ACH
III.	,,	,,	Nil	T	SH	SH	,,	,,	,,	,,	H	H
IV.	,,	T	SH	H	H	H	,,	ACH	ACH	CH	CH	CH

Nil = No hæmolysis.
T = Trace of hæmolysis—that is, very slight tinting.
SH = Slight hæmolysis—that is, colour slight but deeper than "T."
H = Hæmolysis more or less marked, but not complete.
ACH = Almost complete hæmolysis—colour deeper red with small deposit of red cells.
CH = Complete hæmolysis—no deposit or very slight practically colourless deposit.

The tubes were incubated in water-bath for one hour at 37° C. and results read the following morning, when the non-hæmolysed cells had deposited.

It will be observed that with suspensions II. and III. the experiment did not indicate a minimum hæmolytic dose—that is, it was greater than 12 volumes of complement, whereas the M.H.D. of suspension I. was 12 volumes of complement, and that of suspension IV. was 10 volumes of complement. Excluding suspension No. III., which perhaps was stronger than anybody would ordinarily use in a test, we have three suspensions each with a different M.H.D. and each of which could be used ordinarily in a test. The first one was an ordinary 5 per cent. suspension, the second had merely been centrifuged for a longer period. The third was made up according to details given below.

In reference to Nos. I. and IV. in which the M.H.D. was shown the following observations may be made: Taking the first case M.H.D. = 12 and in the second M.H.D. = 10, and using these quantities in a test, with 3 M.H.D. and 5 M.H.D., as in Harrison's method, we have the following:—

A. Suspension I. 3 M.H.D. = 36 volumes
B. Suspension IV. 3 M.H.D. = 30 ,,
Showing a difference of 6 volumes.

That is, if these two suspensions were used in two tests with the same sample of serum at the same time, there would be a difference in the amount of complement equal to 3/5 M.H.D. (M.H.D. = 10). This point is further demonstrated in the case of the tubes containing 5 M.H.D.

A. Suspension I. 5 M.H.D. = 60 volumes complement
B. Suspension IV. 5 M.H.D. = 50 ,, ,,
Showing a difference of 10 volumes—that is, a difference of 1 M.H.D. (M.H.D. = 10).

It will, I think, be recognised that such variation in the actual amount of complement used, as in taking 5 M.H.D.'s, may make a difference of one whole dose in relation to two different suspensions of cells will possibly introduce serious errors in the interpretation of the results. Especially is this the case when the difference between the blood suspensions, as in Nos. I. and IV., is very slight, as evidenced by the appearance of the first nine tubes in each set (see Table I.).

A further illustrative experiment is now given. The volume of some freshly washed and deposited red cells was measured and suspensions made up respectively to 6 and 10 per cent. in normal saline. Two other tubes of blood, previously measured and found jointly to contain 9·5 c.cm. of deposit, were centrifuged for a further 30 minutes, this, as previously mentioned, effecting a concentration of the cells to 7 c.cm. These were made up to 10 per cent. A further standard suspension was also made. In each case the cells were sensitised before adding the complement by adding the necessary quantity of diluted amboceptor in saline, thus bringing down the percentage to 3 per cent. and 5 per cent. respectively and halving the concentration of the standard suspension.

TABLE II.

A. 3 per cent.	suspension,	M.H.D.,	3 vol. complement.
B. 5 ,,	,,	,,	4 ,,. ,,
C. "Standard"	,,	,,	5 ,, ,,
D. 5 per cent. concentrated	,,	,,	5–6 vol. (say 5·5) ,,

Similar differences are here to be noted, as in the previous table (I.)—namely, four suspensions of sensitised red cells, (A) and (B) in the strength commonly used, (D) a possible variant of (B) and another (C), all required different minimum quantities of the same diluted complement to bring about complete hæmolysis. If multiples of these doses had been used in testing four portions of a given serum (say X 3 and X 5) complement would have been used in quantities as follows:—

Suspension A.	9 volumes	and 15 volumes.
,, B.	12 ,,	and 20 ,,
,, C.	15 ,,	and 25 ,,
,, D.	16·5 ,,	and 27·5 ,,

Taking suspension A as a basis for comparison,

B would have	3 and 5	vols. of complement.
C ,,	6 and 10	,, ,,
D ,,	7·5 and 12·5	,, ,,

more than that apportioned to A.

Now in terms of the M.H.D. as found with suspension A.

Serum with B receives	1 and 1·6	M.H.D. in excess of A.
,, C ,,	2 and 3·3	
,, D ,,	2·5 and 4·1	

Thus if the serum used was only just sufficiently positive to inhibit hæmolysis with suspension A and one multiple of the M.H.D. of A, partial or complete hæmolysis would occur in all the tubes used with suspensions B, C, and D. A positive result would be indicated if suspension A were used, and slightly positive or negative results would be indicated with suspensions B, C, and D. That these absolutely contrary results do not occur frequently in well-established practice is, I think, due to the fact that strongly positive sera can stand against a considerable excess of complement and frankly negative cases absorb so little complement in the main that they do not adversely affect the result even when, owing to a weak blood suspension being used, relatively small doses of complement are included in the complex. These and similar results would appear to indicate that further standardisation of the red blood cell suspension is essential.

Method of Standardisation.

The method suggested for the standardisation is as follows:—The blood is collected, defibrinated, washed, and deposited in the usual manner. The deposited red cells are then mixed with three or four times their volume of normal saline. A 25 or 50 g. specific gravity flask is weighed accurately (*a*) dry and (*b*) filled with normal saline. This saline is then thrown out and replaced with the heavy suspension of red cells and reweighed. In these weighings the usual precautions are taken, such as the accurate filling of the flask, and the weights are taken at 60° F. This latter is accomplished by immersing the specific gravity bottle, saline, and suspension in a water bath at 60° F. The relative weight of the red blood cell suspension against normal saline at a constant temperature is thus calculated, and this can be utilised as a basis for the further dilution of the suspension.

This method is not a true specific gravity method, for as such it would be necessary to use distilled water as a basis for comparative weight and also for dilution, this latter being, of course, obviously inadmissible. I have found that a relative volume-weight of 1·0040 is a suitable dilution for use, and that the M.H.D. of complement based on such a suspension of red blood cells gives a good range of results in weak positive, positive, and strongly positive cases.

The following is an illustrative calculation in the preparation of the standardised suspension; a 50 g. specific gravity flask was used.

A. Weight of flask = 22·265 g.
B. Weight of flask and saline = 72·404 ,,
C. Weight of saline (by difference) = 50·139 ,,
D. Weight of flask and blood suspension = 73·229 ,,
E. Weight of blood suspension (by difference) = 50·964 ,,
F. Relative weight of blood suspension $= \frac{E}{C} = 1{\cdot}0164$,,
G. Relative weight of required suspension = 1·0040 ,,
H. Dilution necessary to reduce F to G $= \frac{0{\cdot}0164}{0{\cdot}0040} = 4{\cdot}1$

Hence, to obtain the necessary dilution one volume of the strong red cell suspension is added to 3·1 volumes of normal saline—i.e., 31 c.cm. of normal saline is added to each 10 c.cm. of the strong suspension.

Remarks.

An attempt was made to standardise the red cell suspension by the estimation of liberated hæmoglobin by means of a clinical hæmoglobinometer, but this method was ultimately abandoned principally owing to the error inevitably introduced in the final colour-matching. With the adoption of the "relative weight method" a standard suspension is obtainable, in which the errors due to making up the percentages and the possibly large errors introduced by variations in centrifugalisation are eliminated.

It may perhaps be justly claimed that this method of standardisation of the red blood cell suspension will give a practically unvarying concentration of red cells for every series of tests, and will establish a standard value for the term "minimum hæmolytic dose" of complement. It is not claimed that this method of standardisation is any considerable advance in technique because many thousands of excellent results have been obtained without it. The previous lack of such a standardisation may, however, partly explain the known differences which exist between the results obtained on the same serum by different workers.

The method will minimise a source of error, especially in repeated tests and in comparative work generally, and may assist in those "border-zone" cases of mild or doubtful infection and in cases which have been well treated. It is in these difficult cases that very accurate standardisation is essential, but probably less so in frankly positive and negative sera.

Other methods may suggest themselves to other workers, but in the meantime, in the writer's opinion, a fixed standard red cell suspension used in unit volume and, as a corollary, the establishment of a uniform value to the term "minimum hæmolytic dose" of complement is, if not essential, at least desirable. The adoption of this or a similar method involves extra labour. It does not simplify the technique, it rather adds to the demands on the worker. If, however, there is a gain in accuracy the extra time involved will be well spent.

In conclusion, my best thanks are especially due to Professor Beattie and also to various colleagues with whom I have discussed the subject matter of this contribution.

A GERMAN BULLET EMBOLUS.

BY H. J. B. FRY, M.D. OXON.,
CAPTAIN, R.A.M.C. (T.F.); PATHOLOGIST, NO. —— GENERAL HOSPITAL, B.E.F., FRANCE.

THIS case is recorded as a remarkable instance of the migration of a rifle bullet in the venous blood stream. Previous cases have been noted of the movement of foreign bodies in the vascular system by Grangérard,[1] Lyle,[2] Gregory,[3] O'Neill,[4] and Menuet.[5] Bland-Sutton[6] quotes a number of cases, of which the one here described forms one. In this instance there was a small oval wound of entry a half-inch below the left anterior superior iliac spine. It will be seen below that the bullet entered the vascular system by gouging the posterior aspect of the left external iliac artery and penetrating into the lumen of the left internal iliac vein, causing an arterio-venous aneurysm of these vessels. From this position the bullet was carried up the common iliac vein and the inferior vena cava. It passed through the chambers of the right side of the heart, through the pulmonary valve into the left branch of the pulmonary artery (vide Plate I., A), where it impacted as an embolus in one of the branches supplying the lower lobe of the left lung, thereby causing two infarcts in this lobe (vide Plate I., B, C). Keith,[7] in discussing intra-cardiac bullets, had drawn attention to the necessity of determining the site of entry of such bullets into the circulation and the reason for their entry without much hæmorrhage, and stated that there was no record of a bullet being carried into the pulmonary artery. Such a tortuous and deflected course as the above is in itself remarkable, but, in addition, there was no injury to be found in either of the veins along which it travelled or of the flaps of the tricuspid and pulmonary valves through which it passed. It is astonishing, on consideration, that the bullet should not have been entangled in the meshes of the chordæ tendineæ and musculi papillares of the right ventricle. Moreover, there was never any pain or discomfort referred to the heart or the lungs. The question naturally arises whether this bullet could have found its billet by any other path. The clinical evidence and post-mortem findings prove without question that the bullet could only have reached its final situation by the above route, as there was no other wound of the body and no other place of entry into the vascular system except the above-mentioned aneurysm.

The history and course of the case present some interesting features in addition to the post-mortem findings. The notes of these are therefore added.

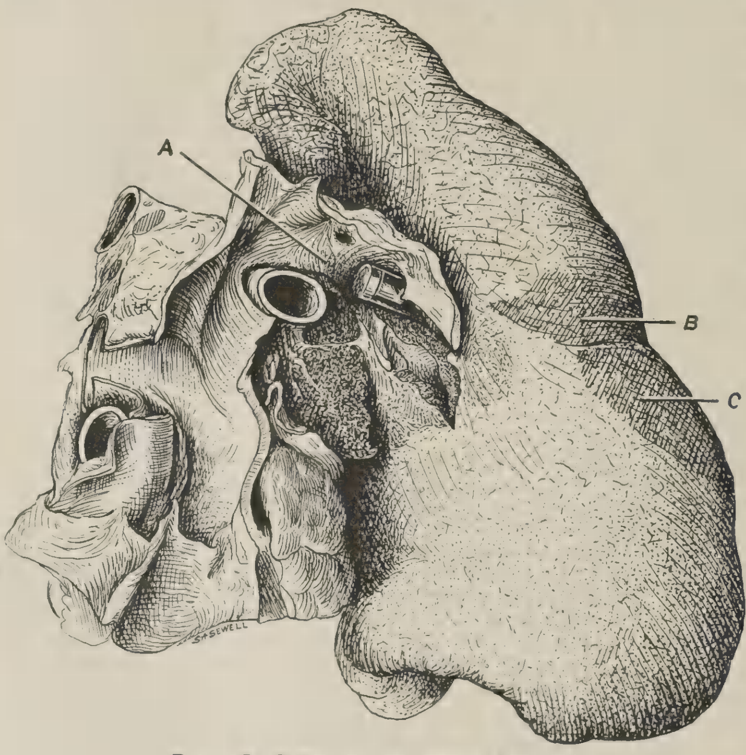

PLATE I.—Pulmonary artery and left lung.

Clinical Abstract.

The patient stated that he was standing by his battery position on April 2nd, 1918, when he suddenly felt a sharp stinging pain in the left foot, and thought that he had been hit there by some missile. His boot was taken off, but no wound could be found. He was unable to walk and was carried to the field ambulance, where his leg was examined and found to be swollen and congested. A small wound below the left anterior superior iliac spine was found, but nowhere any wound of the leg.

On admission to this hospital a small, oval, suppurating wound, apparently superficial, was present immediately below the left anterior superior iliac spine. There was no evidence of penetration and no track could be found. The left foot was puffy and discoloured, and there was no capillary reaction. No pulse could be felt at any point in the leg. A widespread ecchymosis beneath the skin of the left loin and left iliac fossa and a well-marked humming murmur heard at its loudest about $2\frac{1}{2}$ inches below and to the left of the umbilicus, together with a thrill, afforded a diagnosis of an aneurysm of the left external iliac artery. The whole of the left leg was considerably swollen and œdematous. The patient continually complained of much pain in this leg. The temperature was normal on admission, but the pulse was rapid, 100–120, full, but of low force and tension. The pulse-rate was rapid throughout the course of the illness. X ray report was: "No evidence of F.B. from level of umbilicus to knees."

For a week the patient's general condition remained good. There was some collapse of the bases of both lungs. A hæmic systolic murmur was present at the apex of the heart, and it was especially loud in the pulmonary area. The pulse was rapid (136 per min.), full, and soft. Blood pressure 95–100 mm. Hg. Respiration was rapid (36 per min.) and shallow. There was a slight icteric tinge of the skin of the face and conjunctivæ, and considerable œdema of the back. Urine showed a faint trace of albumin, a few urinary epithelial cells, and one or two degenerated granular casts. Ten days after its receipt the wound was almost healed and the ecchymosis of the loin had disappeared, but gangrene of the left leg was complete and the leg was therefore amputated below the knee by Captain Le Mesurier, R.A.M.C. (T.C.).

The patient's condition improved for a short time, but in a few days the amputation stump became gangrenous. A booming cavernous note was detected in the aneurysmal murmur as though the aneurysm had enlarged, and the respiration, which had always been shallow and rapid, became gasping and very rapid, with a greatly increased pulse-rate. Finally the patient became delirious, the pulse was uncountable, and the respiration-rate rose to 60–70 per min. The temperature steadily rose and the patient gradually sank and died in coma, one month after the receipt of the wound.

Post-mortem Notes.

The peritoneal cavity was free from fluid, except for a small quantity of blood-stained exudate. In the extra-peritoneal tissue planes in the region of the left iliac fossa and left psoas muscle was a widespread ecchymosis extending into the pelvis and across to the right iliac fossa. There was a large fluctuating swelling commencing at the lower part of the left common iliac artery and vein. Its periphery was ill-defined. The abdominal aorta appeared contracted and rather shrunken, and the left common iliac artery was small. Both vessels contained a little recent clot. The inferior vena cava was large and dilated and full of dark fluid blood. The renal veins were large, and both common iliac veins were distended, especially the left. The left femoral artery was small, collapsed, and empty, but the femoral vein and internal saphenous vein were large and thrombosed. The aneurysm was ligatured above at the common iliac artery and vein, and below at the femoral artery and vein. On dissection it was found that the left external iliac artery communicated along its posterior aspect, immediately below the origin of the left internal iliac artery (Plate II., A), by a bevelled opening, with the anterior wall of a large saccular aneurysm about 4 inches long by $3\frac{1}{2}$ inches wide formed by the internal iliac vein. The external iliac vein lay in the anterior wall of the aneurysm, with a crescentic opening into the apex of the sac (Plate II., B). It was completely thrombosed below this opening. The external iliac artery was patent both above and below its opening into the sac (vide Plate II.).

The liver was enlarged, hard in parts, and showed a typical "nutmeg" appearance. The spleen was slightly enlarged, dark coloured, tough, and elastic. The kidneys showed congestion at the bases of the pyramids, but were free from marked changes. The pleural cavities contained a small quantity of blood-stained exudate, and the pericardial cavity contained a slight excess of clear fluid. The right lung showed some collapse at the base of the lower lobe and posterior border. There was a slight compensatory emphysema of the upper lobes. The left lung showed an infarct 4 inches from base of the lower lobe immediately below the inter-lobar fissure extending to the anterior border of the lung. The infarct was dark red, very hard and well defined, size 4½ inches by 1½ inches broad. The adjoining lung tissue was healthy. There was a smaller infarct 1¼ inches above the larger infarct near the anterior border of the lower lobe, which showed a moderate degree of collapse of the base and posterior border. There were a few small areas of collapse in the upper lobe. The heart was opened in situ while attached to the lungs in order to determine the cause of the infarcts. The veins of the chest and neck were engorged with blood, and the right ventricle when opened was slightly dilated, and contained a quantity of dark fluid blood. The tricuspid valve was normal in appearance. The pulmonary valve was intact and healthy, and the cusps normal. The right branch of the pulmonary artery was healthy and contained fluid blood. The left branch of the pulmonary artery presented no abnormalities, but on opening the branch running to the lower lobe of the left lung the scissor points grated on a metallic body. This was found to be the base of a rifle bullet which was very firmly wedged in the lumen of the vessel surrounded by a small quantity of fibrinous clot. The bullet was in perfect shape with its axis directed in the course of the vessel, and its apex wedged firmly into it, completely occluding its lumen, and by its lateral aspect blocking the opening of a smaller branch, thus causing the second infarct.

Weights of abdominal organs: Liver, 65 oz.; spleen, 10 oz.; right kidney, 4¼ oz.; left kidney, 6 oz. Weight of bullet, 10 g.; length, 2·8 cm.; circumference, 2·2 cm.; diameter of base, 0·7 cm.

Discussion.

From measurement in situ and standard measurements, the distance travelled by the bullet in the blood stream was not less than 2 feet (60 cm.). Since the blood pressure in the inferior vena cava in the normal condition stands at about + 3 mm. Hg and diminishes in the veins of the chest and right auricle to − 8 mm. Hg, while the velocity of the blood is not more than 25 cm. per second, it is probable that the blood pressure in the abdominal veins must have been greatly increased through the formation of the arterio-venous aneurysm, to have enabled the venous flow to sweep such a comparatively heavy weight as 10 g. along the veins. Raising of the venous blood pressure, no doubt, accounts for the continuously rapid pulse-rate, which never fell below 120 per minute, and for the rapid rate of respiration, 30–40 per minute, rising in the later stages to 60 per minute. The condition, in fact, was one in which the patient was bleeding into his venous circulation. This is supported by the comparatively low arterial blood pressure 95–100 mm. Hg and the full, soft, collapsing pulse. The raised venous blood pressure is evidently the cause both of the dilatation of the veins and of the rapid establishment of the condition of chronic passive venous congestion of the abdominal organs which was found post mortem.

Freedom of the blood stream from general infection and absence of suppuration at the site of impaction of the bullet were doubtless due to its uninjured and smooth surface. The absence of any pain at the site of the wound, the intense pain referred to the foot and leg, both at the time of receiving the wound and subsequently, combined with the complete absence of pain in the heart or lungs, are interesting features. Some anginal pain might have been expected during the passage of the bullet through the heart, though the diameters of the pulmonary and triscuspid orifices are sufficient for the transmsssion of the bullet even in its long axis. As shown by X ray the bullet had passed above the level of the umbilicus before admission of the patient to this hospital. Probably the smooth surface of the bullet and its "stream-line" shape helped to lodge it so aptly in the pulmonary artery.

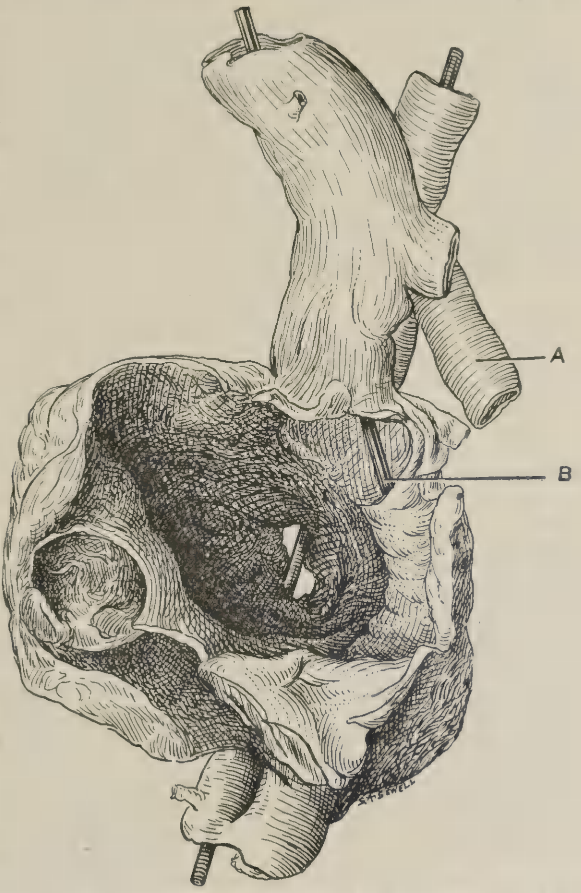

PLATE II.—Arterio-venous saccular aneurysm viewed from behind.

Summary.

The points of interest in this case may be summarised as follows:—

1. The distance and deflected course travelled by a rifle bullet in the blood stream.
2. The power of the right side of the heart to pump into, through and out from its chambers, a foreign body of this size without, moreover, any damage to its walls or valves.
3. The formation of two infarcts in the lower lobe of the left lung by the bullet acting as an embolus.

4. The absence of pain referred to the heart or lungs, the freedom from any syncopal attacks, and the absence of any infection of the blood stream.

5. The condition of marked passive venous congestion established in the short period of a month.

6. The length of time (one month) during which the patient lived with a bullet inside his circulatory system.

The specimen is exhibited in the War Museum at the Royal College of Surgeons (Catalogue number, W.O. 3071).

I am indebted to Lieutenant-Colonel S. G. Butler, D.S.O., R.A.M.C., for permission to use the notes of this case, to Colonel W. Pasteur, C.M.G., and Lieutenant-Colonel C. J. Martin, F.R.S., and Professor Arthur Keith, F.R.S., for their assistance and advice.

MALARIA AND INSANITY.

BY A. T. W. FORRESTER, M.D. LOND.,

MAJOR, R.A.M.C.; SENIOR ASSISTANT MEDICAL OFFICER, LEICESTER COUNTY ASYLUM.

IN Macedonia malaria was reckoned as far and away the biggest factor in the causation of mental disease amongst our troops. Indeed, the admission-rate of the latter is almost an exact parallel of the malaria curve. The following notes were made of cases which comprise all those arising in the British Salonika Force (and subsequently in the army of the Black Sea), which were eventually admitted into the mental department from a period December, 1918, until October, 1919.

I have only included cases giving a positive history of malaria, whether or no this was the causative factor in the production of mental symptoms, and have endeavoured to arrive at a few conclusions about the psychoses caused by, or arising in, this protean infection. Both the benign and malignant tertian varieties occur, the latter predominating in the autumn months. Except in the causation of cerebral malaria, let it be said at once that no distinction could be drawn between the two for the purposes of this paper.

It appears to me that no new train of symptoms is set up by malaria, and that in comparison with any other acute specific fever it differs only in intensity and in the more selective action of its toxins on nerve tissue. The brunt of the attack falling on the cortical higher centres, we may get the train of symptoms of acute confusion of a cerebral type—the type of mental disorder which occurs very, if not most, commonly. To show a finer differentiation in its choice of nerve cell, I have seen four cases of single nerve paralysis due to malaria, two involving the sub-trapezial plexus alone, others the third and seventh cranial nerves. A heavy and more general segregation of parasites in the brain may give rise to the well-defined cerebral malaria.

Altogether during the above period there were 116 admissions to the mental department giving a positive malarial history. Both on the physical and mental sides they fall more or less into two groups of case: (I.) Those associated with the actual malarial attack itself; (II.) those occurring as a result of repeated attacks. The former are always the more acute and more approximating to a severe delirium. Other things being equal, the prognosis is better, and as a rule they yield easily and rapidly to appropriate treatment.

I. *Mental Symptoms in Association with an Actual Attack of Malaria.*

These comprise 32 cases, of which 9 were primary infections, the remainder occurring during a relapse. They showed that almost any of the recognised types of psychosis can be set up by the malarial parasite, but one symptom stands out prominently amongst them—namely, mental confusion. It was present in 22 cases, or 68·75 per cent. Next in order of frequency was depression, with 12 cases, giving a percentage occurrence of 37·5. Two cases of this group turned out to be cerebral malaria.

The degree of confusion may vary from what may be described as a severe delirium such as occurs in any pyrexia, to a complete dissociation of personality, the latter giving beautiful and typical examples of the occurrence of a definite fugue. These are so important that I will digress for a moment. They include in number 9 cases, while exactly the same number occurred in Group II., or apart from a definite rigor. But here comes out the value of the soil, as of this latter group, 2 were slightly feeble-minded, 2 gave a definite insane heredity, 1 had had St. Vitus's dance when young, and 1 gave a history of a similar attack previous to the malarial infection. In nearly every case some breach of military discipline had been committed, usually a court martial offence, and they were in consequence admitted to the department as prisoners. The commonest charge was, "Absent without leave," other crimes being self-inflicted wounds or destroying Government property In every case there was complete amnesia for the whole period, the shortest of which was a few hours, and the longest three months. One man had been convicted and punished for three similar happenings before his case was recognised, and he was sent down to the base for observation. This serious complication occurred so frequently, as compared with its incidence apart from malaria, that it seems as if this disease must be reckoned as an actual determining cause.

Two cases of acute delirium were started by the malarial attack. One of them is noteworthy owing to subsequent complications. He developed broncho-pneumonia in both lungs and finally meningitis, a pure culture of the pneumococcus being grown from the cerebro-spinal fluid. Eventually this man made an excellent recovery and was able to be invalided home as an ordinary medical case. With confusional insanity no memory of the acute illness was retained.

It has been noted that two cases of cerebral malaria were admitted. Diagnosis here rests on obtaining a positive blood-film. I have seen this very dangerous condition give a picture of cerebral hæmorrhage, of just drowsiness or simple delirium, of violent excitement and violence, or of epileptiform attacks. It was a condition we had always to be on the look-out for, especially during the autumn months, and it demands immediate and energetic quinine treatment by the intravenous method.

Lastly, in the cases of this group heredity played a very unimportant part, as a history of insanity was only traceable in 2 cases. Hereditary suicide was also given in 2, both of whom actually attempted their lives, thus bearing out the usual teaching on this point.

II. *Mental Symptoms as the Result of Repeated Attacks.*

Of the second class of case, 87 in number, alcohol was the cause of the mental disturbance in 7, while 9 suffered from varying degrees of feeble-mindedness. The latter were usually sent down in consequence of frequent entries on their conduct-sheets, punishment having no deterrent effect. In most cases they should never have been accepted for military service. One case was returned "Not insane." In the remaining 70, in which malaria was the determining factor, it was again found that any type of psychosis may be set up. But the prominent symptom is still mental confusion; and almost equally important is now that depression which one would expect to come on as a result of prolonged stress and toxæmia. These, most of them, had been conscious for some time previous to the actual breakdown of a failing in physical and mental vigour. After repeated malarial attacks, prolonged residence in a hot and unhealthy climate, with indifferent food and continual disappointment in the matter of leave, and sometimes bad news from home, it was no wonder that mind as well as body gave way. But heredity here comes in prominently as a factor. Of the 24 cases in which a diagnosis of depression is given an insane heredity was traced in 9; while in 31 cases of confusion 7 showed an insane heredity. In some of them this confusion cleared up in a day or two, others convalescing more slowly.

The onset of well-marked dementia præcox was determined in eight cases. The kind of disorder is shown in the following table, and except for particulars already mentioned they followed out more or less the usual experience in these cases.

Mental confusion	with a definite fugue ...	9	31
	simple	22	
Depression...			24
Dementia præcox			8
Delusional insanity			6
Excitement with violence			1
Total			70

Now, where it is a case of chronic malarial poisoning there is always involvement not only of the cells of the higher centres, but the whole central nervous system shares in the attack. The sympathetic and vagus are affected, giving rise to abnormalities of pulse, tachycardia, palpitation, shortness of breath on exertion. There are frequently cardiac murmurs present, and marked coldness or even cyanosis of fingers and toes. Superficial and deep reflexes are always altered and generally markedly exaggerated. Knee and ankle clonus occur, and I have seen nystagmoid movements of the eyes. There is always a marked anæmia and debility, sometimes a profound cachexia. Spleen and liver are enlarged, and there is, of course, wasting and emaciation.

Prognosis and Treatment.

Unless other causes are at work the prognosis is always good, and is concomitant with improvement in health. Unfortunately, the malarial parasite, especially the benign tertian variety, is extremely resistant even to prolonged and energetic quinine therapy. But as soon as this was instituted, despite the tendency to relapse about the tenth day, patients at once began to mend. With cachectic conditions large doses of quinine are not readily tolerated by the stomach, and by upsetting digestion mitigate against the equally important assimilation of food. Intramuscular administration is of undoubted benefit under these conditions, and I have seen rapid improvement follow this when combined with intravenous galyl. Cacodylate of soda proved disappointing in my hands. And even though one was also frequently disappointed by the reappearance of malarial attacks soon after a course of intramuscular quinine injections, yet these patients always gained considerably in weight and improved in condition. On these grounds alone the course was justified, and in competent hands the method is practically free from risk of complications. The importance of correct and appropriate treatment is a point that is brought out most prominently. It was quite common to be given a history of frequent relapses treated casually with occasional doses of quinine, and no attempt made to control the attacks. Although it is true that the mortality from this disease is extremely low, it must be borne in mind that a potent and powerful poison is circulating all the time, which may flare up at any moment into an acute condition such as cerebral malaria, or result in permanent damage to mind and body.

All cases of malarial psychosis should be removed at once from danger of reinfection. This, with us, was the slowest of processes, and the waiting list of men marked "Hospital Ship" somewhat resembled that of any popular motor-car manufacturer at the present moment. It would be interesting to trace the subsequent history of one's cases, but this proves almost impossible in practice.

Prophylaxis.

I should say that the majority of the cases in Group II. might have been prevented had the true meaning of the danger signals which they had been showing for some time previous to admission been realised. The spirit of "Carry on" does not always lead to the happiest results, at any rate for the individual. But I had men sent for admission in whom the watchful eye of the regimental medical officer had spotted incipient signs. One can say definitely that these cases were saved from proceeding to a well-defined psychosis, and were quickly ready to be evacuated as ordinary medical cases, by this means being saved the undoubted stigma which the word "mental" carries.

As regards malaria itself, I think the theory of quinine prophylaxis has been definitely exploded. Keep up body resistance by good feeding and ordinary hygiene, and place no reliance on drugs.

Dealing with mental cases in the prodromal period, it was interesting and instructive to be able to watch the lines along which definite insane ideas seem to crystallise out. Most of us feel that in preventive medicine lies the future of our science. This, as applicable to mental disorders, is just as hopeful as in any other branch.

One looks forward to the time when mental hospitals, properly equipped, will be set up and run along modern lines, with skilled nursing and the advice of specialists in every branch of our science coördinated, where the atmosphere is one of recovery and not chronicity, and where patients will themselves voluntarily come early for advice, if not for admission. But for this to accrue such a hospital must be removed as far as possible from the word "lunacy." Asylums will unfortunately always be necessary for a certain proportion of cases, but an acute recoverable patient should never see the inside of one of these institutions.

THE BONE DEFORMITIES OF RENAL DWARFISM.

BY HUGH BARBER, M.D. LOND.,
PHYSICIAN TO THE DERBYSHIRE ROYAL INFIRMARY.

IN the last few years a number of cases of interstitial nephritis in children associated with stunted growth have been recorded, some of them with infantilism in all its characteristics, others merely with a marked degree of dwarfism. Until some standard text-book gives a full account of this condition it is not easy to select a suitable name; but as the kidney disease not infrequently has a very insidious onset, and many of the cases seek advice for the first time for want of development or bone deformity, some name such as renal dwarfism may be used. There have been several cases recorded in which an operation has been performed for genu valgum and the patient has died shortly afterwards. Three cases of this disease were recorded from the Derbyshire Royal Infirmary in 1913,[1] and a fourth in 1918,[2] all proved post mortem; but the three cases in this paper demonstrate the insidious nature of the disease and the deformities so well that a further note on the subject may be justified.

Interstitial nephritis in children is usually a somewhat insidious disease, characterised by stunted growth, an unhealthy pallor of the face, urine of low specific gravity, varying from 1010 to 1004, and the presence of albuminuria, small in amount and not always present constantly. But a severe case may show a degree of polyuria and thirst equal to that met with in diabetes insipidus. The cardiovascular changes are slight, it is not easy to demonstrate thickening of the arteries, hæmomanometer readings are not high, and there is little hypertrophy of the left ventricle. Deformities of the bones, very similar to those of rickets, are frequently present by the time the patient approaches the age of puberty. Dwarfism, amounting to true infantilism in some cases, is a marked feature. In the eight cases that have been under my observation development has been fairly normal until the age of 5 or 6 years, after which growth has been very much retarded. The usual age of onset is hard to determine on account of the insidious nature of the symptoms. The fatal cases have died of uræmia without much warning, most commonly about 16 years of age, and probably no case reaches adult life. Post mortem the kidneys are small, the capsule strips easily, the cortex is shrunken, and microscopically there is interstitial nephritis. The ætiology is obscure and the history of any antecedent infectious disease is not a feature. In one or two recorded cases the Wassermann test has been positive; there have been no evidences of congenital syphilis in the cases I have seen and only one positive Wassermann result out of six cases tested.

Deformities Discussed in Detail.

To discuss the deformities in detail:—

(1) *Frequency of occurrence.*—Out of the eight cases five have shown bone deformity, but this does not enable one to discuss the percentage, because four of these five first sought advice for genu valgum; the signs and symptoms of kidney disease are more or less latent, and there may be cases of interstitial nephritis which are never diagnosed at all.

(2) *Age of onset.*—The deformities appear to develop about the time of puberty. I have a very definite history on this point in four cases, and the fifth (Case 1 in this paper) was diagnosed at 12½ years as interstitial nephritis with dwarfism, without bone deformity, and returned on account of recently developed deformities when aged 16 years.

(3) The *genu valgum* appears to develop comparatively quickly, straight legs becoming markedly deformed in a few weeks.

(4) In *type* the changes seem to be very similar to those of rickets; the wrists and knee-joints have been most noticeably affected, but some swelling has been palpable at the junctions of the ribs and costal cartilages.

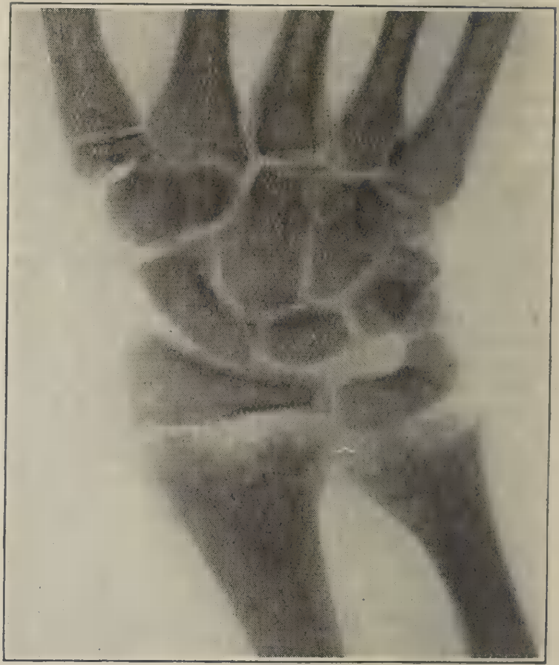

FIG. 1.—Radiogram of the wrist in a case of renal dwarfism, showing zones of proliferation at the epiphyseal lines and irregular calcification. (Case 1.)

(5) *X ray notes* by Major A. E. Milner (see Fig. 1): The changes are most marked at the wrists and knee-joints; there is increase in the size of the proliferation zones, the normal translucent line is greatly increased in breadth, there is not only enlargement, but great irregularity and want of definition due to irregular calcification.

Notes of the Cases.

CASE 1.—W. M., aged 12½ years. First attended in January, 1915, for thirst and polyuria; height, 4 ft. ½ in.; heart and arteries normal, hæmomanometer reading 100 mm.; urine, sp. gr. 1006, albumin present 1 part per 1000, total quantity 41 oz. in 24 hours. He was under observation for three months, and there is a note that no deformities were present. He has had no infectious disease. His next attendance was 3½ years later, aged 16 years, for deformity of the legs. He gave as history that he was at work until he had influenza three months previously, that he was in bed four weeks, and that when he got up his legs were crooked. (See Fig. 2.) On examination: height 4 ft. 4 in. (ten inches below the average), knees and wrists swollen (Fig. 1), legs deformed as in photograph; urine as before. Wassermann negative. Family history: Father alive and well; mother died of chest trouble; one sister, who died of pneumonia; two brothers, the elder a sailor and the younger also healthy.

CASE 2.—M. W., aged $13\frac{3}{4}$ years. Has always been small, walked when two years old, development has been poor since about six years of age, has suffered from thirst all her life, has never had scarlet fever or any other serious illness. She attended medical out-patient department when aged 6 years for blue hands and feeble action of the heart; the urine was not examined. About Christmas, 1918, the legs became crooked, when child was aged 13 years. Admitted September, 1919, for genu valgum and dwarfism; height 3 ft. 9 in. (ten inches below the average), legs deformed (see Fig. 3), knees and wrists swollen, slight beading of the ribs; urine, sp. gr. 1004, albumin a trace (tested on 30 occasions, absent twice), total quantity in 24 hours about 40 oz.; heart and arteries normal; hæmomanometer reading 90 mm., Wassermann positive (tested twice). X ray photos of bones similar to Case 1. Family history: Father and mother healthy, one of seven children, the first two died soon after birth, patient is the third, the others are healthy.

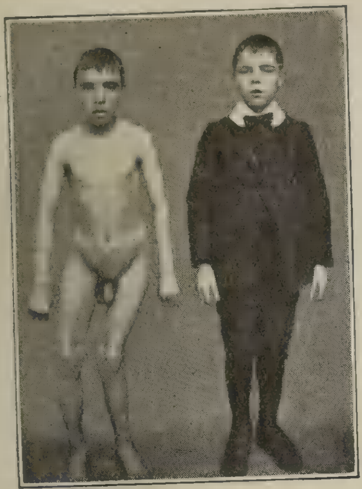

FIG. 2.—Case 1, aged $16\frac{1}{2}$ years; brother, aged 12 years.

Note.—Case 2 has since died of uræmia; the kidneys were very small and fibrotic, weighing 220 gr. each; microscopically well-marked interstitial nephritis.

CASE 3.—Girl, aged 13 years. Admitted September, 1919, to the surgical side for genu valgum, which had developed 16 months previously. On examination height 4 ft. 4 in. (three inches below the average), pubic hair present; urine, sp. gr. 1008, albumin present, one part per 1000 (examined on 22 occasions, absent twice), total quantity about 50 oz. No cardiovascular changes; hæmomanometer reading 100 mm. Wassermann negative. Ten years ago she was in this institution diagnosed as diabetes insipidus; urine, sp. gr. 1008 to 1010, albumin not found. She contracted scarlet fever and was transferred to the isolation hospital. The mother says she has always been thirsty and the legs weak, but was otherwise well; had had an attack of measles. Family history: Father and mother healthy, one healthy brother, one brother died of heart disease.

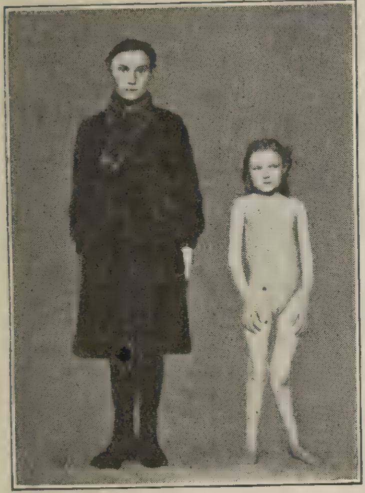

FIG. 3.—Case 2, aged 13 years; sister, aged 11 years.

Facts Showing the Insidious Nature of the Disease.

The following facts, which appear in the notes of the cases, may be selected to emphasise the insidious nature of the disease.

(*a*) Case 1 was diagnosed at my out-patient department, aged $12\frac{1}{2}$ years, with straight legs; he attended for a month or two and returned three and a half years later on account of recently developed genu valgum.

(*b*) Case 2 attended as an out-patient under one of my late colleagues seven years ago for "weak action of the heart" and blue hands; urine not examined.

(*c*) Case 3 was admitted to this institution ten years ago, diagnosed as diabetes insipidus, with urine of low specific gravity free from albumin. She was sent up this time as a surgical case of genu valgum.

AN IMPROVED TECHNIQUE FOR THE STAINING OF SPUTUM FOR TUBERCLE BACILLI.

BY A. DISTASO, D.SC.

THE routine examination of sputa for tubercle bacilli conducted on any large number of specimens precludes the use of the many methods of concentration, of which the antiform method is probably the best. The errors inherent in the ordinary spread slide method are numerous, and no doubt account for the unsatisfactory results obtained. The method here outlined overcomes some of the difficulties and raises the percentage of positive results by at least 25 per cent., besides affording a film which is restful to the eye and easy of manipulation. It takes less time in execution than the ordinary method. The method allows for twice the usual amount of sputum, secures the easy solution of the tough muco-purulent pellets, and gives an even film and a very transparent counterstain.

A thick portion of the sputum or several muco-purulent pellets are selected and transferred to the slide. One drop of 5 per cent. NaOH is added and the sputum emulsified, with the aid of heat, into a transparent gelatinous mass, which is spread evenly and set to dry in the incubator. When perfectly dry it is immersed in fuchsin, warmed to incubator temperature, and allowed to remain in the incubator for 15 minutes. It is then washed in equal parts of Esbach solution and water, decolorised with 25 per cent. nitric acid until faintly pink, and then washed in water, in 60 per cent. alcohol, and then again in water. The counterstain used is malachite-green (1 part of saturated alcoholic solution in 19 parts of water) for 30 seconds to one minute, and the slide is rinsed and dried.

Six thousand sputa have been examined both by the routine method and by this method, in which positive films show two to three times the number of bacilli. In my statistics the ordinary method yielded one positive film in four, in the new method one positive in three. Malachite-green gives a soft pleasing ground-work in strong contrast to the bacilli and materially lessens the labour of the search. Large numbers of slides can be manipulated in mass.

University College, Cardiff.

RESECTION OF THE RECTUM FOR CANCER.

BY P. LOCKHART-MUMMERY, F.R.C.S. ENG.,
SENIOR SURGEON TO ST. MARK'S HOSPITAL FOR DISEASES OF THE RECTUM, AND TO THE QUEEN'S HOSPITAL FOR CHILDREN, ETC.

(*With Illustrative Plates.*)

HITHERTO operations for the removal of the rectum for cancer have compared unfavourably with such operations as removal of the breast, &c., chiefly because they have been accompanied by a high mortality, or because they were only possible in a small proportion of the cases seeking treatment. The dangers of the operation have been mainly two—shock following a long and serious operation in an elderly patient, and sepsis.

The technique of the operation here described has been slowly evolved, and it has the advantage of overcoming to a large extent both these difficulties. I have for some years been trying to find a technique which would enable me to remove the rectum for cancer with a reasonable degree of safety and without the serious mortality which has hitherto accompanied rectal excision, and which would be applicable to all cases where the growth had not already invaded vital organs or set up metastatic deposits. The fact that in 1918, the fourth year in which I had used this technique as a routine method for growths of the rectum, the mortality was nil, although the largest number of operations were performed in this year (24), has encouraged me to think that the details of this operation are worth publishing.

Mortality and Causes of Death.

During the last four years I have used this technique in removing the rectum for cancer in 65 cases, of which 37 operations were performed in hospital and 28 cases in private. Five deaths occurred among the hospital cases, and no deaths among the 28 private cases. The most satisfactory feature, however, is that during 1918, when I and my assistants had had more experience with the technique, the mortality in the 24 cases operated upon during the year by this method was nil.

Year.	Number of cases operated on.	Number of deaths.
1915	8	1
1916	16	2
1917	17	2
1918	24	0
Total	65	5

The mortality from operation during the four years covered by the figures accompanying this paper is higher than it should be, as two of the deaths were exceptional and not attributable to the operation. Thus one patient died from hæmophilia and one died suddenly from cerebral embolism 13 days after the operation. In the former case the patient had come all the way from South Africa on purpose to have the operation, and was known to be a congenital hæmophiliac. He fully understood the special nature of the risk he ran, but wished to have the operation performed. The pathologist was called in, and three weeks were spent in getting his blood coagulation-time up to the normal before attempting the operation. In spite of this, however, the typical bleeding occurred, and proved fatal ten days after the operation. Of the other three deaths two were due to sepsis and one to hæmorrhage.

Advantages of Method of Operation Used.

The technique of the operation described here makes it possible to perform an absolutely aseptic operation from start to finish, and so abolish the chief cause of mortality—namely, sepsis in some form or another. Owing to the fact that the removal of the rectum of necessity leaves a large cavity, which cannot be filled up except by blood clot, primary union only occasionally occurs. More commonly there is a small cavity which heals by granulation in the course of three or four weeks. Convalescence, however, should run an aseptic course with a normal temperature. In some cases primary union has been obtained, and the wound has remained perfectly dry after the third day. Such cases have generally been women in whom the pelvic organs readily fall backwards and fill up the cavity left by the removal of the rectum.

The other great improvement in the technique has been the method of anæsthesia. It was recognised that two things must be aimed at—complete protection from shock in any form, and absence of vomiting after operation. Vomiting is particularly undesirable after excision of the rectum because it tends to break down the new peritoneal floor of the pelvis and produce a hernia in the wound, and it also tends to set up secondary hæmorrhage. The necessary conditions have been attained by using gas and oxygen, or twilight sleep, combined with spinal or local anæsthesia. No other anæsthetic at all is used. When spinal anæsthesia is used great care is taken to see that the patient is kept with the head slightly down from the time that the anæsthesia begins until all sensation in the legs has returned. This is, I believe, most important in protecting the patient against the effects of gravity during the time that a large part of his vasomotor system is paralysed. As a result of this precaution there has been only one case of slight headache in all the cases and no other after-effects. Local anæsthesia gives equally good results, but is more troublesome.

One very marked advantage of this technique is that it has rendered it possible successfully to excise the rectum of patients in whom operation by any other method would have entailed impossible risks. I have not hesitated in the last three years to perform excision in patients as old as 73, provided other factors were favourable, and also in cases where other serious disease was present; and so far my confidence has been justified in that all the patients have pulled through without mishap. There were 20 patients over 60 years of age and 4 over 70. Two patients had bad chronic bronchitis, one had albuminuria, one old-standing locomotor ataxia, one bad Graves's disease with a pulse of 130. All these patients came through without complication.

It has long been my view that no operation for cancer of the rectum can be considered satisfactory unless it can be used with a reasonable degree of safety in cases where the patient is a bad subject, as the majority of patients suffering from cancer of the rectum are necessarily bad subjects owing to fat, age, or complicating disease. An operative technique which requires that the patient shall be a first-class subject will either be accompanied by an appalling mortality or will only be available for a small percentage of the cases requiring treatment.

This operation is suitable in any case where the growth is at the anus or anywhere in the rectum proper, provided that it is not fixed to important structures. It cannot be performed if the growth

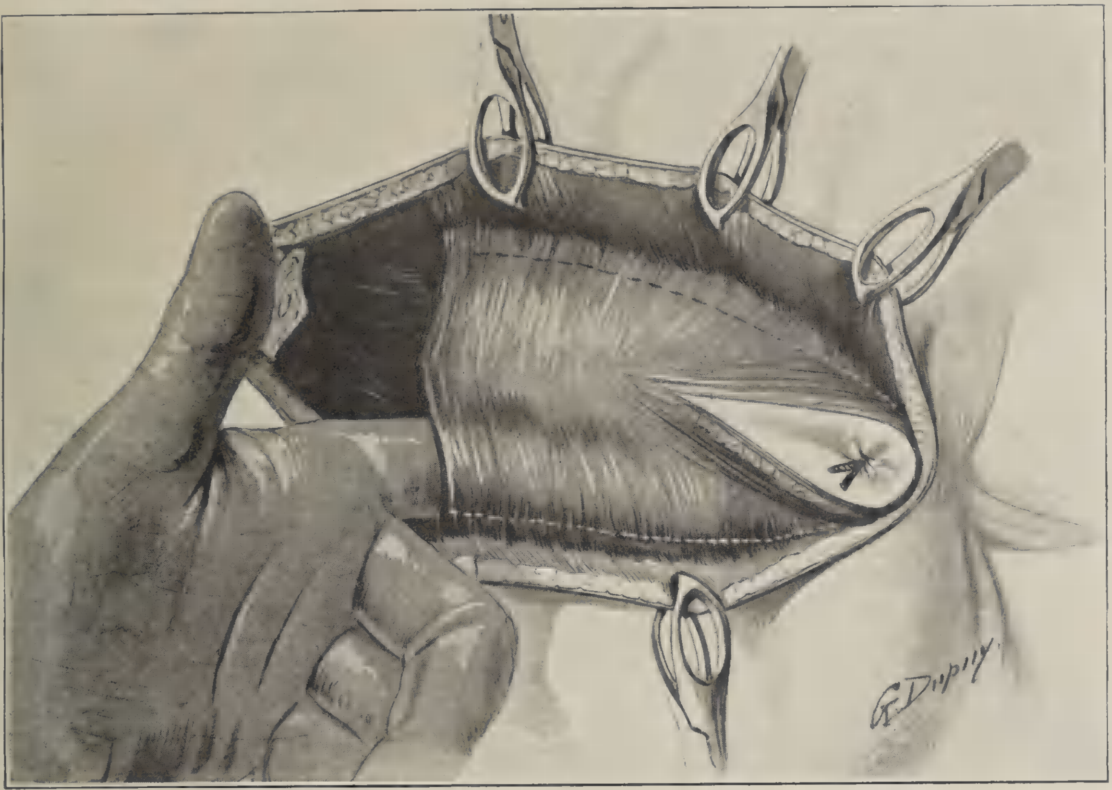

PLATE I.—Showing the method of dividing the fascia and levator ani muscle where it is reflected from the pelvic wall on to the rectum. The first finger is passed deep to the muscle and the division made with scissors along the dotted line, the lower side being cut first. Previous to this the fascia is cut through transversely as shown.

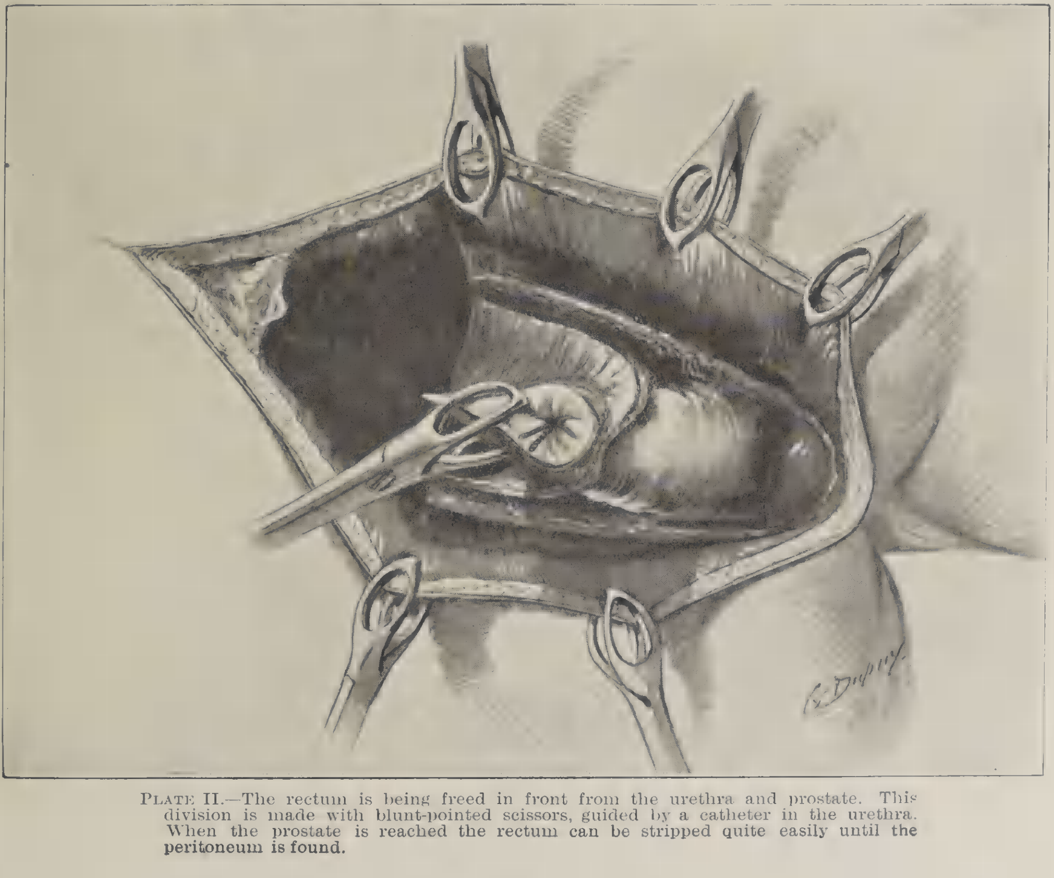

PLATE II.—The rectum is being freed in front from the urethra and prostate. This division is made with blunt-pointed scissors, guided by a catheter in the urethra. When the prostate is reached the rectum can be stripped quite easily until the peritoneum is found.

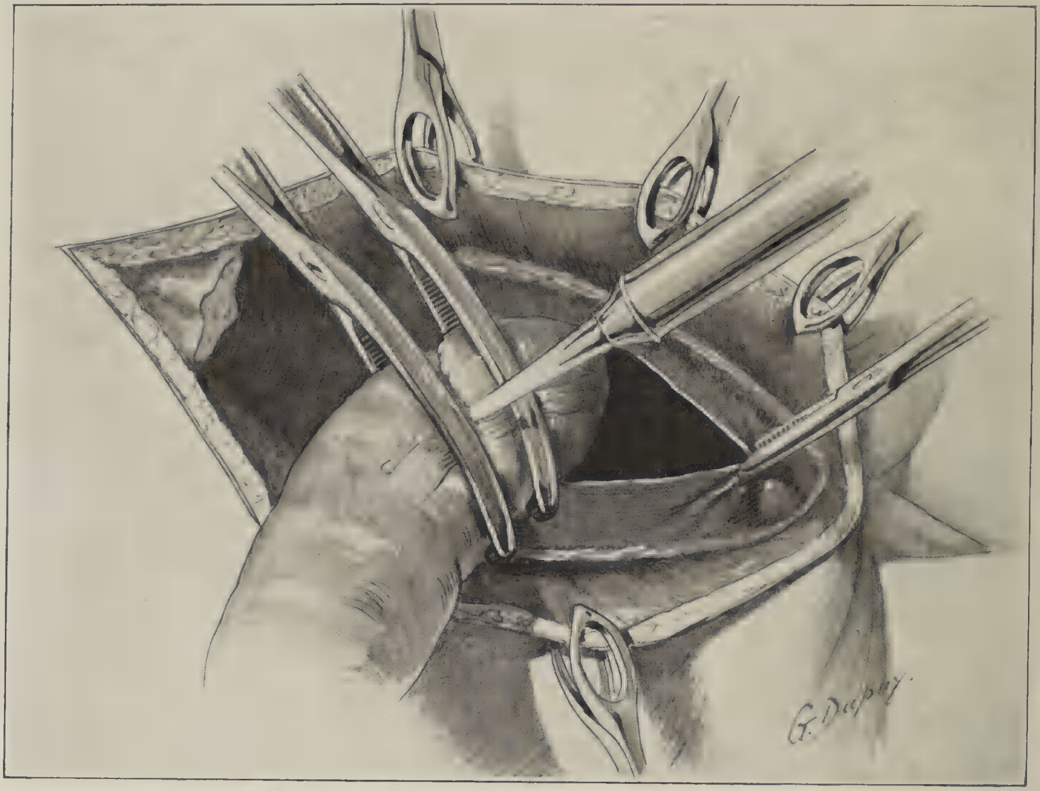

PLATE III.—The rectum has been freed and the peritoneal cavity opened. The meso-rectum has been tied off. Two clamps have been applied to the sigmoid and the bowel is being divided between them with a cautery. The peritoneal cavity is shown open; in reality it would be packed off with gauze tampons, as would the whole wound.

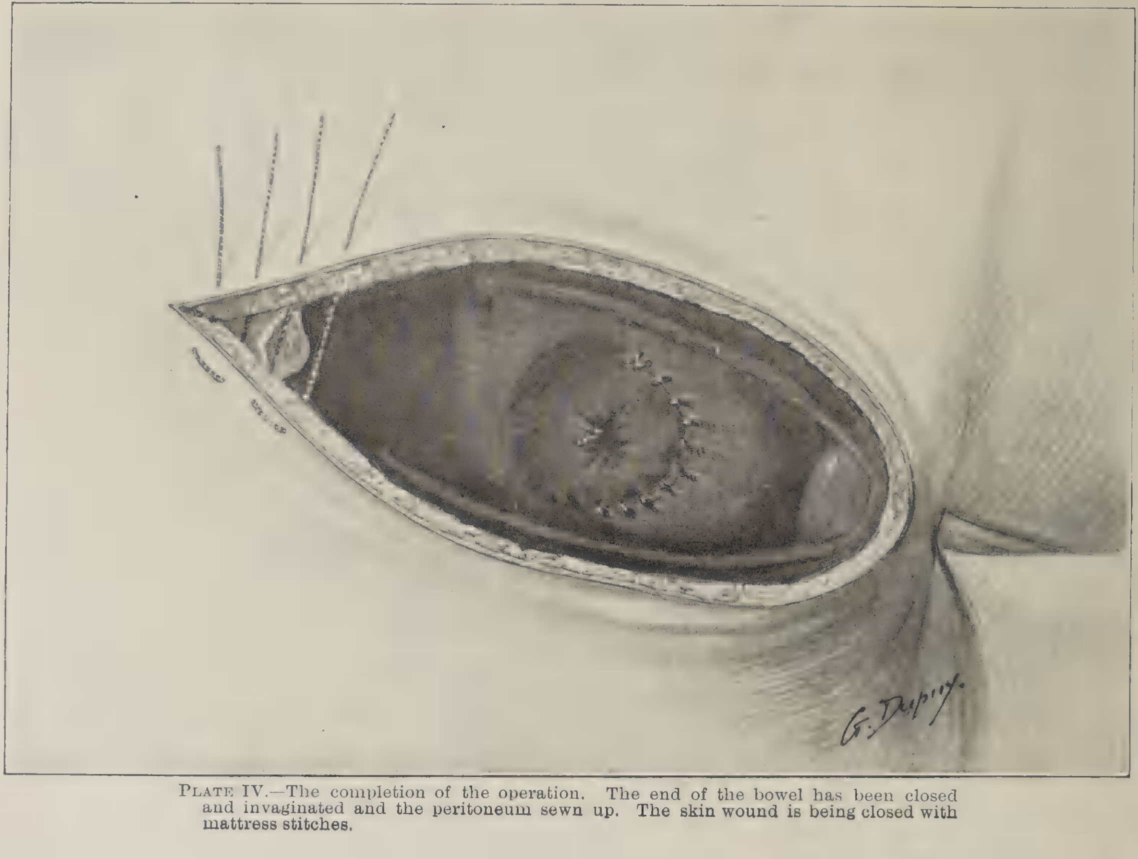

PLATE IV.—The completion of the operation. The end of the bowel has been closed and invaginated and the peritoneum sewn up. The skin wound is being closed with mattress stitches.

is at or above the recto-sigmoidal junction unless the growth is small and the sigmoid fairly lengthy.

Description of Operation.

The operation is performed in two stages as a rule, but this is not essential unless the patient is old or unless some degree of obstruction is present. The first operation consists of a colotomy performed through the left rectus, fairly high up; this is done under gas and oxygen and local anæsthesia. At the same time the opportunity is taken of examining the abdomen for secondary deposits and, if necessary, the upper limits of the growth for adhesions to the bladder, &c. The colotomy is opened two days later, and the lower bowel and rectum are then washed out daily from the lower colotomy opening. In cases where the growth is small and situated near the anus it is often possible to leave the patient with a sacral anus if there is any special reason for doing so.

The second operation is performed a week or ten days later. The patient is not starved beforehand; he is only deprived of breakfast on the morning of operation. Heroin or morphia and atropine are given about three-quarters of an hour before operation unless "twilight sleep" is being used, when scopolamine and morphia are substituted. The operation is performed in the left semi-prone position. Before beginning the operation a No. 8 gum elastic catheter is tied into the bladder, if the patient is a man, in order to act as a guide to the urethra during the operation. The first step in the operation is to pass a stout silk ligature round the anus subcutaneously with a curved needle. This is tied up tightly so as to exclude the anus entirely. After this the skin all round is thoroughly painted with iodine and the towels are put in place. The surgeon does not wash up or put on his gloves till after he has closed the anus. The incision is made starting from the base of the sacrum and carried forwards in the mid-line surrounding the anus, and well clear of it to meet about 1½ inches in front. This incision is then deepened, cutting well away from the rectum into the fat. The coccyx is disarticulated, or, in case this should not give room enough, some of the sacrum is removed. The deep fascia is opened just in front of the sacrum, and the first finger of the left hand is passed deep to the left levator ani muscle, and the latter cut well away from the rectum with scissors. The same is then done on the right side. The next step is to dissect the rectum away from the prostate or vagina in front. This is easy in the female, but rather difficult in the male. The catheter tied into the urethra is a useful help, as it can be felt through the wound, and prevents one from getting in front of the prostate. This part of the dissection must be done boldly with scissors, care being taken not to injure the rectum, as this would involve a septic wound. After the wound in front of the anus has been deepened about 2 inches the lower edge of the prostate will be reached, and the rectum will strip easily. The peritoneum will now come into view and should be opened and cut back along the sides of the rectum. The rectum and growth are now free except above. The mesorectum is now cut through as high up as possible, and the vessels in it caught with forceps and tied off. Only the bowel now remains to be divided. This is done between two clamps with a Paquelin cautery. The stump of the sigmoid in the upper clamp is now invaginated by a catgut Mickulicz stitch, and further protected by a mattress stitch outside this. The peritoneum is next closed by a continuous catgut stitch. The wound is then closed except for a single drainage-tube at the lower angle. Lately I have discarded the drainage-tube entirely. The operation has sometimes been performed in 35 minutes, and unless special difficulties are encountered it should not take more than 45 minutes. If in a female the posterior vaginal wall is involved it may be removed together with the rectum. In several cases I have removed the whole posterior vaginal wall, and in one or two cases the greater part of the prostate; in one case also a large portion of the posterior wall of the bladder.

After-treatment.

The patient is generally out of bed in 14 days, and usually able to return home in three weeks. There is one factor in the after-treatment which is a departure from common practice—namely, that ordinary solid food is given from the start. No alteration in the patient's usual diet is made, and he is given an ordinary meal as soon as he wants it. Beef-tea and milk are strictly forbidden. To ensure asepsis of the wound 1–20 carbolic dressings are used and changed twice daily.

Question of Recurrence of the Growth.

It is obvious that these cases are too recent to afford any useful guide, but my impression to date is that the results are quite good on this count.

The Degree of Disability.

This is very important, and difficult to gauge accurately. The resulting disability is almost entirely due to the colostomy opening. It is undoubtedly much less than in cases where a sacral anus has been left, as there is no trouble from prolapse of mucous membrane with a modern colostomy opening.

Out of 17 hospital cases in whom it was possible to investigate the disability from a wage-earning point of view, it was found that 12 had returned to work within a year of operation; 4 had not, and 1 had been obliged to take a lighter job. Those returning to work included persons in the following occupations: engine-driver on the railway, actor, washerwoman, workshop foreman, drapery assistant, munition worker, physical drill instructor, and stevedore. The disability would appear to be surprisingly little.

Summary.

The chief points in the operation are:—

1. The anus is sealed up before the operating field is prepared, and at no stage of the operation is the bowel mucosa exposed.
2. The freeing of the rectum in front is done from the perineum upwards; the only guide during this dissection in the male is a catheter in the urethra. Once the prostate is reached the dissection is easy, but care must be taken not to open the rectum.
3. The peritoneum is opened from the front of the rectum when reached.
4. The bowel is divided with the cautery between clamps, and the end invaginated.
5. The wound is closed, and the drainage-tube, if used, is removed in 36 hours.

As regards the blind portion of bowel below the colotomy opening, I have never seen any trouble result from it beyond a sinus which in a few cases persisted for some months. I have two cases in which this operation was performed over seven years ago, and neither of these patients suffers any inconvenience from the blind portion of bowel.

DIRECT INFECTION IN TUBERCULOSIS.

BY E. WARD, M.D. CAMB., F.R.C.S. ENG.,
TUBERCULOSIS OFFICER, SOUTH DEVON.

THE large number of possible sources of infection make it difficult to estimate the frequency of direct (patient to patient) infection in tuberculosis, but the existence of the difficulty is no reason why an attempt should not be made. The question can best be studied in rural or semi-rural districts, such as South Devon mainly presents. Moreover, the work of tuberculosis officer in South Devon is carried out entirely in the *homes* of the patients, thus affording far better opportunities for such observations than any work done solely at dispensaries, sanatoriums, or hospitals. As an illustration may be cited the case of a girl, aged 20, living in an isolated farm, who developed acute tuberculosis and died within three months of the onset. Taking a history in the usual way, there did not seem to be any likelihood that she had been in contact with another case of tuberculosis, but on examining, among others, a brother, who seemed breathless, and an aunt staying in the house, who had a cough, both showed physical signs of pulmonary tuberculosis. The aunt's sputum contained tubercle bacilli; the brother refused to send his sputum away for fear the result might interfere with his dairy work. Apart from a home examination these two cases would never have been discovered.

Method of Investigation.

In considering the probable origin of each case four headings have been used.

I. Immediate infection.—This corresponds to "direct" infection, as the term is generally used, and is here applied to cases known to have been in intimate contact with a source of infection within a short time of the development of their first symptoms. For example, a woman with advanced tuberculosis stayed at a farm on the moor from February to July, when she died. A child of 13, one of a family of five occupying the house, began to be ill in May, and in August was laid up with a large pleural effusion, apparently of tuberculous origin. This is classed as *immediate infection*. The word immediate is used to differentiate this class from the next.

II. Remote infection, in which the patient has been known to be in intimate contact with an infective case, either in early life or at some time separated by an interval of years from the appearance of the first symptoms.

III. No traceable infection.—This explains itself.

IV. Doubtful.—These are cases in which the evidence of immediate or remote infection is not sufficiently clear to bring them under these headings, while yet the probabilities of a direct infection are too great for them to be classed under III.

The history of all these cases was taken before the idea of the present paper had occurred to me, so that the results are not coloured by any preconception. The control cases were those seen for the sake of an opinion or after notification, but which were diagnosed as non-tuberculous either at the first visit or later. The history of these was taken in exactly the same way as the rest, and before a diagnosis was made.

Results.

In a first series of 252 cases of all ages and both sexes 102 were found to arise from immediate infection, 47 from remote infection; in 78 there was no traceable infection, and 25 were classed as doubtful.

An entirely new series was then started, this time excluding all patients under 16. This gave, out of 316 adults, 140 due to immediate infection, 44 remote, 112 no traceable infection, and 20 doubtful. Among 96 children under 16 we found 71 cases of immediate infection, 2 of remote, 22 no traceable infection, and 1 doubtful. Out of 102 non-tuberculous control cases, investigated in the same way as if they had been tuberculous, 5 could be classed as cases of immediate infection, 7 as remote; in 84 there was no traceable infection, and 6 were doubtful.

There has been no selection of any kind for these series. Surgical tuberculosis, of which there were a number of cases among the children, is included, also invalided soldiers who, as would be expected, considerably increase the numbers of no traceable infections. For instance, out of 77 tuberculous invalided soldiers there were only 4 cases of immediate infection, 20 of remote infection, 51 no traceable infection, and 2 doubtful.

There are also included various birds of passage, visitors, in whose case a history of direct infection was harder to trace, and a few better-class patients who likewise swell the numbers of the no traceables. Unfortunately, I have not yet gone over a sufficient number of histories of the birds of passage and well-to-do patients to make a separate series of them. Eliminating the soldiers alone would bring the percentage of immediate infections over 50. The more the family and their movements are known to me the greater the number under the heading I.

Discussion.

The authoritative view, and the one most generally accepted, is that direct infection in tuberculosis is negligible, and that measures taken to prevent this are waste of time or almost useless. (Many, it is true, would admit an exception in the case of children.) Someone has said, "Whatever is generally accepted is usually untrue"; and although this is an over-statement for the epigram's sake, it is certainly unsound to regard anything as true merely because it is generally accepted. Cases of tuberculosis may be divided ætiologically into (1) those due to a remote childhood infection, often untraceable, which has been rekindled in later life by overwork, illness, poverty, or other debilitating influence; and (2) cases due to an immediate infection, at any period of life, with sufficient virus to break down the patient's resistance at the time. This may be a larger or smaller dose according to the resistance of the individual, but very few humans can withstand a dose of tubercle bacilli if it is sufficiently massive.[1]

The recognition of these two classes is most important in regard to measures for the elimination of tuberculosis. Better housing, better wages, and so forth are helpful, but whatever is done overwork, poverty (often due to laziness or self-indulgence), and illness can never be abolished, and so the first class is largely beyond our reach. On the other hand, cases of clinical tuberculosis due to immediate infection can be prevented, and when we have gone so far it may well be found that incidentally the other class of case has ceased to occur.

---

[1] There are also intermediate cases between these two classes, in whom there is more or less broken health from the time of a childhood infection to a final, fatal breakdown in adult life.

The main channel of infection, and the only really important one, is from the sputum of a tuberculous patient. Bovine infection, urinary infection, and even the more important source from discharging sinuses, are all of secondary importance.

Fortunately, moreover, the majority of cases of pulmonary tuberculosis are not infectious, or only slightly so, if reasonable precautions are taken. It is the advanced case, that may take from 2–15 years or more to die, that is the danger (possibly also the so-called "innocent" cases). One such advanced case may in course of time give rise directly to 100 or more new cases, and indirectly to ten times this number. Yet in all discussions on the prevention of tuberculosis the speakers confine themselves to housing, poverty, sanatoriums, dispensaries, &c., and no serious attempt has been made to deal with tuberculosis as an infectious disease.

The attitude of the public, of our profession, and of the law towards infection in tuberculosis may justly be likened to "straining at a gnat and swallowing a camel."

On the one hand, I know of cases where the clergy have been unwilling to visit tuberculous patients on account of the risks. One wealthy man asked, through his solicitors, for the removal of a girl on his estate because she used to sit in a cottage garden within 50 yards of one of the roads to his mansion, though quite half a mile therefrom. The chairman of a hospital committee asks that a case of spinal caries be removed from hospital because tuberculosis is not allowed in the hospital for fear of infection. The house surgeon at another hospital refuses to admit a case of pleural effusion because "it is not fair to the other patients to admit these tuberculous cases!" The mistress of a maid who has a slight hæmoptysis will not allow her to remain in bed for a day or two in the house where she is in service, but insists on her immediate removal to the union infirmary for fear of infection. A medical officer of health insists on the isolation or removal of a boy at an orphan home because he has been notified as a case of tuberculous adenitis, when 30 per cent. of the other boys have a similar condition more or less marked. The risk of infection in all these cases was purely imaginary. This I call straining at a gnat.

On the other hand, I know of an infective case of tuberculosis engaged in distributing milk. His habits are none too clean. He goes out early in the morning, and has his morning cough over the milk. I know another case with about half an ounce of sputum daily, often highly infective, who is engaged as a butcher (although meat from a cow with a tuberculous udder is not allowed to be sold). In another case an untrained woman, who spends most of her time attending an advanced case of tuberculosis, spends the rest of her time in the dairy preparing cream and butter for the market. I am authoritatively informed that there is no legal remedy for any of these cases. The law recognises the danger of the relatively unimportant bovine tuberculosis, but does not trouble about an infective human. This is swallowing a camel.

I know again of one practitioner who advised a landlady to get rid of a lodger with glandular tuberculosis, quite uninfective; and of another who advised that a child with bronchitis should sleep with a grandmother who had advanced tuberculosis because it was warmer; yet another practitioner notified a man employed at a boys' school only after two years' treatment, and when the disease was far advanced, giving as his reason for the delay that if he had notified the case previously the man would have lost his job.

Illustrative Cases.

The following is an account of two cases which illustrate how tuberculosis is spread:—

1. An invalided soldier is found with his wife and two young children occupying two rooms. This patient is highly infective and brings up half a pint of sputum daily. He is sitting shivering over the fire before which the children are being washed. At his side in the fender is a dry spittoon with sloping sides; at the bottom of the spittoon is dry or drying sputum, on the sides are blobs of sputum, and starred all round the receptacle is more sputum where the patient has made "bad shots" at the spittoon. I was able to get this man a separate bedroom, and a few months later to persuade him to go into a tuberculosis hospital, where he died. When the family were seen again, four months after his death, the wife had been getting thinner and had physical signs of active disease at both apices, one child was ill with pulmonary and glandular tuberculosis, and the other a suspect. A child born since the husband's death was the only healthy member of the family. Others might interpret this as a case of hereditary predisposition and selective mating, but such an interpretation would seem far-fetched.

2. On another occasion I visited a young man of 25 in a seven-roomed house with nine inmates. The patient, who has advanced disease, lies in a room adjoining the kitchen and where the family frequently have their meals. The room is a sitting-room with a bed in it, and in the centre stands a large table. Alongside the patient's bed two or three newspapers are spread as a receptacle for his sputum, the mother informing me that he will not use anything else. Scattered over the paper are lumps of nummular sputum in varying stages of desiccation. On the carpet beyond the papers are a few more nummuli, and on the table leg there is a mass which has hit the leg high up and trickled downwards some 18 inches. Between the papers and the door, and on into the front room, are traces of sputum carried on the feet of visitors. The patient has since died of tuberculosis, and also one sister; one brother has been in a sanatorium recently, but is still ill; another sister is in a sanatorium now. I have not examined all the household yet, as the family consists mainly of adults, and therefore difficult to find in at the same time; but so far all that I have seen are tuberculous, including a New Zealander who married a sister of the patient and went to live there. Yet these people were somewhat apathetic and careless about the whole matter.

I have sometimes found a little colony of tuberculous persons in a more or less isolated spot, such as one street of a village, and I am inclined to attribute the existence of the colony to conditions of infection similar to those described, rather than to the influence of the local climate or the prevalence of some special wind.

Reply to Previous Criticisms.

I should like also, if so permitted, to take this opportunity of replying to the kindly and courteous criticisms in an editorial published in THE LANCET of Oct. 11th, 1919, dealing with my paper on "conjugal tuberculosis."

1. The difficulty in comparing the work of some older writings in this field is that pulmonary tuberculosis meant to them what we should call advanced disease; they would not classify as tuberculous a patient with a few symptoms and physical signs, who gradually got better and not worse. Even now the surgical conception of a

tuberculous joint (knee, elbow, &c.) is that of advanced tuberculosis of the joint, though, indeed, there are many stages before a typical "white swelling" is produced.

2. It is said that German insurance offices do not reject persons because of a history of exposure to infection, even to conjugal infection. Writing under correction, I do not think this is true of countries other than Germany. Other factors come into the calculation, of course, but short of rejection I think the lives are usually "weighted" in one way or another. Moreover, the class of patient of whom I write does not come into insurance statistics to any extent, for, except perhaps in a "death club," they do not usually insure.

3. It is quite true that my figures apply to rural areas, but such an area is surely the most suitable for studying the spread of tuberculosis. Just as the dermatologist looks at the edge of an eruption to discover its nature, so problems of this kind are best investigated in rural areas where people do not move about much, and where the history of individual lives is much better known.

The objection that many cases included may be virgin soil is quite sound. I would add, virgin soil or relatively virgin soil (though, as a simile, a relative virginity does not appeal to me), meaning that in addition to cases receiving in childhood a dose of bacilli which protects them there are others whose dose is insufficient to give more than a slight protection. The number of the insufficiently protected, in town as well as country, must be very great, and accounts, perhaps, for a large number of our tuberculosis deaths. The number of children, moreover, who lose their lives in the process of immunisation is also great. It would surely be better to make our aim the *detuberculisation* of the community rather than fatalistically to regard tuberculisation as permanently inevitable and meet it only by indirect means. A similar view was held as to small-pox before Jenner's time.

4. The criticism concerning the influence of poverty is also sound. I do not think my statistics would apply to the well-to-do. Everyone must admit that if the resistance is lowered by subnutrition, worry, and overwork the liability to tuberculosis must be increased. But poverty also increases the possibilities of infection; it means more intimate contact with the patient, smaller rooms, and windows closed for the sake of warmth. Again, poverty is too often accompanied by ignorance of the risks of infection and of the most ordinary precautions. In a poor household one frequently sees a casual indifference to infection, or openly preached fatalism (generally by grandmothers), while among the better classes there exists almost a terror of infection, and the tuberculous patient is made a leper indeed.

5. With the last paragraph of the editorial I entirely agree. It is by no means necessary to separate all the tuberculous from the non-tuberculous. Massive infection is what really matters, and commonsense measures of prevention are all that is needed. But no such measures have yet been attempted.

To Dr. C. Muthu (THE LANCET, Oct. 18th) I would say that I did not intend my paper on conjugal tuberculosis to be a record of the "mere presence of tuberculosis among married people or among those living under the same roof," but a study of the incidence of tuberculosis among the mates of tuberculous persons *compared with* the incidence among contacts of tuberculous persons other than husband and wife, and *controlled by* an examination of the contacts of patients to be considered non-tuberculous. Moreover, I make no claim to be always right. If my conclusions are correct it is important that they should be recognised and acted upon; if I am wrong the truth will only shine more brightly for contact with my errors. To Dr. R. C. Holt (THE LANCET, Nov. 8th) I would say that he is probably quite right, but that I am anxious not to spoil a good case by any apparent exaggeration. (I was in general practice myself for several years.) Apart from public criticisms I have been surprised at the number who have written expressing agreement.

Suggestions.

I have no wish to decry in any way the attempts to improve housing conditions, to preach hygiene, and eliminate poverty, but we seem to get no further with tuberculosis, and I feel convinced that the only way to tackle the problem is to consider it as primarily and mainly a problem of infection, and to deal with it on these lines. So far, as I have tried to indicate, this has not been done. The Royal Society of Medicine discusses the problem, but infection is regarded as a secondary matter and comparatively unimportant, and I read in vain through the speeches at the recent antituberculosis congress for any sign that the speakers regard the problem as one of infection. Much has been, and still is, hoped for from the new Ministry of Health and its advisory council, but so far we seem merely to revolve more vigorously round the same circle: housing, hygiene, more sanatoriums, more dispensaries, elimination of poverty, better feeding, and so forth. Yet I believe that the present Government is more ready than any we have had in the past to act energetically for the benefit of the community, and on the right lines too, if only it is advised definitely and forcefully enough.

Apart from the application to tuberculosis of regulations similar to those in force for other infectious diseases there is an unlimited field for research in other methods of preventing the infection.

For instance, it occurred to me some time ago that chlorine being highly inimical to the tubercle bacillus the frequent inhalation of a spray containing dichloramine T. of suitable strength might render an infective patient less infectious or even non-infectious. Unfortunately pressure of work, and war time, have prevented me from going very far on these lines, but I am encouraged to continue, and similar experiments with other drugs might be tried. The inhalation of very diluted oxides of nitrogen seems to assist the prevention of influenza; may we not find some similar method of value in tuberculosis?

Then let us have written in plain English and scattered broadcast a short circular explaining that tuberculosis is an infectious disease, but that fortunately only a minority of those affected, and mainly advanced cases, are infectious to others, and setting forth also the best way to avoid infection. People want a clear lead in this matter. It is very little use to go on repeating to the public that there is no practical danger of infection when every educated adult member of society can recollect, in his own personal experience, what seem to him clear cases of infection. Such statements give him a mistrust for his advisers, and this reacts in more ways than one.

ON INDIARUBBER WOUND DRAINS.

BY ARTHUR EDMUNDS, C.B., M.S., F.R.C.S.,
SURGEON, KING'S COLLEGE HOSPITAL; SURGEON,
GREAT NORTHERN CENTRAL HOSPITAL.

FOR some time past I have employed the following devices for drainage, which, though probably not original, have proved extremely useful.

1. It is often desirable to drain the rectum by means of a rubber tube inserted into the bowel to allow the passage of flatus and to prevent concealed hæmorrhage. For this purpose two large holes can be cut in the side of the tube opposite one another; the tube is then split down into these holes with a pair of scissors, giving an apparatus which Fig. 1 amply explains. The method of using this is shown in Fig. 2. The large holes weaken the tube at a definite point, and enable it to be opened out on a sort of hinge, so that the split portions lie comfortably in the middle line along the natal cleft, where they are kept in position by a pad.

FIG. 1.

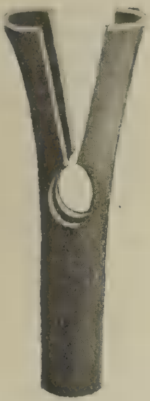

FIG. 2.

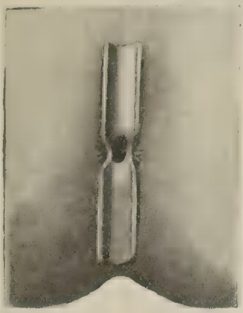

2. For the drainage of acute empyemata. This method of cutting a drainage-tube is shown in Figs. 3 and 4 and is a modification of the preceding device. I originally used the rectal tube which I have just described, but the movements of the chest wall tend to suck the tube in or to push it out, so that free drainage is obstructed. Fig. 3 explains how the tube is prepared. Instead of cutting a hole, a slit is made into the tube which marks out a flap like a Gothic arch. This is done on each side of the tube at opposite points, and the portion of the tube which is destined to remain outside the chest wall is split up, the incisions meeting the Gothic arches at their apices. The preparation of this apparatus only requires four snips with the scissors and can be carried out in a few seconds. When the split portions of the tube are opened out an apparatus is obtained as shown in Fig. 4. After the chest wall has been opened and pus evacuated, a suture should be passed deeply through the superficial tissues on each side of the centre of the incision, leaving room between them for the passage of the tube. These sutures, which should be of stout silkworm-gut, are then tied so as to leave two long equal ends. In Fig. 4 the wound is diagrammatically represented by the dotted line *a*.........*a'* and the stitches, where they pass through the skin and subcutaneous tissue, by the loops *b*.........*b*. The drainage-tube is then put into position and the flaps bent outwards so as to lie in the long axis of the wound where they are secured by tying around them the long end of the two sutures. In order to make this more secure two little cuts should be made on each side to take the stitch as shown at *c* in Fig. 4. The sutures holding the tube in place should be tied in a bow and left long.

The advantages of this apparatus are that (1) it is very firmly fixed to the chest wall and so does not slip in and out, and (2) the small flaps of rubber which have been described as resembling Gothic arches (Fig. 4 *d*) hold the sides of the wound apart and prevent the skin falling over the mouth of the tube. This tube will remain in place as long as the stitches hold—that is to say, usually for a week or ten days, by which time the acute stage of the disease will be passed, and it will be possible to retain a drainage-tube with an ordinary safety-pin, if it has not been possible to remove it altogether.

FIG. 3.

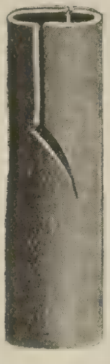

FIG. 4.

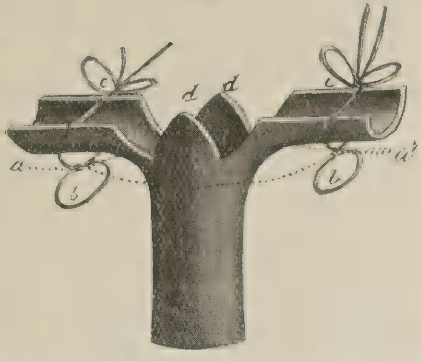
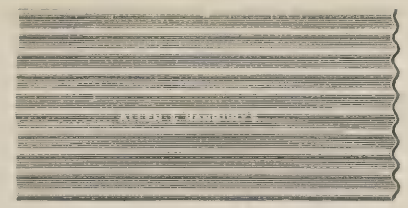


To remove the tube in the early stages of the case all that is necessary is to untie the bow securing each half of the split tube, when the tube is quite free and can be drawn out of the chest. The sutures can then be re-tied and the tube is once more firmly fixed.

3. Drainage by means of corrugated rubber sheeting. Although for some cases the drainage-tube is indispensable, there are others in which it has its drawbacks, and I now use extensively the corrugated rubber sheeting, which has been prepared for me by Messrs. Allen and Hanburys. This substance (shown in Fig. 5) is made of fairly stout sheet rubber, and for many cases serves all the purposes of a drainage-tube, while possessing certain advantages.

FIG. 5.



At first I used this material rather tentatively, but I am now using it very largely, especially for temporary drainage after extensive operations, where there is likely to be a good deal of oozing, such as amputation of a limb, excision of the breast or glands in the neck, or removal of large renal tumours.

When a cavity has to be drained through a muscular layer—e.g., in draining an intra-abdominal abscess through a stab wound—I prefer a fairly stout tube, but where there is not much sepsis or where the drainage is a precaution mainly concerning the abdominal wall, a strip of corrugated rubber is more satisfactory.

For draining suppurating tracks, spaces under suppurating flaps—e.g., after an operation for cellulitis—I prefer it to drainage-tubes. It is infinitely more comfortable for the patient than a tube, and can be removed practically painlessly. Owing to its flexibility it is less likely to cause trouble from pressure, but it is sufficiently stiff to allow of its re-insertion when prolonged drainage is necessary.

The material is made in sheets 12 inches long by 6 inches wide, from which strips can be cut of appropriate length and width. A length of an inch or so can be left hanging out of the wound, and when this tends to depress one side of the wound unduly the projecting portion can be split down to the skin level and the two halves turned back in opposite directions.

ON THE USE OF THE ACTUAL CAUTERY IN GASTRIC ULCER

By JAMES KIRKLAND, M.B., C.M. Glasg.,
LATE SURGEON TO HOLBORN MILITARY HOSPITAL.

For five or six years I have used the actual cautery in place of the knife in treating some cases of gastric ulcer. My reason for so doing is threefold. (1) On several occasions on reopening abdomens for recurrent symptoms, after excision of gastric ulcer had been performed some time previously, I have found excessive contraction and cramping of the lesser curvature, which evidently caused acute angulation of the duodenum with the pyloric portion of the stomach, resulting apparently, in some cases, in duodenal ulceration. (2) In excision of the usual wedge-shaped portion of the stomach wall bearing the ulcer there is of necessity a great loss of tissue, which means loss of mobility and function, always a serious matter. (3) Excision alone, without gastro-enterostomy, frequently fails to relieve symptoms; this, in my opinion, may be largely due to the above-mentioned loss of tissue, mobility, and function.

With these considerations in my mind I decided to try some other method of treating gastric ulcer, which would as far as possible eliminate these unsatisfactory sequelæ. I am not an advocate for the excision of every excisable ulcer. With the use of the actual cautery excision is unnecessary, and there is a minimal loss of tissue, mobility, and function. Healing is rapid and satisfactory. We know that heat is one of our very best germicides, and we also know that with an adequate application its effects extend beyond the point of application to a distance of at least 2 cm.

Clinical Basis of Treatment by Cautery.

In cases where patients have survived untreated perforated gastric ulcer a cure of the ulcer and its symptoms follows. It is upon these two factors—viz., heat and perforation—that the efficiency of cautery treatment depends. To treat an ulcer satisfactorily with the cautery the stomach, and particularly the ulcer-bearing portion, should be sufficiently free and movable to allow of safe and adequate exposure. The majority of ulcers which rupture are on the anterior surface towards the lesser curvature, and it is just in this position that the cautery can most advantageously be used. It is also the most frequent site of ulcers which are excised.

There may be some doubt regarding the applicability of this treatment to cases showing signs of malignancy. It is probable, however, that it is even more efficient than the knife. It is an established fact that in both primary and secondary cancer of the stomach the line of demarcation between diseased and healthy tissue is sharply defined. If the diseased portion be excised with the knife with a fair margin, say half an inch, of healthy tissue, it is probable that the whole of the disease has been removed. We know that heat has a very powerful and destructive effect upon cancer cells, and that this destructive effect is exerted for some distance, at least an inch, in every direction from the point of application, assuming such application to be adequate. It follows that the disease may thus be eradicated with more certainty and less loss of tissue and function than is possible with the scalpel, always assuming that in both instances there are no metastases.

There is one important point also noted by American writers, who have just lately been using the cautery extensively, that hæmorrhage has not followed in one case so treated, whereas it is one of our greatest fears in knife excision.

Result in Cases Treated by Cautery.

So far my cautery cases are comparatively few. I have, owing to the war and its vicissitudes, lost the run of several. Two are of too recent a date to make any definite statement regarding them. The following eight I have seen within the last few weeks.

Perforated Ulcers (3).

(1) Male, age 31. Ulcer on anterior superior surface, perforated about 4½ hours; cured.

(2) Male, 35. Ulcer on anterior surface near pylorus, perforated about 3 hours; cured.

(3) Male, 49. Ulcer on anterior surface, perforated about 5 hours; cured; convalescence protracted owing to pleuritic infection. No subdiaphragmatic abscess.

Immediate gastro-enterostomy was done in all three cases.

Unperforated Ulcers (5).

1. Female, 43. Symptoms present about eight years; position of ulcer anterior superior surface, ? malignant; apparently cured.
2. Female, 29. Symptoms about four years; position of ulcer anterior; cured.
3. Male, 35. Symptoms present for an indefinite but considerable period; position of ulcer lesser curvature; cured.
4. Male, 52 (?). Symptoms present for an indefinite time; position of ulcer on lesser curvature, ? malignant; apparently cured.
5. Female, 33. Had "stomach trouble" all her life; two ulcers on and near lesser curvature; cured.

In all cases the ulcer was completely perforated with cautery point and gastro-enterostomy, either immediate or secondary, was done.

When treating an ulcer on the lesser curvature it is well carefully to isolate the crater by reflection of a small flap of gastro-hepatic omentum over the ulcer area. A small but definite point will be seen, which can scarcely be mistaken. This is the apex of the ulcer crater, and the spot through which the cautery point can be thrust. After thorough cauterisation the ulcer is closed by approximation and overstitching, and the reflected flap is replaced and sutured. Whether or not an immediate gastro-enterostomy should be done is for the surgeon to decide. No hard-and-fast rule can be laid down.

Conclusion.

This article has been written with a view to a discussion, so that the treatment by cautery may be established if considered worthy. I claim that by this method it is possible to deal with a larger percentage of ulcers than with the knife, with less risk to life, less loss of tissue, mobility, and function, and with greater certainty of sterilisation of the parts treated.

Wimpole-street, W.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF

GUNSHOT WOUND OF THE LARYNX

WITH IMPACTED FOREIGN BODY. OPERATION; RECOVERY.

BY J. WALKER WOOD, L.R.C.P. & S. EDIN., L.R.F.P.S. GLASG.,

LATE CIVIL SURGEON, HAMPSTEAD MILITARY HOSPITAL, AND CAPTAIN, R.A.M.C.

GUNSHOT wounds of the larynx with impacted foreign bodies not immediately fatal are of sufficient interest to justify the recording of the following case recently under my care.

Private L. J. W., 3rd Grenadier Guards, age 35. Wounded on 3/9/18. On admission to Hampstead Military Hospital on 8/9/18 his condition was as follows: small healed wound on right side of neck with some surgical emphysema around the wound, complete loss of voice, and a marked inspiratory and expiratory stridor.

Laryngoscopic examination (see Fig. 1).—Swelling of the left ventricular band, obscuring a view of the left vocal cord: swelling and œdema of left arytenoid and ary-epiglottic fold, partially closing glottic aperture. The right vocal cord was represented by a grey sloughy band, injured by the projectile on its passage across the larynx from right to left. The left side of the larynx was immobile and the movement of the right cord was limited. I decided that the foreign body was somewhere in the region of the left arytenoid. An X ray examination revealed the presence of a metallic foreign body in the region of the left crico-arytenoid articulation.

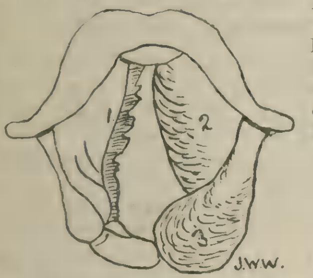


FIG. 1.—1. Laceration, right vocal cord. 2. Swelling and œdema, left ventricular band. 3. Swelling and œdema, left arytenoid and ary-epiglottic fold.

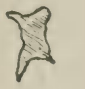

FIG. 2.—Foreign body. Actual size. 8 mm. × 9 mm.

For the following reasons I decided to attempt removal of the fragment: (1) the chance of septic perichondritis and œdema of the glottis occurring; (2) the possibility of dislodgment of the fragment with the grave danger of glottic spasm; (3) interference with the function and mobility of the left vocal cord.

The only operation which would give the necessary access being thyrotomy or laryngo fissure, after a consultation with Captain A. G. Wilkins, R.A.M.C., our anæsthetist, we decided upon rectal ether as the best anæsthetic. The operation was performed on 16 9 18.

Operation.—Thyrotomy incision. Median tracheotomy through isthmus of thyroid. There was considerable emphysema of tissues of neck, which increased the hæmorrhage at this stage of the operation and delayed its initial stages. Thyroid cartilage split from above and, after sponging interior with cocaine, sponges were packed down on convexity of tracheotomy tube and up into pharynx. The foreign body was located in the left crico-arytenoid articulation and removed. (See Fig. 2. actual size.) The muco-perichondrium of the wings of the thyroid cartilage having been drawn together with fine silk the tracheotomy tube was removed, the whole wound being closed except two sutures threaded, but untied at the lower angle of the wound. These were tied 48 hours later. The further progress of the case was uneventful. Following the operation patient developed slight bronchitis for a few days, but the voice was much stronger than before operation. For 48 hours there was slight air leakage through the lower part of the wound, but this rapidly closed; there was no dysphagia.

Present condition, 11/10/18.—The movements of the right vocal cord are normal. There is still some impairment of movement of the left vocal cord. Swelling of the left arytenoid has almost disappeared. The voice is still weak, but very much stronger than immediately after the operation and before it, and is strengthening daily.

Anæsthetic Note (by Captain A. G. WILKINS).

Intra-rectal ether advised in order to avoid (1) interference with surgeon, (2) post-operative bronchitis and sickness, (3) risk of cardiac muscle failure owing to sepsis and a dilated heart (patient had other very septic wounds): these conditions made chloroform inadvisable.

Pot. brom., gr. xx., given at 8 P.M., Sept. 15th. At 9 A.M., Sept. 16th, hypodermic injection: morphine, 1/6 gr., hyoscine, 1/150 gr., atropine, 1/100 gr.; at 9.15 A.M., enema of paraldehyde, ʒi., ether, ℥iv., and olive oil, ℥ii., given as slowly as possible (eight minutes); catheter passed three inches within bowel. Enema retained. At 9.30 A.M. satisfactory anæsthesia, only faint corneal reflex. Colour and respiration satisfactory and patient removed to theatre. At 10.15 A.M., operation commenced, anæsthetic deepened by covering mouth and nose with towel. At 10.30 A.M. when larynx opened pledget of wool soaked in 10 per cent. cocaine and adrenalin swabbed round interior of larynx. Diminution in stridor followed. Pulse good. Breathing quicker. 11 A.M., operation completed. The bowel was then washed out to get rid of remaining ether. At 1.30 P.M. patient opened his eyes but was still dazed. 2 P.M., completely conscious and could understand, and reply to, remarks made to him. There was no sickness.

Remarks.

This is the first occasion that I have done a thyrotomy with rectal ether, and I cannot speak too highly of it as *the* anæsthetic for this operation. Its advantages are: 1. The anæsthetist is out of the way and the surgeon is not hampered with anæsthetic gear about the field of operation. 2. During the operation there is less coughing, which is apt to be troublesome when chloroform vapour is pumped in through the tracheotomy tube. 3. There is no struggling while the patient is coming round; a prolonged period of rest is followed by a good natural sleep without sickness. 4. There is less risk of post-operative pneumonia and bronchitis than when the anæsthetic is administered through the tracheotomy tube.

I desire to record my thanks to Captain Wilkins for the excellent anæsthetic and for his notes thereon; and to Dr. A. R. Roche, of Hampstead, for his assistance with the operation.

A CURIOUS CASE OF

EXTRUSION OF AN INHALED FOREIGN BODY.

BY GEORGE W. JOHNSON, M.A., M.B., B.CH. OXF.

ALTHOUGH it is well recognised that a foreign body after entering the air-passages may occasionally make its exit from an abscess in the chest wall, the occurrence is sufficiently unusual to render the following case of interest, in which the foreign body was a head of grass.

A girl, 2 years of age, was brought to me on July 24th with a fluctuating swelling, of about the size of a tangerine orange, in the right mid-axillary line, the centre of the swelling being over the seventh rib. The swelling was obviously an abscess, and was thought probably to be due to tuberculous disease of a rib. The mother could give no history beyond the fact that the swelling had been noticed for a week, and that the child up to that time had been in her usual health. The child was very difficult to examine, but no sign of any gross lesion in the lungs was detected. Operation was refused. A few days later the abscess burst, discharging a large quantity of pus. The child seemed ill and the temperature remained raised. About August 16th a head of "barley grass" 1¾ inch in length was discharged from the abscess. The mother then stated that about a week before the abscess was first noticed the child had had a choking fit, and that she had taken some similar grass away from her, but had not in any way connected the two events.

After the discharge of the grass the abscess rapidly healed, and at the time of writing (Dec. 17th) the child is in good health.

Gainsborough.

NOTE ON A CASE OF

ENTERIC CYST CAUSING INTUSSUSCEPTION.

By C. W. G. Bryan, *M.C.*, F.R.C.S. Eng.,

SURGICAL REGISTRAR, ST. MARY'S HOSPITAL; SURGEON TO OUT-PATIENTS, PADDINGTON GREEN CHILDREN'S HOSPITAL, AND HAMPSTEAD GENERAL HOSPITAL.

This case is placed on record on account of the rarity of the condition.

L. C., a boy of 6 years, was admitted to the Paddington Green Children's Hospital on May 29th last with a history of abdominal pain of one day's duration, accompanied by frequent vomiting. The bowels had not been opened since the pain commenced. Patient was subject to occasional attacks of constipation with headache and vomiting; otherwise he was always healthy.

Condition on admission.—A well-nourished boy of average development. Generalised abdominal tenderness, no rigidity. Circumscribed swelling palpable in the right hypochondrium. Nothing abnormal on rectal examination. Pulse 124, temperature 99°F., respirations 24. A simple enema was given without result. On the two following days the boy vomited occasionally, and complained of abdominal pain, but his general condition improved. On June 2nd, three days after admission, the bowels opened and frequent offensive stools were passed for two days; no pain or vomiting. On the 4th vomiting and pain recommenced, and lasted until the 7th. Bowels opened on the 5th.

The case came under my care on June 7th. The patient was now having paroxysmal attacks of extreme abdominal pain. Abdomen slightly distended. Visible peristalsis of small intestine. Indefinite tumour of right lumbar region, masked by rigidity. Face pale, anxious, and pinched. Pulse 120, temperature 100·2°, respirations 24. The history and signs then were clearly those of acute intestinal obstruction.

Operation.—Under general anæsthesia the abdomen was opened through the inner part of the right rectus. Small amount of clear fluid in the peritoneum. The ileo-cæcal region was delivered and an intussusception of the last part of the ileum, which had progressed less than one inch, was reduced easily. It was then found that there was a thin-walled cyst, the size of a tangerine orange, in the anti-mesenteric wall of the ileum. The cyst filled the lumen of the gut, two-thirds of it being in the ileum and one-third in the cæcum, the edges of the ileo-cæcal orifice constricting the cyst.

An effort was made to dissect out the cyst, but this could not be done easily, and the attempt was soon given up in view of the collapsed state of the boy and the dragging necessitated by the fixity of the cæcum. After packing off, the cyst was incised and a large amount of opaque fluid and jelly-like mucus was evacuated. The cyst was marsupialised by suture to the lower part of the abdominal wall incision. This caused some kinking of the gut, and the cyst wall appeared to form a considerable mass inside the lumen of the ileum, so a lateral anastomosis was made rapidly between the cæcum and the ileum proximal to the cyst. The abdominal wall was closed in layers with a strip of rubber tissue leading into the cyst.

I decided, working as I was through an incision near the middle line, that it was impossible without severe shock to dissect out the cyst, and for the same reason a primary ileocæcal resection was out of the question. Subacute suppuration of the interior of the cyst occurred, but otherwise recovery was uneventful, and the rest of the wound healed soundly.

Second operation on July 8th.—Spinal anæsthesia by a 5 per cent. aqueous solution of novocain. The old wound scar, with a sinus leading into the shrunken cyst, was excised from the abdominal wall and the general peritoneal cavity packed off. The cæcum and the terminal 6 inches of the ileum were excised, including the cyst and the lateral anastomosis which were involved in adhesions. End-to-end anastomosis of ileum to ascending colon was made, the end of the latter being closed each side to make its lumen correspond with the ileum. Abdominal wall closed in layers; right loin drainage for 48 hours. There was no marked shock and no vomiting. The bowels were opened on July 10th. A stitch abscess of the abdominal wall occurred, and the remains of a catgut stitch were removed on July 29th; recovery was then uneventful, the wound healed soundly, and the patient was discharged to the convalescent home on August 6th.

I saw him in October. He had a sound linear scar, had no symptoms of any sort, and appeared quite healthy.

Remarks.

Examination of the specimen shows the cyst situated in the anti-mesenteric wall of the ileum, close to the ileocæcal valve. In its shrunken condition it is 1 1/10 in. in diameter and projects into the lumen of the gut. Microscopic examination shows a thin layer of circular muscle in the inner wall of the cyst, so that it is intermuscular, as in the case described by Gfeller and mentioned in Keen's "Surgery."[1] Such cysts are considered to arise in persistent relics of the omphalo-mesenteric duct, and may occur between the fibres of the circular muscle of the intestine, as in my case, or may be subserous. Diagnosis has not been made before operation, but should be possible, if this rare condition is borne in mind, in the presence of a tumour with recurring attacks of intestinal obstruction. As a rule such a cyst could be dissected out of the gut wall and the muscle closed by suture. In the case that I record this was inadvisable owing to the inaccessibility of the ileocæcal region and the collapsed condition of the patient. An oblique iliac incision would have given better approach to the region.

I wish to express my thanks to Dr. E. H. Kettle for kindly examining the specimen, and to Miss N. E. Trouton, house surgeon to the hospital, for careful notes.

Medical Defence Union.—At the meeting of the Executive Committee of the Medical Defence Union held on Dec. 22nd, 1919, the general secretary reported that three members had forwarded donations to the funds of the union as a mark of their appreciation of the services rendered to them by the union in cases in which they had recently had occasion to apply for assistance. One of the members stated that the amount of his donation (which was substantial) was really no measure of his gratitude.

Medical Societies.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this society was held on Dec. 5th, 1919, Dr. DOUGLAS RUSSELL, the Vice-President, being in the chair.

Dr. J. W. MCNEE read a short paper and gave a microscopical demonstration on

The Pathology of Irritant Gas Poisoning.

After pointing out that during the war a much larger number of gases had been employed by the Germans than was generally believed, Dr. McNee described three main forms of gas poisoning. (1) *Chlorine.* This was the original drift gas used by the Germans and was dangerous only where troops were quite unprotected, as in the first attack. It acted as a direct irritant of the pulmonary system, causing intense œdema of the mucosa, and, by the coughing and spluttering set up, a disruptive emphysema, with, in addition, a devitalising effect on the lung tissue. Many of those attacked died in two days, practically drowned by the œdema. Those who recovered suffered from acute bronchitis. (2) *Phosgene.* This was used first as a drift gas and later in shells. It was not irrespirable, and, indeed, might be inhaled in some quantity before its presence was recognised. It was extremely poisonous, causing death in one minute when inhaled in concentrated form. It did not greatly damage the bronchial mucous membrane, but produced an intense œdema of the lung. Two types of cases were observed: (*a*) Men who reacted and displayed a purple lividity; these recovered if well bled so as to relieve engorgement of the right heart. (*b*) Men who were pale and cyanosed; these died practically at once. Among remoter effects were emphysema and a hyaline thrombosis of the capillaries in many parts of the body—e.g., in the walls of the lung alveoli, in the renal glomeruli, and in the brain, where they caused so-called ring hæmorrhages. (3) *Dichlorethylsulphide, or mustard gas.* This was the best gas from the German point of view, as, though not so fatal, it caused more casualties than all the others put together. The actual substance was a greenish-brown fluid, with a boiling point of 217° C., so that when deposited anywhere it was not easily volatilised but remained poisonous for 5, 6, or 7 days. Its primary effects were on the bronchial tree—viz., intense inflammation with necrosis of the mucous membrane and the pouring out of a false membrane like that of diphtheria. This formed a pabulum for micro-organisms which, growing there, set up broncho-pneumonia and abscess of the lung. Among other effects were acute dermatitis and severe conjunctivitis characterised by swelling and œdema, temporary blindness, and in some cases opacities of the cornea which might last for months. A knowledge of these effects of poison gas was of importance to medical men, both in practice and in pensions work, as many of the results were permanent, such as bronchitis (often becoming chronic), asthmatic conditions, fibrosis of the lung (particularly after chlorine or phosgene), and thrombosis or ring hæmorrhages in the brain.

Dr. JAMES CARSLAW and Dr. JOHN M. COWAN made a communication on

The Fatality of Peptic Ulcer and the Importance of Early Diagnosis.

In a series of 112 cases treated in Glasgow Royal Infirmary during the years 1906–16, 14 patients died as the result of the ulceration—a mortality of 12·5 per cent. A similar mortality had been reported by several authors, though figures ranged from 2 per cent. (Leube) to 18 per cent. (Bulstrode). Such figures might not, however, represent the true mortality, as some patients died from causes other than ulcer, and some of the 14 cases referred to might have died after leaving hospital, either from ulcer or from causes indirectly associated with it. Post-mortem evidence showed that ulcer was much more common than was appreciated clinically, and that while clinically the majority of cases occurred in women, post mortem the majority occurred in men. In a contrasted series of 30 cases (soldiers) treated in the 3rd Scottish General Hospital from 1914 to 1919, one patient died during his residence, having been admitted with recurrence of hæmorrhage and too ill for operation. Of four patients submitted to operation three appeared likely to benefit permanently by it, and one unlikely, as widespread adhesions prevented the performance of gastro-enterostomy. Nine patients improved under treatment but relapsed on ordinary diet and had to be invalided out of the service. No fewer than 15 of the patients without any serious gastric symptoms showed occult blood in the stools, some for even long periods. Most of these were relieved from their symptoms after a few days in hospital, and all were dismissed "well." These were nearly all young men and suffered from a type of ulceration not likely to be seen in civil hospitals or to receive serious consideration from private doctors. Such cases probably supplied a number of those tragic incidents of sudden severe hæmorrhage or perforation without warning which everyone at times met with, and warranted a plea for special care in the examination of patients suffering from "dyspepsia," and in particular for the examination of the stools for occult blood.

Mr. HENRY RUTHERFURD exhibited illustrations of Diseases and Injuries of the Neck of the Femur.

RÖNTGEN SOCIETY.—An exhibition of radiographic prints by members of the Röntgen Society will be held at the Royal Photographic Society's House, 35, Russell-square, London, W.C., from Jan. 6th to Feb. 7th. The exhibition will be open daily (admission free) from 11 A.M. to 5 P.M. and on the evenings of Jan. 6th and 13th till 9 P.M. On Jan. 6th at 7 P.M. at the Royal Photographic Society's House a lecture on the X Rays Approached from the Popular Standpoint will be given by Dr. George H. Rodman, F.R.P.S.

SOCIÉTÉ DE THÉRAPEUTIQUE, PARIS.—At a recent meeting of this society Dr. Edmond Lesné and Dr. Léon Binet read a paper on the Resistance to Poisons according to Age, in which they showed by the following experiments that the young animal can resist certain poisons better than an adult one: 1. A new-born cat could resist an injection of 0·62 mg. of cocaine hydrochloride per kilo of body-weight, whereas half of this dose killed an adult cat. 2. A mouse aged 9 days, and weighing 5 g., could resist an injection of 0·5 mg. of cocaine hydrochloride, a dose which proved fatal to a mouse aged 14 days and weighing 10 g. 3. Kittens aged 25 and 32 days could resist injection of 0·06 g. and 0·07 g. of morphia per kilo of body-weight, whereas an adult cat was killed by an injection of 0·05 g. per kilo. The greater resistance of young animals to poison is attributed to the activity of their glands with an antitoxic function, the greater vitality of their tissues, and the integrity of their excretory organs.—In a paper on the Prophylactic Value of Gaseous Disinfectants and Fumigation in Infectious Diseases Dr. Orticoni pointed out that the value of gaseous disinfectants and fumigation was due not only to their bactericidal action, but also to their forming a sort of mask which protected the upper respiratory tract from the penetration of micro-organisms. In certain factories in the South of France, where the workmen were exposed to the fumes of eucalyptus or the products of eucalyptus, the number of attacks of influenza was very small, and no fatal case was observed.—In a paper on the Importance of the Correct Interpretation of Urinalysis in Diabetes, Dr. Guelpa showed that diabetes presented two distinct stages which were of great importance from the point of view of prognosis and treatment. The first was a defensive stage characterised by an excess of urea and uric acid in the urine, and the second, which indicated a breakdown of the system, was characterised by a progressive diminution in the constituents of the urine, especially of the urea and uric acid.—In a paper on the Increase in Female Sterility Since the War owing to the Spread of Graves's Disease Dr. Raoul Blondel stated that the recent increase in the frequency of Graves's disease[1] was one of the principal factors of sterility among French women, one of the effects of hyperthyroidism being atrophy of the uterine muscle. Local examination in such cases showed a small pyriform uterus. Owing to the antagonism between the thyroid and the thymus Dr. Blondel recommended the administration of raw thymus in the form of lamb's sweetbread in addition to local measures such as massage of the uterus and dilatation by tents.

Reviews and Notices of Books.

GUNSHOT INJURIES TO THE BLOOD-VESSELS.

Founded on Experience gained in France during the Great War, 1914–1918. By Sir GEORGE MAKINS, G.C.M.G., C.B., President of the Royal College of Surgeons, Senior Consulting Surgeon, B.E.F. With 4 coloured plates and 60 illustrations. Bristol: John Wright and Sons, Ltd. 1919. Pp. 250. 21*s.* net.

THIS volume is a compilation in book form of several papers already written upon the subject, together with a special section furnishing the material from which the views expressed have been deduced. No attempt has been made to deal with the literature. Perhaps this was unnecessary, since the book itself will certainly rank as authoritative.

Wounds of large vascular trunks and the resulting associated lesions must have always special interest for those who deal with war wounds, and it is our knowledge as to immediate results and treatment of these injuries has increased considerably during the last five years. Prior to the war certain special features of gunshot wounds involving blood-vessels were well recognised, such as the tendency to spontaneous cessation of primary hæmorrhage, even with most extensive damage to the vessel; secondary hæmorrhage as a common sequel; and the frequent development of traumatic aneurysm. These characteristics and results have also been found during the present campaign, and though Sir George Makins has found reason slightly to alter the classification of the types of arterio-venous aneurysm, making six in all, they remain substantially the same. Treatment of such injuries, prior to the war, involved usually the ligature of the main artery affected above and below the lesion, with removal of the associated vein only when it prevented efficient treatment of the arterial injury. This line of treatment has been improved upon, and our information increased by a more accurate knowledge of the signs of injuries to arteries. This is particularly so as regards the examination of the heart and of the arteries locally. It has been found that the local systolic arterial bruit is frequently transmitted to the heart, and hence cardiac systolic murmurs of a pronounced character frequently accompany wounds of certain of the blood-vessels. An attempt is made to explain these murmurs which—and it is a point of special importance—may return with the resumption of active life. As regards the local murmurs, the author distinguishes various types, such as the soft "bellows" murmur, a loud "rushing" sound, or a musical whistle. In the presence of the arterio-venous communication either the systolic bruit or the venous roar may be the more prominent element. No characteristic difference in the murmurs has been observed between contused wounds produced by bullets and clean-cut openings produced by sharp shell fragments or bombs. With regard to the effect of these wounds on the general circulation, the ultimate course of arterio-venous injuries tends to support the view that extra strain is thrown upon the heart, so that resultant changes take place in the peripheral circulation.

As regards the actual mode of development of some of the consequences of arterial injuries, the author has demonstrated these by the use of some excellent coloured microphotographs showing sections of arteries in the various degrees of injury, ranging from contusion of the vessel to complete division. The evidence on this point seems to prove that injuries of the nature of contusions and non-perforating lacerations are not infrequently the cause of aneurysms or hæmatomata, which appear at a later stage. Little need be said of the primary treatment of these injuries, which has been substantially the same as in previous wars, and is still complicated by the presence of sepsis. The author insists on the great value of immediate direct transfusion of blood in severe cases of primary hæmorrhage. Secondary hæmorrhage is still a not uncommon sequel of lesions to blood-vessels, and Sir George Makins gives a very concise account of the most recent ruling on the treatment of this complication. War experience has proved that ligature at the bleeding-point is the correct treatment, and proximal ligature of the main trunk supplying the wound area is condemned. There is one exception to this rule: When bleeding is taking place from one of the vessels of the buttock close to the point at which this vessel emerges from the pelvis, ligature of the internal iliac artery or of its posterior division is considered the proper course. Plugging is recommended should ligature or forcipressure prove unsuccessful or impracticable. It may be said that all forms of treatment which have been tried are discussed in this volume, from ligature and removal to plastic operations upon the arteries and veins. When ligature with removal of the artery is adopted it is recommended that the vein be also occluded or, if necessary, partially removed during the operation. A special point is made as regards this coincident ligature of the main vein, the author stating that gangrene is more liable to follow should ligature of the vein be omitted. It is stated that should the artery only be ligatured the limb "bleeds to death" through the patent vein. With regard to Tuffier's tubes, the author states that in severe cases of injury to the popliteal artery gangrene is prevented by their use, and lays it down as a rule that the tubes should be removed at the end of four days. The volume closes with a detailed description of the various methods adopted in cases of injury to individual arteries.

The book is well finished and copiously illustrated by diagrams, X rays, and pictures, and is a worthy synopsis of war-won knowledge, which will be of practical service also in general and industrial practice.

POST-MORTEM MANUAL.

A Handbook of Morbid Anatomy and Post-mortem Technique. By CHARLES R. BOX, M.D., B.S., B.Sc., F.R.C.P., F.R.C.S. Second edition. London: J. and A. Churchill. 1919. Pp. 372. 8*s.* 6*d.*

THE second edition of this excellent manual has been thoroughly revised: short but adequate sections have been added on the investigation of cases of sudden death, and the procedure to be employed when bacteriological examinations are desired, and brief descriptions of the changes occurring in the commoner tropical diseases have been incorporated in the text. We are glad to see that, in spite of these additions, the size of the book has not been appreciably increased. A work of this character cannot enter into competition with the more elaborate text-books of morbid anatomy, and its distinctive features would have been lost by injudicious expansion. In its present form it is one of the best and most useful units in the pathologist's library, and we can strongly recommend it as a reliable guide in all matters of post-mortem technique.

A SURGICAL HANDBOOK.

For the Use of Students, Practitioners, House Surgeons, and Dressers. By FRANCIS M. CAIRD, M.B., F.R.C.S. Edin., and CHARLES W. CATHCART, M.B., F.R.C.S. Eng. and Edin. Eighteenth edition, with appendix. With 208 illustrations. London: Charles Griffin and Co. 1919. Pp. 364. 8*s.* 6*d.*

THIS familiar volume has been brought up to date by the elimination of many old illustrations and their replacement by new ones, and it has grown by 40 pages. To all those officers who have had occasion during the war to augment their military knowledge by resorting to the "Field Service Manual" this surgical handbook will bring back memories. Just as the Field Service Manual treats of anything from the building of an incinerator to the firing of an 18-pounder gun, so this handbook deals with matters as far apart as the direct transfusion of blood and the cooking of food for the sick-room. It is essentially a book of reference, and lays no claim to any higher function. It has filled that place for many a busy doctor in the past, and will assuredly continue to do so in the future. Its illustrations are very numerous and diagrammatic in their simplicity. The index, which is of vital importance in a volume of this type, is adequate. We recommend it as a useful book for those for whom it is intended.

LEÇONS DE PATHOLOGIE DIGESTIVE.

By M. LOEPER. 4me série. With 34 illustrations. Paris: Masson et Cie. 1919. Pp. 298. 11 francs.

THESE 20 essays on a variety of topics connected with gastro-intestinal medicine range irregularly over a wide field—hyperchlorhydria, flatulence in Graves's disease, sarcoma of stomach, duodenal ulcer, the rectal lesions of dysentery. The author thinks he can establish the existence of a suprarenal dyspepsia and constipation, arising from adrenal insufficiency, which are amenable to specific treatment. An interesting chapter describes the cardio-vascular defects of dysenterics, and the last three essays all deal with the rather neglected nervous apparatus in the walls of the stomach and bowels. Functional disease is recognised, and especial importance is attached to the local implication of ganglia and nerves in dysentery and cancer as the cause of pain; there are some striking illustrations of diseased sympathetic ganglia.

THE WELFARE OF THE SCHOOL CHILD.

By JOSEPH CATES, M.D., D.P.H. English Public Health Series, Vol. VI. Edited by Sir MALCOLM MORRIS, K.C.V.O. London: Cassell and Co. 1919. Pp. 154. 5*s*.

DR. Cates writes in a clear and straightforward style which is well adapted for the wide public to whom this series is addressed. The first part of the book deals with the findings of medical inspection of school children, and is calculated to produce the requisite amount of horripilation in the reader. The final chapters deal with the school building and the school annexe. The latter, which is the offspring of recent solicitude for the welfare of the school child, includes the canteen, the gymnasium, the school baths, the play centre, and the treatment centre. The author writes from the point of view of the medical officer of health of a large industrial town, who is also the school medical officer. The importance of the environment of the school child in the production of ill-health is throughout insisted upon. Dr. Cates writes strongly upon the iniquities of the insanitary privy-midden and the pail-closet. It is to be doubted, however, if these relics of the Middle Ages have in fact that influence in producing malnutrition in children which he ascribes to them.

In contradistinction to the general run of similar books little space is devoted to infectious diseases in relation to schools and scholars. These diseases are treated only in a general way, but the paragraphs dealing with them reveal a breadth of view and a progressive spirit which it is not usual to find in the sanitarian's attitude to this question. Instead of the ostrich-like policy of wholesale exclusion from school, Dr. Cates advocates the attendance even of contacts from houses in which infectious disease exists; and he describes a system of regular supervision and visiting by school nurses which has proved more successful in practice than the older methods of school closure and exclusion.

Dr. Cates writes only of what he knows and therefore with authority. The book, however, has in consequence the defects of its qualities. Many of the public for whom it is intended will search it in vain for any description of, or even allusion to, the various forms of voluntary effort which have been enlisted throughout many progressive areas in schemes for promoting the welfare of the school child. The subject of physical exercises is not adequately dealt with and no guidance is given in regard to such immediate extensions of activity as, for instance, the development of nursery schools. In spite of these serious omissions the work is an admirable exposition of the conditions which exist and of the provision which has been made for the welfare of the school child in a typical manufacturing district; and no doubt if the author had not limited himself to the things of his own experience the book would have lost much of that directness and authenticity which are its most important characteristics.

A DICTIONARY OF TREATMENT.

By Sir WILLIAM WHITLA, M.A., M.D., LL.D., M.P., late Professor of Materia Medica and Therapeutics in Queen's University, Belfast. Sixth edition. London: Baillière, Tindall, and Cox. 1920. Pp. 1083. 25*s*.

THIS work was first published in 1891, and the fact that it has reached its sixth edition is sufficient proof that the efforts of the author in making the book a useful work of reference have met with the success they deserve. The dictionary includes medical and surgical therapeutics, and the present volume has been, as far as possible, brought up to date. The more common affections, which form the great majority of cases in ordinary practice, receive due attention, whilst the rarer maladies, such as sprue and anthrax, are likewise discussed at suitable length.

The amount of space devoted to the treatment of the various diseases is by no means curtailed; for instance, no less than ten pages are occupied with the discussion on the therapeutics of eczema. Functional affections of the heart occupy nearly four pages, whilst the information on valvular diseases of the heart takes up 14 pages, and sound and practical suggestions are made as to the drug treatment of these affections and the general mode of life to be adopted by the patients. The book is a reliable and complete work of reference within the limitations which the author has resolved to observe. It is a dictionary of treatment and not a system of the art and science of medicine.

ROENTGEN INTERPRETATION.

A Manual for Students and Practitioners. By GEORGE W. HOLMES, M.D., Roentgenologist to the Massachusetts General Hospital; and HOWARD E. RUGGLES, M.D., Roentgenologist to the University of California Hospital. With 181 figures. London: Henry Kimpton. 1919. Pp. 211. 15*s*.

THIS volume is a valuable contribution to radiology inasmuch as, unlike many works on the subject, it deals adequately with the most important aspect of radio-diagnosis. The aim of the authors is to provide a general guide to the accurate interpretation of the evidence afforded by X ray methods. They are careful to impress the fact that no book can impart the necessary skill, and that the illustrations given are but types of lesions, or momentary phases of constantly changing and extremely variable processes. Given access to the work of a busy X ray department this book will be of great value to the radiological student, but, of course, a medical training is a necessary prelude to this study. The authors rightly say that: "In attempting to study gross changes by means of shadows a knowledge of pathology is as essential to the roentgenologist as that of anatomy is to the surgeon."

The book is arranged as a series of chapters, each dealing with a special subject, and concludes with a bibliography which, while not complete, is sufficient for the purpose. Some chapters seem rather compressed, but if every section were treated at length the volume would cease to be the convenient, almost pocket companion it now is. Every radiological student should have this book constantly at hand as he is sure to find in it many a useful hint for the elucidation of obscure X ray findings.

JOURNALS.

Journal of Pathology and Bacteriology, Vol. XXIII., No. 1, pp. 1–128, December, 1919.—Experiments on the Action of Unsaturated Fatty Acids and Lipoids on Amylolytic and Hæmolytic Phenomena, by P. Stocks.—A Modified Wassermann Test, by C. Y. Wang. The author mixes loopfuls of unheated serum antigen and sensitised ox corpuscles on a slide and observes the result microscopically; enough blood can be obtained from a fine capillary tubeful. He meets the many objections which will naturally be raised by showing that in a long series of cases tested in parallel with the original Wassermann method his process affords a rather more delicate test. Heating the suspected serum is harmful to the specific reacting substance as well as to complement.—The Biochemical Comparison of *Bacillus sporogenes* and the Reading Bacillus by Quantitative Methods, by J. E. G. Harris.—The Paths of Spread of Bacterial Exotoxins, with Special Reference to Tetanus Toxin, by F. H. Teale and D. Embleton. Tetanus toxin passes from the site of injection to the central nervous system more by way of the perineural lymphatics than along the axis-cylinders; although it is quickly passed from systemic capillaries to connective-tissue spaces it will not pass into the central nervous system from the cerebral capillaries, nor into the cerebro-spinal fluid through the choroid plexus. Tetanus antitoxin cannot enter the central nervous system by way of the blood-vessels, axis-cylinders, or perineural lymphatics, nor from the cerebro-spinal fluid.—Macroscopic Appearances of War-injured Nerves, by S. M. Cone.—The Protozoal Parasites of the Rat, with Special Reference to *Spirochæta icterohæmorrhagiæ*, by A. G. R. Foulerton. A full account of the occurrence of the parasite of spirochætal jaundice (4 times in 101) and *Trypanosoma lewisi* (45 in 123) in London rats, with a useful summary of the present state of knowledge.—A Squamous Epithelioma of the Frontal and Maxillary Sinuses in a Mare, by J. F. D. Tutt.—Hydrogen-Ion Concentration and Antiseptic Potency, with Special Reference to Acridine Compounds, by C. H. Browning, R. Gulbransen, and E. L. Kennaway. Acridine compounds are specially effective in serum, because they do not combine with proteids, and work best at the reaction of body fluids.—Ectopia Cloacæ, by C. Walker.—Obituary of S. G. Scott, the histologist, with a portrait familiar to those who knew him in his laboratory at Oxford.—Spontaneous Nephritis in Rabbits, by J. P. McGowan.—Ganglioneuroma of the Adrenal and Neuroblastoma of the Sympathetic, by M. J. Stewart.—Subacute Liver Atrophy in a Case of Syphilis Treated with Galyl, by M. J. Stewart, C. W. Vining, and J. P. Bibby.—A Starch-splitting Streptothrix found in the Stools in Diabetes, by W. Ford Robertson.—Method of Staining Organisms in Tissues, by G. H. Wilson.—Antiseptic Properties of Acridine and Phenazine Compounds, by C. H. Browning, J. B. Cohen, and R. Gulbransen.—The Small Production of Agglutinins by Mice, by A. E. Boycott.—Effect of X Rays on Susceptibility to Bacterial Infection, by C. H. Browning, R. Gulbransen, and S. Russ. No effect with pneumococci and tubercle bacilli.

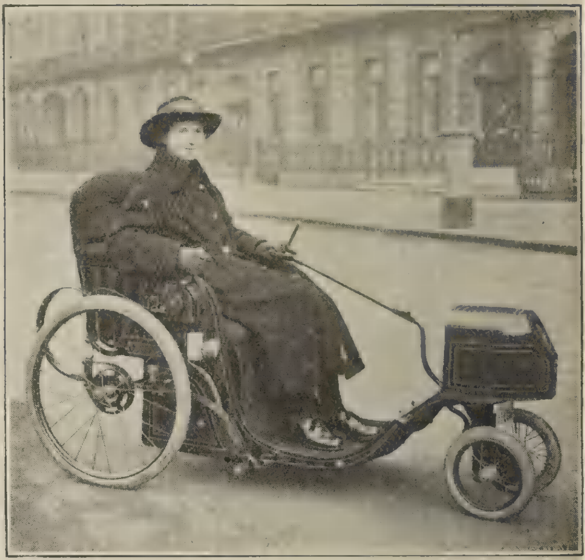
BOOKS OF REFERENCE.

Burdett's Hospitals and Charities, 1919: The Year Book of Philanthropy and Hospital Annual (London: The Scientific Press, Ltd. Pp. 1087. 12*s*. 6*d*. net), which contains a review of everything that concerns hospital administration, medical schools, asylums, convalescent institutions, and nursing establishments, is now so well known and established as a reliable book of reference that it scarcely requires from us any detailed description or commendation. At a time when hospitals are so sorely tried to make ends meet that there is grave danger of State intervention and the abolition of the voluntary system which has been the boast and pride of this country for the past 200 years, Burdett is particularly valuable as showing not only the needs of our healing institutions, but also the enormous volume of succour to the sick poor which they give. This valuable book also contains much useful information in regard to American and colonial hospitals and allied institutions, and we know of no other work of similar scope which is so convenient for reference.—*The Annual Charities Register and Digest* (London: Longmans, Green, and Co. Pp. 584. 5*s*. net), which is now in its twenty-eighth edition, is another well-known work of reference, and is an indispensable handbook to everyone who is interested in the charities in, or available for, the metropolis. Besides containing a review of the year of the financial position of metropolitan charities, detailed information is given of the individual institutions grouped under headings such as blind, deaf and dumb, epileptics, incurables, and so forth; while, under the heading of miscellaneous, societies dealing with social and physical improvement, employment, emigration, and protection of life, and of the helpless are dealt with. Reference is facilitated by a very full index.

New Inventions.

AN ELECTRICALLY DRIVEN BATH CHAIR.

OUR Motor Correspondent writes: An invalid's carriage, comfortable and luxuriously C-spring suspended, which is sure to be appreciated by invalids owing to the fact that it is driven by the occupant and thereby does away with the necessity of an attendant, has been produced by Messrs. J. and A. Carter, of Great Portland-street, London. Twenty-four 4 volt accumulators, each of 36 ampères capacity, placed under the seat, drive a ¼ h.p. electric motor housed under a bonnet over the front axle. The transmission from the motor to the front axle is by helical gearing, well boxed in, with a conveniently placed plug for oiling. The control is by a lever on the driver's right. When this is pulled back it applies a band brake to the right rear wheel. Pushing the lever forward and depressing a button releases the brake and switches on the power, which is full on with the handle fully advanced. By this means any speed from a mere crawl up to five miles an hour can be obtained. Sufficient power, which is ample to ascend any incline, is carried for a run of about 20 miles. An accessible switch permits reversing at any speed. There is an additional brake, controlled by a lever on the left hand and acting on the left rear wheel. The front wheels have 12 × 1½ Dunlop pneumatic tyres, the rear 26 × 2 Dunlop pneumatic grooved motor-cycle tyres. The steering is of the ordinary bath-chair type, and seems particularly easy. On the floor facing the driver is a voltmeter and a plug for charging the batteries; a mileage recorder is also attached. The weight empty is 2¾ cwt. The machine is simplicity itself, and any patient with the use of his arms can manipulate it, and take a run at any speed up to five miles an hour.



The simplicity and ease of control greatly appealed to the writer, as, after a moment's explanation, he was able to manipulate the chair in and out among crowds of furniture in the showrooms, advancing and reversing at will. For ascertaining that there is sufficient power in the accumulators for a trip, it would be as well if an amptmeter as well as a voltmeter was fitted. A voltmeter may register almost the full voltage until the accumulators are nearly run out. Legally, the chair must be registered as a motor-car, carry number plates, and pay an annual motor-carriage licence. The driver, too, must have a driver's licence. It seems rather an anomaly that an invalid carriage, with a speed-limit of five miles an hour, should be thus penalised. The matter is, I understand, being represented to a traffic committee, now sitting, with a view to obtaining exemption of self-propelled bath chairs from regulations which it seems absurd to apply to such vehicles.

THE LANCET.

LONDON: SATURDAY, JANUARY 3, 1920.

The Coöperation of the Future.

THE opening of a New Year is a convenient date in which to register the experiences of the past and to determine upon the activities of the future, but such revisions and provisions will not have their full value, and may, indeed, betray us into error, if there is any tendency to regard the separate years as isolated periods rather than as arbitrary divisions of continuous time. No one really thinks that the embarrassments of 1919 have disappeared with the dawn of 1920, or that we can start with a slate free from the errors whose sequence remains, because we have determined that no such errors shall occur again. What we can decide at any moment is that the legacy charges of the past shall be paid in full with as much promptitude as possible, so that the assets which remain shall fructify in due season, and so that our future enterprises shall have free play and good chances of successful issue. And New Year's Day is a good time to register and act upon that decision, because it is a date upon which other people are likely to take the same course. The very general manner in which civilised persons regard the beginning of the year as an opportunity for stock-taking leads to coöperative effort making for human progress. The moral for the medical profession is exposed.

The anxious phase through which the calling of medicine is now passing makes it particularly necessary that those who follow it should face the problems of their professional life in a coöperative spirit, recognising that certain of the changes that will surely be brought about in our careers are quite commendable, and that others, if repugnant on the surface, may none the less be socially right in their working; and recognising, also, that some of the innovations may be found not to have the fortunate tendency attributed to them by their sponsors, when common steps to remedy the ill should be arranged. We have to regard the legislation for National Insurance against sickness, and its results, as a phase in a consecutive story—the story of the development of medical practice; and we have to think clearly, as a body of men who have been trained so to think, which of the unfortunate conditions of medical practice are being removed by new legislation and which are being confirmed into our daily work. We must consider how to mitigate these latter, how to assist the promises of scientific progress to develop under impending regulations, and how to ensure that faults in these regulations will be removed. Panel practice is an expression of the desire of the people to enjoy the ministrations of medicine in a full measure; unless our rulers had known that popular support was behind the national insurance legislation no such enactments would have ensued. But all medical practice has this same origin—it all springs from the natural wish of man to be free from disease—so that no separation between panel practice and other medical practice is possible in the logical mind. There is one common policy before the medical profession now as ever, and that is to ensure that the conditions of medical practice should be such that the nation may obtain from our efforts its full scientific value. This can only happen if the whole of our body is united not only in the altruistic desire to do good, and not only in the reasonable determination to obtain adequate remuneration for services rendered to the public, but also in the furtherance of detailed plans of coöperative practice whereby the care of the sick becomes a homogeneous whole.

It is fine testimony to the influential evolution of medicine that day by day a medical side to common affairs makes its appearance and draws from intelligent people acknowledgment of the spread of our science. This diffused dependence upon medicine is as good for our calling as it is for the world at large, for medicine is essentially one of the branches of human learning that requires the coöperation of humanity if it is to exercise its beneficent force. To-day medicine bids fair to take the place which classical learning occupied in the sixteenth century among the humanists who distributed the stores of classical literature placed at the disposal of the world by the revival of learning, seeing in them the food and instruction necessary for a long journey forward in civilisation. We medical men have to regard ourselves as the almoners of vast scientific blessings. It is our duty to join our forces so that for all classes of the population the best help we can provide is available; and whereas we know our weakness and our strength more intimately than any Government department can know them, it is essential that the methods under which those forces are marshalled should be those which experience of practice tells us will lead to the best service.

◆

First Principles in Thoracic Surgery.

UP to the end of the year 1916 the expectant method of treating wounds which opened the pleural cavity was in vogue, and this resulted, speaking generally, in a number of deaths, a proportion of recoveries after prolonged convalescence, and a considerable residue of cases which made a good recovery and were returned to duty. The serious attempt to apply the general principles of surgery to gunshot wounds of the chest soon showed that it was both practicable and safe to operate in the early stages by opening the thorax widely, removing the larger fragments of metal along with carried-in bone and clothing, and repairing the injured lung, the chest being then closed again. Most innovations are exploited beyond their merits, and there were at first some who claimed that every chest wound should be submitted to operation. The less severe injuries, however—typically those caused by the passage through the chest of a rifle bullet with small entry and exit wounds, without much splintering of ribs and without large hæmothorax—healed with little trouble, while a survey of after-histories showed a large proportion of quick return to duty. On the other hand, it was manifestly necessary to save life by operating on all patients with open sucking wounds of the chest, with extensive ragged wounds of the parietes, or with retention of large foreign bodies which had presumably carried in infected clothing. Between these two extremes lay a large number of cases in which the surgeons might well be in doubt whether to operate or not. Only an elaborate analysis of after-histories could answer this important question, and this was impossible while fighting was going on. It is only now that the appearance of a collection of statistical reports[1] by the Medical Research Committee affords material for at least a tentative answer.

In this valuable brochure of 40 pages are included some notes on penetrating wounds of the chest, by Major W. L. MANN, from No. 3 Canadian C.C.S.; statistics dealing with the operative treatment of chest wounds during the autumn of 1917, by Colonel A. B. SOLTAU and Colonel T. R. ELLIOTT, collected from about 40 C.C.S.'s in the Ypres and Lens salients; and statistics from base hospitals during autumn of 1918, showing after-histories of cases of penetrating gun-shot wounds of the chest transferred from C.C.S.'s, by Colonel W. PASTEUR and Colonel ELLIOTT. Along with these reports should be read an earlier analysis, in the same series, of 600 cases of gunshot wound of the chest, by Dr. J. M. FORTESCUE BRICKDALE, as well as the paper by Dr. J. B. MCDOUGALL, which appeared in our issue of Nov. 29th. The careful reader will then have before him materials for estimating the value of surgical interference in those cases of injury of the chest on which surgical opinion has not yet spoken. Major MANN was recognised as a surgeon of sound judgment who possessed great technical skill. He saw and treated himself at Remy Siding, near Poperinghe, between June, 1916, and November, 1917, the 600 cases which he has followed up. He advises operation in all cases of open thorax, in all cases of infected hæmothorax, and in those instances where the parietal wounds are large and ragged. Operation is not advised when the hæmothorax is unaccompanied by symptoms of infection, distress, or extensive damage to the parietes. His report, in fact, comes down to a recommendation for confining surgical interference to life-saving operations and for treating the rest by expectant methods. The analyses of SOLTAU, PASTEUR, and ELLIOTT alike aim at showing the average results of thoracic surgery as practised by operating surgeons at clearing stations, and the final conclusion runs:—

> "The general incidence of empyemata was not markedly reduced by early operations, and the great value of the new surgical procedure was seen to lie chiefly in its power to save from death men with wounds of such severity that, apart from early operation, they would unquestionably have died outright or succumbed later to an overwhelming infection of the pleura."

The opening-up of the chest has on this showing saved life only in desperate cases, and it has not lessened sepsis in any material degree.

Some courage is required to question the deductions drawn from such figures with every care by able men, but it is nevertheless fair to ask whether figures obtained under very trying conditions convey the correct impression—whether, in fact, they can safely be regarded as standardising the procedure in gunshot wounds of the chest. There is another point. The new thoracic work was only begun at the end of 1916, and was still in its infancy in 1917, when surgeons were groping for the right way to operate and the right cases to choose for operation. In 1918 the fixed front became mobile, and all the conditions of operation were profoundly altered. These are precisely the circumstances under which the personal impression of a particular surgeon may be as just as the highest common factor of a very variable group of workers. And undoubtedly the impression that has remained with many a surgeon personally engaged in looking after chest wounds, is that lives were saved and sepsis was prevented by effective operation upon the right cases at an early stage. This is as much as to say that the principles of surgery, established for wounds of other parts, are applicable to wounds of the chest—a sound principle, and one which will hardly lead the surgeon into error or his patient into danger.

The Medical Report as Popular Educator.

THE preface to the annual report for 1918 of Dr. MEREDITH YOUNG, medical officer of health to the county of Chester, contains a confession of faith as to the function of the medical officer's annual report which is of considerable interest. It is this:—

> ......"Few if any business concerns can be carried on without an annual stock-taking. The medical officer's annual report is his annual report on the stock-taking in life and death, health and disease. From figures which one understands oneself, and which one endeavours to make comprehensible and of interest to others, the medical officer of health can see the leakages of life and health and draw conclusions as to their causation and the effect of measures intended to prevent them, so that more effective propaganda may be devised and worthless methods discarded."

Dr. YOUNG has given a useful reminder of the part which such periodical reports can be made to play in the information and education of the general public, and his remarks might well be adopted as a motto by medical officers of health in preparing their annual reports. The actual duty of the medical officer of health is not to advise the public in his report, but he will be serving his authority usefully if he does so, or supplies his authority with the proper grounds for the sanitary instruction of the public.

---

[1] Statistical Reports, No. 5, on Penetrating Wounds of the Chest. H.M. Stationery Office. Price 1s. 6*d*.

While full recognition must be given to the admirable qualities of many reports issued from time to time by busy medical officers of health, it cannot be denied that there is also a number of somewhat indifferent and uninspiring reports which fall short of any standard that would have educational influence. What causes underlie the comparative ineffectiveness of this latter group? First, there are defects in exposition. Of late it has been realised, to a constantly increasing extent, that to reach the average man the principles of preventive medicine must be popularised; thus national healthiness may be reached by educating the layman in the avoidance of the beginnings of disease. The authority of the medical officer of health is directly a lay one, though he is also an officer of the State, and the instruction of laymen by medical men implies the depolarisation—to use WENDELL HOLMES'S analogy—of medical technicalities and their translation into the vulgar tongue. This is a difficult art to which it is not the lot of all medical men to attain. Sir GEORGE NEWMAN'S recent report to the Minister of Health, giving an outline of the practice of preventive medicine, may be quoted in happy illustration of the art at its best, and excellent examples could be adduced among the annual reports of medical officers of health. But many medical men find it very hard to give an exact message in the vulgar tongue, and the experience of medical witnesses in a court of law proves that sometimes this is quite impossible.

Lack of teaching instinct is not the only cause of failure, which in some cases seems to depend on misconception of the purpose of the annual report. Such reports are not merely a record of the past: they should also be a sign-post to the future. Among other reasons for an uninspired annual statement are: Lack of willingness to arouse opposition by a ventilation of defects when the medical officer concerned has no security of tenure of his post, and is perhaps only a part-time officer; excess of caution as to giving hostages to fortune by a statement of views; the dead-weight of a parsimonious council which will in some cases not even sanction the cost of printing the report. But the heart of the difficulty is in most cases lack of time. The statistical material must in any large area be prepared by clerks; is the commentary by the medical officer of health to be a mere connecting thread, or is it to be a reasoned deduction from facts? The former course results in a form of report stereotyped from year to year and tending to degenerate into a dreary sequence of tables. Such statistical statements obviously are essential to any business-like presentation of the facts, but it is not every medical officer of health who realises the vital importance of conveying the lesson of his figures to the reader without compelling the latter to seek out the meaning for himself. Were it an instruction to medical officers of health that all tabular matter should be replaced by a written statement of its purport, the loss might be counterbalanced by an increased appreciation of the underlying meaning, but this would be an undesirable and impossible proceeding. The many medical officers who now present in the body of their reports a popular statement of public health progress, relegating the statistical matter to appendices, have probably hit upon the best course. The difficulties in the production of the perfect report are varied and obvious; we register appreciation of those many reports in which these difficulties have been triumphantly mastered, rather than grumble at those which do not come up to the ideal. But every dull and incomprehensible annual report from a medical officer of health represents a missed opportunity of educating his authority and his community.

◆

William Osler.

WILLIAM OSLER was the greatest personality in the medical world at the time of his death. By his scientific attainments he had earned a place in the first rank; and that place he adorned by a keen cosmopolitan knowledge of men and things, and by large literary activities which ranged through clinical medicine and every side of scientific education, and included philosophical and biographical essays and humorous disquisitions. Wherever his pen travelled the subject was illuminated by clear thought, accurate knowledge of literary predecessors, classical accomplishment, playful wit, and the most deep and honest charity. He was a great physician, a great professor, and a great author. Apart from the tragic stroke dealt him by the war, when he lost his only son, his life was the happiest one conceivable, for he reached his position on no grounds whatever save the merits of accomplishment and the force and charm of goodness. His swift successes brought no envy in their track, and his abounding popularity was the outcome of an unfailing and instinctive desire to help all who came to him in the most practical way, without either flattering his beneficiary or laying him under a burdensome sense of obligation. He was an embodiment of the fact that the science of medicine should know no racial tie, but should place itself at the disposal of the world. As first President of the Fellowship of Medicine he was in his element in strengthening the bond between Anglo-Saxon doctors; and when the doctors of Vienna sought our help it was to OSLER that they went first, knowing that he would regard them as members of one great calling. He had the genius of friendship, private and public.

Annotations.

"Ne quid nimis."

A MEDICAL PEER

To Sir Bertrand Dawson there accrues the high distinction of being the first medical man to whom a peerage has been given in acknowledgment purely of professional position. Lister was no longer a practising surgeon when he was summoned to the House of Lords in recognition of the world-wide achievements with which his name is associated; Sir Bertrand Dawson has been awarded a peerage on professional grounds, and in response to the growing feeling that in our Second Chamber there should be representation of all the great sections of the community. As physician to the London Hospital and as dean of the Medical Faculty of the University of London he enters the House of Lords with the highest professional status; he is admittedly in the front rank of our clinicians, he is an expert on medical education, and his public utterances dealing with professional organisation reveal him as one with sound ideals and clear views. He is, moreover, Physician in Ordinary to the King and chairman of the Medical Consultative Council, which forms the link between the medical profession and the Ministry of Health. During the war he served as consulting physician to the Forces. A recognition of the calling of medicine is implied in the great honour which has been done Sir Bertrand Dawson, and upon which we congratulate him heartily.

GERMAN MEDICAL ACHIEVEMENT DURING THE WAR.

IN his introduction[1] to the official German Medical History of the War, which he is editing, Otto von Schjerning gives an enlightening sketch of the work of the Feldsanitätswesen, of which he was chief during the last five years. He begins by remarking on the unwillingness of his countrymen to draw the painful lessons of Germany's fall, and reminding them that the need to climb out of their high buskins has enabled them to gain a correct standpoint for German medicine. The bitter want and deprivation have led to a proper recognition of scientific discovery and to new and unsuspected lines of progress. War has been once more, in the words of Heraclitus, "the father of all things," and it is in chemistry and medicine that pre-eminent progress has been achieved. The actual losses of medical personnel on the German side were comparable to our own. 1325 medical men on active service, or 5·4 per cent. of the total number, are known to have been killed or to have died as a result of their work, 2149 others were wounded non-fatally, and 4673 were "missing." Schjerning goes on to give from year to year the special achievements of medicine in the field, the first and most essential being the 238 hospital trains which plied continuously from front line to base hospital and back again. At first tetanus played great havoc in Northern France, typhoid and dysentery in Champagne and the neighbourhood of Metz; each of these scourges soon yielding to appropriate vaccine or serum treatment. On his recommendation Behring and Röntgen early in the war received the Iron Cross in recognition of discoveries which brought untold saving of life and limb. During the long-drawn-out struggle around Verdun gas œdema became urgent, but it was only in the very last months of the war that an effective serum was obtained to stave off its awful consequences. The interesting fact is noted that no dysentery or typhoid convalescents were ever allowed to return home to spread infection; they were all collected in a great convalescent camp at Spa in Belgium until able to return to the line. Five-days fever, scurvy, hunger œdema, malaria, dengue, spirochætal jaundice are severally noted in the account, leading up to the enormous epidemic of Spanish influenza in 1918. Brussels, Warsaw, and Bucharest are given as the chief centres of venereal infection, but Schjerning records as a great sanitary achievement that these diseases were kept in check throughout the whole campaign, and were, in fact, far less prevalent among the troops than at home. In the last months of war various skin diseases became increasingly prevalent, especially sycosis, and parasitic worms abounded.

Speaking of the work of his own staff, Schjerning praises the great skill shown by those charged with setting up and equipping temporary hospitals. More than 24,000 doctors were, on the average, in the service of the army, 3000 were attached to the Red Cross, and associated with them were 600 dentists and 1800 pharmacists. As the available number of fully qualified men was reduced, medical students were summoned to take their places. Schjerning speaks with enthusiasm of the enhanced knowledge and ability gained on military service, with its enlargement of the field of vision and development of character and courage. A great feature of the medical side of the campaign were the conferences on scientific subjects held in the several army areas. Meetings of specialists from all the fronts discussed such matters as combating typhoid, dysentery, cholera, and tetanus. The surgical congresses at Brussels in 1915 and 1918, and Berlin in 1916, and the medical congress at Warsaw in 1916, added much to the store of medical knowledge. These efforts were rewarded inasmuch as the results of medical care improved from year to year, for in the first year of war 88·7 per cent. of wounded and disabled men returned to the front, in the three following years 91·3, 91·8, and 92·8 respectively. Apart from wounds, tonsillitis and gastric and intestinal disturbances played a leading rôle. Tuberculosis showed in the German army not the slightest indication of increase. Under particular medical advances Schjerning notes the abortive treatment of gonorrhœa with silver preparations, the development of the so-called provocative method in latent malaria, and the employment of cystin preparations in dealing with typhoid carriers. In typhoid disease the introduction of a solid and substantial diet from the second week of illness was attended with marked acceleration in convalescence. Alcoholic mental disease diminished greatly during the war. The surgical lessons of the war have been perpetuated for future generations of medical students in the war museums at the Kaiser Wilhelm's Academies in Berlin, Munich, and Vienna, some 7000 preparations having been made. The opportunity afforded by the battle-field to get a new insight into constitutional pathology was not lost sight of, and the normal structure and function of organs was studied on the still warm body. In this way the exact form of the systolic and diastolic heart, of the contracted and relaxed stomach, of the rugæ of the gastric membrane, of peristalsis in the bowel, and of the relations of rectum to prostate and vesicles was determined. A statistical appendix attached to the paper resumes the volume of the work carried out. It is here recorded that more than 10 million doses of tetanus serum and more than 12½ million doses of small-pox vaccine were given, while anti-typhoid vaccine ran up to a total amount of 103,000 litres and that of cholera serum to 80,000.

---

[1] Die Tätigkeit und die Erfolge der deutschen Feldärzte im Weltkriege, zugleich Einleitung zu dem "Handbuch der ärztlichen Erfahrungen im Weltkriege." Leipzig: J. A. Barth, 1920. Price M. 1.80.

It cannot fail to strike the careful reader of Otto von Schjerning's introductory chapter that the record of medical achievement and of medical sacrifice on the other side of No Man's Land was not widely different from the record with which Sir John Goodwin has familiarised us.

THE TREATMENT OF WAR NEUROSIS.

THE advance which has been made, as a result of experience gained during the war, in the method of treatment for cases of neurasthenia, shell shock, and functional nervous disorders in general has been considerable, for no other form of medical disability has received greater or more intelligent attention. The medical men who have been brought directly into contact with cases of this nature, and whose duty it has been during the war to undertake the care of this class of patient, have learned to appreciate the dangers which attend delay in treatment, while experience has shown that special methods will very generally ensure satisfactory results. The Ministry of Pensions has established neurological hospitals for in-patients and psychotherapy clinics for out-patients where these tried forms of treatment can be applied, but the Ministry feels that full use is not being made of these institutions. Many general practitioners, it is suggested, have cases of war neurosis among their patients which are not benefiting to the full by modern developments in therapeutics. Consequently the Medical Service Department of the Ministry is inviting general practitioners who have cases of war neurosis under their charge to communicate with the Service at 14, Great Smith-street, Westminster, S.W. 1, with regard to any case, even if the condition is not severe, which is not progressing rapidly towards recovery. In a severe case this should always be done, and, where necessary, the Ministry will certainly arrange for treatment at one of its special institutions.

THE RIGHT LEVEL FOR AMPUTATION IN ARTERIO-SCLEROTIC GANGRENE.

Dr. D. N. Eisendrath and Dr. R. B. Bettman have pointed out[1] the error of the majority of surgeons in being guided as to level to amputate by the area of arterio-sclerotic gangrene. Not infrequently the amputation is followed by extensive sloughing of the flaps, and either death from sepsis follows or the opposite limb becomes affected by extension of the thrombosis from the femoral to the iliac artery, and then to the opposite iliac. Dr. Eisendrath and Dr. Bettman felt that the ideal method of choosing the level to amputate would be to expose the femoral artery at the middle of the thigh, and to follow it upwards or downwards until the level was reached at which thrombotic occlusion ceased and distinct pulsation could be observed. This method gave gratifying results in the following case. A man, aged 56 years, was admitted to the Michael Reese Hospital, Chicago, with marked evidence of arterio-sclerosis and gangrene involving the entire dorsum of the foot. Pulsation was absent as high as the upper femoral region. Amputation through the lower third of the thigh by the Gritti-Stokes method was decided on. On exposing the femoral vessels at the middle of the thigh for preliminary ligation they were greatly surprised to find the femoral artery completely occluded by thrombosis. Following the vessel upwards they could not find pulsation until close to Poupart's ligament. Here the artery was ligated just above the occlusion—that is, through the lowermost pulsating portion. Amputation was performed at this level, and the patient, who had been extremely septic, made an uneventful recovery. However, in spite of the high level of amputation, there was moderate gangrene of the skin flaps. Dissection of the arteries of the limb revealed many calcareous areas in the femoral and a firm clot occluding it up to a point close to the femoral canal. The clot was adherent in many places, and extended into the tibial arteries. The veins were normal. Dr. Eisendrath and Dr. Bettman consider that exposure of the femoral artery in order to determine the upper limit of the occlusion is the simplest and most accurate method of deciding on the level of amputation.

MIDWIFERY AND THE UNQUALIFIED MIDWIFE.

IT is common knowledge that the proportion of births attended by midwives tends steadily to rise. In a large number of areas considerably over one-half of the total births are thus attended. In Preston, for example, the medical officer of health, Dr. H. O. Pilkington, in his annual report for 1918, shows 75 per cent. of the births as having been attended by midwives, and only 9 per cent. by medical practitioners, while in St. Helens in the same year Dr. H. J. Cates's annual report shows actually that 99 per cent. of the births were attended by midwives. While this tendency indicates, on the one hand, that patients are likely to be exposed to certain risks which might be avoided by skilled medical attention, it must, on the other, be conceded that there are possible recompenses to the patient. For it is quite arguable that the sickness and mortality from puerperal sepsis may actually be diminished thereby, since the Mother Gamps are now rapidly being hustled out of practice by age, infirmity, and the vigilant hand of the supervising authority, and the newer type of midwife, while of a markedly better stamp and education, is at the same time sufficiently afraid of consequences to shrink from undue interference with Nature's deliberate methods of delivery. She will therefore tend to eliminate that fertile source of dangers and of discomforts—instrumental delivery by practitioners too hurried or too tender-hearted to let natural processes take their course. In many areas the midwife has a serious rival in the completely unqualified handy-woman who assists at confinements for which a doctor has nominally been engaged, but at which he does not attend; so that in fact, though not in law, the woman practises as a midwife without the necessary qualifications. There is pressing need for a remedy of this iniquitous state of affairs. Yet the solution of the problem is confessedly baffling. These women are much in request among the poorest classes for their homely qualities, their stock of hoary wisdom—no less impressive when wrong than when right—their practical experience in their own persons in the production and the rearing of large but usually transitory families. Even when the patients favoured with their attentions come to grief, it is still almost impossible to find a case where the incidents are of such a nature that misbehaviour can be taken into a law court. In two recent instances of ophthalmia neonatorum in one district, the same handy-woman and the same doctor were involved, yet nothing beyond a display of inquisitiveness by the supervising authority towards each was possible, for the claim that the patient had asked the doctor to attend the confinement and the handy-woman to help in the housework, and the further statement that the doctor was prevented from attending and that the woman had therefore helped in the emergency, formed an all-sufficient reply. At present, supervising authorities under the Midwives Act have two main policies—one negative and the other positive. The negative policy is to lie in wait for the flagrant case—how long sought and how infrequently found—in which the evidence is sufficiently blatant for the doubtful issues of trial in a court of law to be faced. This course is both tedious and perilous to the prestige of the supervising authority if the latter fails to win its case; and in any event it does not deal with the root of the matter—the shortage of trained help at fees which the poor can pay. The positive policy is for the supervising authority in its alternative character of county or county borough council, or for other local authorities, by joint or separate action, to provide or to assist in the provision of trained midwives. This policy is being increasingly adopted by the multiplication of district nursing associations, and by the provision of municipal midwives. There can be no doubt that while it tends primarily to put out of action the less well qualified of the existing "bona-fide" midwives, it does also react on the unqualified handy-women who are the present-day replica of the uncontrolled midwife of 20 years ago. At the same time, legal machinery for dealing with the question more easily than is now possible would be a great boon. Practitioners must be brought to realise the unfairness of accepting midwifery cases unless they have a reasonable prospect of fulfilling their engagements. Any laxity in this matter must result in a strong temptation, to put it mildly, on the part of the cynic to look on the arrangement between patient, doctor, and handy-woman as a tacit understanding equivalent to the covering of unqualified practice.

THE VISUAL REQUIREMENTS OF MOTOR DRIVERS.

IN the early months of 1919 a committee was appointed by the Council of British Ophthalmologists to ascertain to what extent the increasing number of street accidents might be due to defective vision on the part of drivers of motor vehicles. The chief problem before the committee was to determine the types of visual defect likely to affect a driver's power of avoiding accidents, and to devise a standard which would not penalise drivers whose visual defect is such as not to interfere with their capacity for driving with safety. The report, which has now been presented, is divided into five parts: the first recapitulating the conditions under which drivers' licences are at present granted; the second giving the number of accidents occasioned in London annually by mechanically propelled vehicles; the third enumerating the various kinds of visual defect in motor drivers from which accidents may arise; the fourth suggesting a scheme of vision testing for licences; and the fifth summarising the recommendations made by the committee. The Council of British Ophthalmologists now recommends that before a licence is granted the applicant should be required to show his ability to steer a motor-car round corners and to avoid obstacles, and before a licence is renewed the applicant should be required to sign a statement that since it was granted he has not suffered from any physical disability likely to interfere with his driving capacity. Further, that a licensed driver with visual defect who meets with an accident attributable to that defect shall be liable to have his licence cancelled or endorsed. The most important recommendation is to the effect that special sight-test certificates of three grades be granted to applicants whose sight has been tested by ophthalmic surgeons appointed for the purpose: Grade A certifying the holder's visual capacity to drive any kind of motor vehicle; Grade B his capacity to drive any vehicle other than a motor omnibus or tramcar; and Grade C his capacity to drive a motor tramcar. The standards for these three certificates are laid down in the report, which will, we believe, be acceptable both to the police authorities and to the men concerned.

THE PRESENCE OF SO-CALLED VITAMINES IN URINE.

Professor Gaglio[1] recently communicated to the Academy of Medicine of Rome the results of some experiments made in conjunction with Dr. Roseo, which tended to show that the administration of 3–4 c.cm. of human urine, slightly concentrated in a water bath, produced identical curative effects with the vitamine extracted by Funk from rice husks in pigeons suffering from artificial beri-beri produced by feeding on polished rice. Even when the animal was reduced by such diet to a condition of extreme gravity, with contraction of the muscles of the neck and opisthotonos, it recovered completely under the influence of urine given two or three times daily. Continuing the administration of rice and urine the animal remained well for some days, but then the nervous symptoms reappeared in a mild degree, and the animal lived longer than controls deprived of this treatment, the attenuated form of the disease lasting for many weeks. If, when the urine had suppressed the nervous symptoms, the diet was modified by the addition of other nutritive substances, such as yolk of egg, the animal completely recovered. In order to put an interpretation on these experiments, it might be argued that the vitamines, which are formed in the organism or which are derived from food, are eliminated by the kidneys. But it is precisely as regards the conception of vitamines themselves that these experiments seem particularly interesting. Vitamines, as we now know, are diffused throughout all kinds of food, more especially vegetables. Funk, who extracted them from rice husks and yeast, found that the more he purified them the less active they became. It would hence seem that there are several substances which have a similar action and perhaps act synergically in the sense that some, in themselves of slight activity, are capable of reinforcing the action of others. On the other hand, many artificial derivatives of pyridine and pyrimidine, and some xanthin derivatives, have been prepared, which have the same remedial action as vitamines in pigeons affected with polyneuritis. If these substances exist almost universally in food, if they can be artificially prepared, and if one can replace another, their specificity cannot be admitted, even while admitting that they represent alimentary principles indispensable to life. As to the nature of these principles, when we consider the plasma which filters through the capillary walls and irrigates the tissue cells, it must be recognised that all substances necessary to life are to be found in it. Now in this plasma, besides proteids, fats, carbohydrates, and mineral salts, there are many nitrogenous organic substances which either come from food or are produced by the metabolic changes of the organism. Such substances have been for a long time known in chemistry as *nitrogenous extractives*, and in food analysis are calculated specially as *non-proteid nitrogen*. These substances have been neglected as regards their function, being considered merely as dregs to be eliminated. But even though they may be dregs in reality, as long as they circulate in the blood they must play an important part as stimulants of nutrition and of the functions of organs. The so-called vitamines considered in this light lose the idea of specificity which has converted them into mysterious substances.

THE ELSIE INGLIS MEMORIAL.

Two names will go down to history associated in the public mind with the ministry of healing during the war along with those of discoverers and of highly placed administrators; they are the names of two women, one a nurse and one a general practitioner. Nurse Edith Cavell's monument is now being erected in one of London's busiest thoroughfares, though it is not as nurse but as patriot that her fame was gained. Dr. Elsie Inglis's memorial is to take the form of furthering two schemes which she had very deeply at heart: the rebuilding of the Hospice for Mothers in Edinburgh for the study of maternal and child welfare by women medical students, and the foundation of a hospital in Serbia with a training school for nurses. The "History of the Scottish Women's Hospitals,"[1] which has just appeared, is dedicated by its compiler, Mrs. Shaw Maclaren, to Dr. Inglis's memory, and is intended to promote the objects of the Elsie Inglis Memorial. The record centres round a personal appreciation of the founder of the Scottish Women's Hospitals from the pen of Miss S. E. S. Mair, the other sections of the book dealing in succession with the work at Royaumont, in Serbia, Russia, and Roumania, among the Serbian refugees in Corsica, at Salonika, and the Calcutta Orthopædic Centre. The story is told almost entirely in the words of the women who did the work, and a very moving and entrancing story it is. Mrs. Maclaren says that it will be the lasting pride of the Scottish women that it was their privilege to contribute more than one of the heroic figures which have emerged from the wreckage left by the war. To us the really astonishing thing in the history of the expedition is not so much the genius of the pioneers, who have arisen when needed at all such critical periods in the world's history, as the average merit of the rank and file of the party, working under conditions without rule or precedent. The prospect before the medical woman is happy in the light of this experience. Note should be taken of the address in London of the National Memorial to Dr. Elsie Inglis—it is 110, Victoria-street, S.W. 1.

ANAEROBIC ORGANISMS.

THE report of the Anaerobe Committee, which we summarise on another page, clears up a number of dark places in the life of the micro-organisms which shun the air. It has always been something of a puzzle to conceive how strict anaerobes, such as *B. tetani*, which live in cultivated soils, can find conditions sufficiently anaerobic to suit their mode of life. Pasteur's original explanation was that the aerobes living in association with anaerobes are able to abstract oxygen quickly enough to create loci of anaerobiosis. Kedrowsky offered the explanation that the aerobes elaborate substances of a special kind which favour the growth of anaerobes, but this view is not in agreement with the facts. That such a special pabulum is unnecessary is shown by the growth of anaerobes in pure culture on media of the same composition as that required for aerobes. Pasteur's view was modified by von Oettingen, who likened the action of aerobes to that of a reducing substance in solution, but this is a small distinction which may be ignored. It may be said that substantially Pasteur's idea still holds the field. The probable chain of events in the life of a sporing anaerobe living under natural conditions is an alternation between the spore and bacillary form with the variation of the oxygen tension in the immediate neighbourhood of the organism.

Can an anaerobic bacterium multiply in a medium completely deprived of oxygen? A great deal of labour has been expended in attempts to answer this question, which is of both philosophical and practical importance. The energy required by cells for the maintenance of life and for the performance of their natural functions is normally obtained from oxidation processes. We know that most bacteria and some animal cells, such as nucleated red blood cells, are able to exist for a time in the absence of oxygen, but their manner of life is generally altered. Thus the mould, *Mucor racemosus*, which burns glucose to CO_2 and water in the presence of oxygen, is unable to carry the process of combustion beyond the stage of alcohol and CO_2 under anaerobic conditions; at the same time the mould undergoes morphological changes. The yeast cell shows the same alteration in its metabolic activity when it is placed in an oxygen-free sugary solution. The energy for growth and function is here obtained from a chemical process which yields something like a twentieth of the energy of that derived from the usual complete oxidation of glucose. It appears, therefore, that in aerobic organisms the cellular mechanisms, by which chemical energy is utilised, are adaptable to reactions other than those which normally occur. The metabolism of anaerobes is of a special kind, and it is of great importance to know whether absolute anaerobiosis is optimal or whether a very low oxygen tension is necessary for maximum growth. The technical difficulties involved in the solution of the problem are very great; for example, the oxygen condensed in an excessively thin film on the surface of glass cannot be neglected. Noguchi, in his work on the cultivation of the *Treponema pallidum*, used a perfectly air-tight desiccator, which was evacuated under a pump, washed free of air by means of a stream of pure hydrogen, evacuated again, and the process repeated until the gas in the desiccator was unable to darken a clear solution of pyrogallol in caustic soda. By means of such methods sufficient evidence has been accumulated to show that the strict anaerobes can grow and divide under perfectly anaerobic conditions, but most observers have concluded that a certain minute amount of oxygen is necessary for optimum growth in which the oxygen takes part. The general rule may be laid down that there are no sharp lines dividing organisms into aerobes and anaerobes. Most bacteria are able to exist comfortably over a wide range of oxygen tensions. The aerobes are adapted for growth in an atmosphere containing oxygen in a percentage approaching that of air; the anaerobic bacteria vary in their repugnance to oxygen within limits ranging from 0 to about 20 mm. tension.

HOUSING AND PLANNING STANDARDS.

THE medical officer of health who wishes to know his own legal status and duties as a sanitary officer, and in addition those of the local authorities with whom he coöperates, will find the law on these matters clearly and adequately expounded in the new edition of Mr. W. A. Willis's volume on housing.[1] He will also need to possess the latest Memorandum issued by the Ministry of Health,[2] which deals, not only with laws and regulations, but also with the policy to be adopted in carrying them out. Financial assistance is available under the Government's scheme for the demolition of unhealthy areas, as well as for the construction of new houses. The general policy to be adopted towards unhealthy areas is "hasten slowly." Imperfect houses are to be made fit for habitation even if they cannot be made desirable. By the removal of a few houses, the lighting and ventilation of those that remain may be greatly benefited. The standards of fitness are briefly enumerated, those at the head of the list being held to be generally the more essential.

> The house must be (1) free from serious dampness; (2) satisfactorily lighted and ventilated; (3) properly drained and provided with adequate sanitary conveniences, and with a sink and suitable arrangements for disposing of slop water; and (4) in good general repair; and should have (5) a satisfactory water-supply; (6) adequate washing accommodation; (7) adequate facilities for preparing and cooking food; and (8) a well-ventilated store for food.

The last sentence in the chapter on standards illustrates the caution with which the Ministry of Health moves towards demolishing that which it finds it so difficult to create: "Cleanliness and freedom from vermin should be secured; a house continuously and seriously infested with vermin may warrant a closing order." The third section of the memorandum may be accurately described as a chapter on the standards of planning and architecture. It is laid down that there should be a small playground for the use particularly of young children within about half a mile and a recreation ground of moderate size within about a mile of every dwelling, experience having shown that the use by children of open spaces beyond these distances is generally slight. For tenement buildings, where owing to density of population this method of housing is permissible, it is laid down on the triple score of health, amenity, and cost, that the height should never exceed three storeys. It is the sad experience of cities with tall picturesque buildings that the young children who live in the upper storeys are kept indoors to an extent detrimental to their vigour and healthful growth. In a circular letter appended to the Memorandum Dr. Addison solicits the help of the county medical officers of health in obtaining a regional housing survey, and gives the welcome information that the medical staff at the Ministry is being strengthened to cope effectively with the many questions relating to housing.

THE RECENT PARLIAMENTARY SESSION.

ON Tuesday afternoon, Dec. 23rd, a Royal Commission gave assent to a number of legislative measures in which the medical profession is keenly interested. Among the Acts which then received the Royal Assent were the Mental Deficiency and Lunacy (Amendment) Act, the Nurses' Registration Act, the Nurses' Registration (Scotland) Act, and the Nurses' Registration (Ireland) Act. In the King's speech occurred the following paragraph:

> I have also assented to Bills for the establishment of the Ministry of Health in England and a Board of Health in Scotland and a Council of Health in Ireland. I anticipate that, when they are in full working order, they will prove invaluable in coördinating and improving the service of the health of the people.

Parliament stands prorogued until Feb. 10th.

OCCUPATIONAL ULCERS.

TWO new conditions have been made notifiable under the Factory and Workshop Act of 1901. One of these is the epitheliomatous ulceration due to tar, pitch, bitumen, mineral oil, paraffin, or any compound, product, or residue of any of these substances; and the other is chrome ulceration, due to chromic acid or bichromate of potassium, sodium, or ammonium, or any preparation of these substances. In industrial employment ulceration of the skin is not infrequently set up by the substances handled. Under appropriate treatment, at no matter what age, such ulceration usually heals quickly, and should it recur will again heal with rest and treatment. In the case of those handling tar and similar substances, however, especially when the workers are over 35 years of age and have worked for many years at a particular operation, the ulceration following on the skin irritation set up may not heal, but spread over a larger surface. This form of ulceration, which occurs with relative frequency on the scrotum, is then to be regarded as epitheliomatous, and is to be notified as such to the Chief Inspector of Factories at the Home Office. When chrome compounds and their solutions remain in contact with the broken skin, and sometimes even with a very sensitive skin in the absence of an obvious broken surface, they give rise either to a general eczematous ulceration or a circumscribed ulcer known as a "chrome hole." Both these conditions, when definitely ulcerative, are now notifiable. Recurring attacks of either epitheliomatous or chrome ulceration should also be reported when a different part of the body is attacked.

THE PREVENTION OF INFLUENZA.

In view of the possibility of a further outbreak of influenza this winter the Ministry of Health has issued a circular (No. 50) and a memorandum (No. 2 Med.) dealing with the measures which should be taken for preventing the spread of infection and for lessening mortality from the disease. Influenza spreads with such extreme rapidity that arrangements for dealing with outbreaks require to be planned out in considerable detail, and the part to be played by each officer determined and understood in advance. It is especially desirable to make provision for sufficient nurses to be immediately available when their services are required, and any sanitary authority may provide medical and nursing assistance for its poorer inhabitants, including the dispensing of doctors' prescriptions. The chief novelty is the gratuitous supply of anti-influenza vaccine as a formula containing a larger proportion of Pfeiffer's bacillus than formerly. It is represented as a vaccine against secondary complications, of which the degree of utility is not yet established, but which should be used now if it is used at all, not kept until a new wave is on us. Supplies of this prophylactic vaccine will be furnished to medical officers of health for distribution to all medical practitioners in their area who desire it, and its systematic employment would throw light upon a very dark corner of epidemic disease. Applications for vaccine in quantity should be addressed to the Government Lymph Establishment, Colindale Avenue, The Hyde, London, N.W. 9, stating the quantity required. The Ministry of Health lays great stress on the publication by each authority of full information respecting the facilities provided for assisting persons suffering from influenza and on the preparation of leaflets, posters, and other educational methods, setting out the precautions to be adopted to minimise the risk of infection and complications.

At the end of the memorandum a schedule is given of the ten points to be carefully considered by every sanitary authority.

1. The appointment by the authority of a small emergency committee, to whom, with the medical officer of health, should be delegated full powers to act and incur necessary expenditure.
2. Medical practitioners and any voluntary health workers in the district to be consulted through their respective local organisations and their coöperation invited in determining the practical methods to be adopted.
3. A scheme as regards the provision of nursing and other assistance to families stricken with influenza to be formulated, such scheme to be carried out under the direction of the medical officer of health.
4. Division of the town or district for this purpose into areas, to each of which one or more trained nurses are allotted for domiciliary nursing, the nurses to act in regard to individual patients solely under the direction of the medical practitioner in charge of the case.
5. Women to be enlisted as "home helps," to assist with cooking, care of children, and ordinary domestic work. Inquiries to be made to ascertain where such assistance is most urgently needed.
6. Utilisation to the best advantage of health visitors and other members of the staff of the authority and of institutions under the control of the Council; improvisation of temporary creches and of special kitchens in which food and invalid diet can be prepared.
7. Allocation to influenza patients of one or more wards in the isolation hospital or in some other available and suitable emergency hospital.
8. Issue of notices and leaflets to the public.
9. Prevention or mitigation of overcrowding, and securing adequate ventilation in public buildings or conveyances under the control of the Council.
10. School closure may be specially useful in rural and smaller urban districts.

These are measures which, in the opinion of the Ministry of Health, may in the aggregate reduce the opportunities of exposure to infection. By thus helping to space out the epidemic, something may be done to prevent serious dislocation of the ordinary life of the community—a dislocation which itself increases the danger by making proper care of the sick impossible. The most important services which can be rendered, however, consist in the organisation of the available nursing service and the provision of assistance to influenza-stricken households.

THE CHINA MEDICAL BOARD.

No larger field for medical education is to be found anywhere in the world than that of China, with its population of 300 or 400 millions. To train the necessary doctors for China might fitly be described as a Herculean labour. It is not wonderful that what is probably the largest single fortune ever amassed in history should be seeking its outlet in this field. We welcome the work for this object undertaken by the Rockefeller Foundation (61, Broadway, New York), which has just received a further donation of 50 million dollars from the "Oil King." The fourth annual report, from Jan. 1st to Dec. 31st, 1918, lies before us. Peking is the centre of their operations, and they have wisely joined forces with the only other unofficial body undertaking the task in any large way—namely, the doctors who have gone to China in connexion with the missionary societies of England and America. Some 5 million dollars are being put into land, buildings, and equipment in Peking, and a staff of over 70 persons are associated with the Union Medical School there. The larger number of these seem to have high qualifications and good experience. To read through the list gives the impression that the China Medical Board is taking its task seriously. In order to secure a constant stream of well-prepared students, the board has appreciated the necessity for helping a number of institutions where preliminary teaching is given, and no less than 19 hospitals and three other medical schools have been assisted by grants. Another most important service rendered is the granting of scholarships for post-graduate and research work to missionary doctors on furlough. In this way 35 medical missionaries and nurses have been helped and 11 Chinese doctors, besides others, such as students and pharmacists. It is well to see great wealth being spent with discretion and largeness of vision to help in alleviating human suffering. The means by which such wealth has been accumulated, and the value of the system that makes its accumulation possible, may be open to criticism, but there can be no doubt that, once accumulated, the method of disposal which the Rockefeller Foundation has conceived and is carrying out is of good augury for the future.

THE IRISH PUBLIC HEALTH COUNCIL.

A well-informed Irish correspondent writes:—There is a growing feeling among the public, as well as in the medical profession, that the Irish Public Health Council would be wiser if they put their cards on the table and showed clearly in what direction their deliberations were tending. Rumours differ as to the position of affairs in the Council, with the result that an atmosphere of suspicion is being created, inimical alike to clear thinking and practical action. In the last number of the *Journal of the Irish Medical Association* there is a note to the effect that the members of the Council propose to have a conference with the Irish Medical Committee so as to attempt to decide who, under the new scheme, will receive free medical attendance. This will raise several questions:—(1) What is to be the solution of the Poor-law medical question with such antagonistic elements as the unfortunate dispensary medical officers (who feel very dissatisfied with the support given them in the past by the central authority—the Irish Local Government Board) and their masters, the guardians, whose chief object is to keep down taxation? (2) How will the union and county infirmaries and the town and city hospitals be affected by such a plan? (3) What is to be the position of the insured, even in the truncated scheme in force in Ireland, so distasteful to the public, to the insured (in constant quarrel with the societies), and to the panel doctors? (4) What about the housing question—the bed-rock of public health—and the milk-supply? (5) Are new maternity homes to be erected over the country? A large body of the medical profession and public see that the schemes recently put in force by the authority of the Local Government Board to cope with tuberculosis, with infantile mortality, and with the spread of infectious epidemics have failed. The only result seems to be greater expenditure than ever of public money, with no concomitant lowering of the mortality and with no diminution in the prevalence of preventable disease. These people are asking, Is there to be in Ireland a State public health scheme, and, if so, is it to be of a part- or of a whole-time nature? Ireland never was so financially prosperous as at present, and as a result young men and women are crowding the medical schools, their parents believing that there will be soon an immense number of well-paid medical officials administering a State Medical Service. Young men recently qualified are also coming back to the universities and schools to prepare for a public health qualification. One thing is clear, no Irish Medical Committee will attempt to advise an Irish Public Health Council on such difficult questions as those I have set out until an expression of opinion from the whole medical profession has been obtained. If the Irish Public Health Council is to make any progress they must state openly what measure of public health they propose to suggest for Ireland, and they must remember that it is the medical profession who will have to carry it out, and with whom its success or failure rests.

INDEX TO "THE LANCET," VOL. II., 1919.

THE Index and Title-page to Vol. II., 1919, which was completed with the issue of Dec. 27th, will be published in THE LANCET shortly.

THE DYING-OUT OF NATIVE RACES.

BY W. H. R. RIVERS, M.D., F.R.S.

THE death of peoples is a subject peculiarly fitted for the consideration of an Institute of Public Health. Just as it is the business of medicine to discover why certain members of a community fail to last out the usual span of life or live on in an enfeebled state, so is it the business of public health to discover the causes which interfere with the vigour and vitality of peoples. It is well that such an institute as this should not merely attend to the factors—material, mental, and social—which influence the health of its own community, but should extend the field of its inquiries even to the study of widely different races. In the fate of those unfortunate peoples who have gone under in the struggle for existence, or are tending to this end, we have only an extreme case of a process which it is the aim and business of public health to avert. My object to-day is to inquire into the causes which are producing the extinction of a people for whose welfare this country has made itself responsible.

A lecture concerning disease and death usually takes one of two forms. It may attempt to give a complete account of some subject, the systematic lecture of the schools, or it may take the form known as clinical, in which a patient who illustrates some special feature or features of interest is brought before the audience and made the text by means of which the lecturer may bring forward matter for instruction. When I first undertook to give this lecture I thought of dealing with the subject in the more systematic way, and was preparing a survey of the world and of the causes which are leading to decrease of population here and its growth there. It occurred to me, however, that in the short time at our disposal I could do more justice to the subject if I chose the method of the clinical lecturer and brought before you a special patient, one, I am afraid, sick almost unto death, through whom I can illustrate some of the more salient facts to which I wish to direct your attention. I cannot, as they would at St. Bartholomew's or St. Thomas's, bring the patient before you so that you can see for yourselves the ravages of disease and hear with your own ears the complaints of the sufferer. I must be content with the attempt to bring before you in imagination the people of the islands of Melanesia, whom I have chosen as the patient of this clinical lecture.

Diversity in Physical Type and Language and Customs in Neighbouring Tribes.

If you will look at the map of the Pacific you will see to the east of Australia, extending south-eastwards from New Guinea, a long chain of islands beginning with New Britain and New Ireland, passing through the Solomons and New Hebrides, down to the Loyalty Islands and New Caledonia. The many islands of this prolonged archipelago are inhabited by a people who were almost certainly of original negrito or pygmy stock, among whom there have come at various times the immigrant bands, allied to ourselves, who, farther to the east, have peopled the islands of Polynesia. These immigrant peoples, differing widely in physical appearance from the original inhabitants, settled in varying numbers in different groups of islands, so that there has been produced a high degree of physical diversity of the people. Though all show the negroid characters of the indigenous inhabitants, they vary greatly in colour of the skin, form of the nose, and curliness of the hair, the features which especially distinguish the black from the white division of mankind. So great is the physical diversity thus produced that when time has accustomed the eye to discern the differences, they are seen to be quite as great as those which in our own continent distinguish the tall blonde Scandinavian from the short swarthy type of Spaniard or Italian.

Corresponding with this physical variety there is an even higher degree of linguistic and cultural diversity.

---

[1] A lecture delivered at the Royal Institute of Public Health on May 22nd, 1918.

Though most of the languages belong to one family, here and there, in Fila and Meli, in Bellona and Sikaiana, we find speakers of the widely different though related Polynesian tongue, while in a few cases, such as Savo and Vella Lavella in the Solomons, are found examples of a language belonging to a family which differs as widely from the rest as Magyar or Finnish differ from the Aryan languages of Europe. Comparison with Europe, however, wholly fails to do justice to the Melanesian diversity. Within an island no larger than the Isle of Wight may be found three languages differing from one another as greatly as any three languages of Europe, while dialectical differences are found within a space smaller than the average English parish.

Accompanying this linguistic diversity is an immense variety of custom and institution. Hardly any of the strange human customs which have excited the curiosity and wonder of travellers fail to show their presence among this people, while forms of social organisation and of marriage unknown elsewhere are found among them. Here again the diversity is very great. In one island typical totemism occurs; in another, not far removed, no trace of this form of social organisation exists. One set of islands is altogether dominated by an organisation with many similarities to the secret societies of Europe, while in another no trace of them nor any tradition of their presence in the past is found. In one district there exists a special form of warfare with the sole object of capturing human heads as offerings to the dead, while elsewhere are peaceful people who only resort to war, and then only of a largely ceremonial character, on the occasion of certain social offences, such as homicide or rape. The one feature which is common to all is the permeation of social custom by a firm faith in the reality of the life after death and in the influence of the dead upon the living, a belief revealing itself in countless rites of prayer and propitiation accompanying almost every act of their daily lives.

Effect of Communications with the Civilised World.

Among these lowly peoples, simple and yet full of interest, there came first the brief visits of the Spanish explorers of the sixteenth century, followed by those of the French and British navigators, including Captain Cook. Then followed the occasional visits of a whaler, and the more frequent and prolonged excursions of hunters for sandal-wood. These were followed by settlers, who brought to them the goods of other lands in exchange for their coconut, pearl-shell, and ivory-nuts. With the calico and other useful goods they brought not only the relatively harmless tobacco, but also alcohol and firearms. At the same time there came among them men and women whose object it was to wean them from the customs and beliefs of their fathers and replace them by others of a very different kind.

In addition to the means of death in the form of firearms brought with them by their visitors, there came also the far more deadly diseases, which swept many out of existence and enfeebled the vitality of those who were left. Following the coming of these various influences from without, the numbers of the people so rapidly declined that now, less than a century after the first settlement of Europeans, there are islands, once full of life and vigour, which are either wholly unpeopled or show a miserable remnant to tell the tale of their misfortunes.

It is intended to publish shortly, under the auspices of the Melanesian Mission, an account of the decrease of the population, with a discussion of its causes. I must be content here to give you a few examples from my own observation. In many islands of the New Hebrides the population has practically disappeared. The large island of Fate (Sandwich Island) once had an extensive population spread over the whole island, but when I was there four years ago I could not discover that there were any survivors of the people of the interior, all the existing inhabitants living on a few small islands on its coasts. Further north, the shores of the island of Aore are strewn with sherds of the old native pottery, showing the former presence of a considerable population, but I was told that there are now only three surviving inhabitants. In Espiritu Santo, usually known as Santo, the largest island of the New Hebrides, the inhabitants of several villages on the western coast have entirely disappeared, and their place is taken by a few wretched people who have moved down from the interior.

At the southern end of the island the people of Vulua 20 years ago numbered at least 200, according to the statement of the Rev. J. G. Bowie, the missionary of the district. Now there is only a mere handful of miserable people collected together in one small village, fully conscious that they are the last dying remnant of a once happy and prosperous tribe.

The same story holds good of the Banks and Torres Islands to the north, the destruction having been especially great in the latter group. In the Santa Cruz group, large islands which are said to have been well peopled are now uninhabited, the decline here having been especially great during the last few years. In the Solomon Islands, the tale is less pitiful, but here also the population of many islands is diminishing so rapidly that unless something is done to stay the decline, it will soon share the fate which has already overtaken so many parts of the New Hebrides.

Rapidity of Decline.

The rapidity of the decay at the present time has been brought home to myself very closely by two instances which, though of no great value as evidence, may yet be cited in illustration.

During a visit in 1908 I gained a large amount of valuable information from two men, fairly young and apparently full of life and vigour, one a Polynesian living in Melanesia, the other a native of the Banks Islands. I looked forward to their help in future visits to their islands, but before I had had time to record the knowledge they had shared with me I heard that both were dead. In 1914 I was again in Melanesia and obtained from a still younger native a most important account of a district in the island of Ambrim, whose people had been almost entirely uprooted and destroyed by a volcanic catastrophe. Before I have been able to put this fragment of vanishing knowledge upon record I hear that the witness is already dead, a victim to the scourge of dysentery.

Analysis of Causes of Decline.

Having given this brief sketch of the people of Melanesia and of their impending fate, I shall now attempt an analysis of the causes to which their decline is due and consider measures by which a mortal ending of the disease may even yet be averted.

I will begin with one group of factors which has been frequently brought forward in explanation of the decline of population. It has been supposed that the Melanesians were already a dying people before the European invasion, and that their decline was due to faults inherent in their own culture. In the first place, there is no evidence of any value that the people were decreasing in number before the settlement of Europeans. It may be true that here and there the people already showed some signs of diminution on the arrival of the missionaries, to whom we chiefly owe these reasons. It must be remembered, however, that the people had already been subject for many years to certain European influences, and those of a far from harmless kind.

When these apologists for the effects of their own civilisation give reasons for the supposed original decadence these often bear their own refutation on the face. Thus, one writer blames the heathen custom of polygamy, but in the same paragraph states that the practice is confined to the few. As if a custom confined to the few could ever be the cause of the dying out of a whole people. As a matter of fact, the polygamy of Melanesia is very different from that of Africa, being so exceptional, and the number of wives so small, as to have no appreciable influence upon the people, whether for good or evil.

Another cause which has been put forward is the special kind of consanguineous union usually known as the cross-cousin marriage. This is a marriage between the children of a brother and sister which takes place habitually, while marriage between the children of two brothers or of two sisters is strictly forbidden. This subject was fully investigated by the Commission which, more than 20 years ago, inquired into the decrease of the native population of Fiji. In their report,[2] which forms a storehouse of most valuable facts concerning our topic of to-day, it is shown conclusively that this factor had not contributed towards Fijian decadence, but rather that these consanguineous marriages were more fruitful than marriage between wholly unrelated persons.

I shall deal presently with native customs in relation to our subject, and hope to show that it is rather the indiscriminate and undiscriminating interference with them which stands forth prominently among the causes of decay.

In turning to the real causes of the decrease of population in Melanesia, it is necessary to bear in mind the double nature of fluctuation in population which is fully recognised among ourselves. Diminution of population may be due either to increase of death-rate or decrease of birth-rate, or to both combined. I shall bring forward definite evidence to show that it is necessary to distinguish between these two factors in Melanesia.

Influences increasing the Death-rate.

I will begin with the group of causes which has hitherto chiefly attracted attention, the causes, immediate and remote, of increase of the death-rate.

In a subject in which we shall find little on which to pride ourselves it is satisfactory to be able to exclude one cause which has contributed in so small measure to the decay of native races in other parts of the world. There has been no deliberate attempt to exterminate the people such as has disgraced the history of our relations with regions more suited to European habitation than the sweltering and unhealthy islands of Melanesia. The injurious influences due to European rulers and settlers have been unwitting. Owing to the need for the labour of those accustomed to the tropics it has always been in the interests of the settlers that the native population shall be alive and healthy. In so far as native decay is due to European influence we have to lay the blame on ignorance and prejudice, not on any deliberate wish to destroy.

Disease.—In considering the death of a people, as of an individual, it is natural to think first of disease. Disease is the name we give to a group of processes by which the size of a population is adapted to the needs and demands of its environment. It is one of the means by which the size of a population is adjusted so as to enable it best to utilise the available means of subsistence. Before the arrival of Europeans Melanesia had its own diseases, by means of which Nature helped to keep the population within bounds. Everything goes to show that the population of Melanesia was well within the limits which the country was capable of supporting, but it is not so certain that it was far within this capacity in relation to the very simple means the people possessed for exploiting its resources. So far as we can tell, there had been set up a state of equilibrium between the size of the population and the resources of the country. All our recent knowledge goes to show that the diseases due to infective parasites tend to set up a state of tolerance and habituation which renders a people less prone to succumb to their ravages, and there is no reason to suppose that Melanesia was any exception in this respect. Thus the people are largely habituated to the malaria which certainly existed among them before the coming of European influence.

Into this community thus adapted to the infective agents of their own country the invaders brought a number of new diseases—measles, dysentery, probably tubercle and influenza, and last but, unfortunately, far from least potent, venereal disease. These maladies had effects far more severe than those they bring upon ourselves, partly because they found a virgin soil, partly because the native therapeutic ideas were not adapted to the new influences, so that remedies were often used which actually increased their harmfulness. Many of these introduced diseases are still drawing a large toll on the numbers and energies of the people, the two which seem to be exerting the most steady influence, so far as my observations show, being dysentery and tubercle.

Alcohol.—A second group of introduced causes of destruction is composed of what may be called the social poisons, such as alcohol and opium. Though it is possible that the people use tobacco somewhat to excess, the only poison which needs to be considered in Melanesia is alcohol. In certain parts of Melanesia there is no question that it has exerted in the past, and is still exerting, a most deleterious influence, but it is satisfactory to be able to say that its noxious influence has been reduced to negligible importance in those parts of the archipelago which are wholly subject to British rule, where it is penal to sell or give alcohol to a native.

Firearms.—A third direct cause of increase of the death-rate is the introduction of firearms, by means of which the comparatively harmless warfare of the natives is given a far more deadly turn, but this cause has never been very potent in Melanesia, and is now well under control.

(To be concluded.)

ANNUAL REPORT FOR 1918 TO THE BOARD OF EDUCATION.

THE annual report for 1918 of the chief medical officer of the Board of Education deals fully with the medical aspect of the new powers and duties of education authorities under the Education Act, 1918. The former requirement of medical inspection in public elementary schools is extended to secondary and continuation schools. Local education authorities now *must* secure medical treatment for public elementary school children, and *may* extend it to pupils in other schools; the employment of any individual child may be prohibited by new by-laws upon the report of a school medical officer; physical training of children and young persons up to 18 years of age is facilitated by local education authorities being enabled to make provision for holiday camps, playing fields, and other arrangements for social and physical training in the day or evening.

Medical Inspection in Secondary Schools and Continuation Schools.

The purpose of medical inspection is somewhat different at present in secondary and elementary schools. In secondary schools education is continued to a later age, and includes the period of puberty, during which the pupils, and especially the girls, are liable to mental and physical fatigue and overstrain. Athletic exercises play a larger part in the curriculum; medical inspection is directed towards the detection of tendency to cardiac weakness or other physical defect likely to be increased by any special form of physical exercise. The Board state that a full examination should be made at the ages of 12 and 15 years, and a yearly examination after 12 years of age, the degree and extent of which would vary according to the previous record and other circumstances of the pupil. The inspections which have already been carried out show that 25 to 50 per cent. of the pupils are usually found to require treatment, mostly for dental caries, defective vision, enlarged tonsils, disorders of the heart, malnutrition, anæmia, spinal curvature, and flat-foot. Treatment is usually given by the family doctor, except in certain municipal schools, where advantage is taken of facilities provided by the authority.

A new chapter in preventive medicine is opened by the extension of the work of the School Medical Service through the all-important period of a child's life, when he is passing from the years of school age to those of choice of, and entry into, some branch of employment. Medical inspection at the continuation school is necessary to detect defects which may render particular forms of employment unsuitable for a young person. It is also required in order to ascertain new or accentuated defects arising from employment, especially for the detection of any poisoning, lung trouble, injury to vision, cardiac strain, tuberculosis, or other physical damage likely to be caused by any special form of industrial employment. If a welfare supervisor or a similar person appointed by a firm assists the medical officer in securing treatment for defects, special care must be taken to avoid any suggestion that the results of medical inspection are being used unfairly to prejudice prospects of employment. It will generally be found most convenient to extend to pupils in continuation schools the "clinic" and other facilities available for children in elementary schools. A fair number of industrial concerns have made, in connexion with their welfare schemes, certain definite provision in respect of the physical well-being of young persons and others in their employ. A whole-time medical officer is often employed; all new employees are medically inspected; dental inspection and treatment, baths, remedial exercises, and meals are provided. Where such whole-time medical officers are employed the introduction of the medical board system would be useful with the school medical officer or one of his assistants as a member of the board. In this way the school medical officer will be thoroughly familiarised with the type of defect or child unsuitable for any form of employment offered by the firm, and coöperation between the medical officer of the firm, the school medical officer, and the juvenile employment officer of the education committtee will be facilitated. The Lincs (Lindsey) Education Committee have drawn up a set of draft rules, given in the report, which should serve to ensure that no child is employed in a manner prejudicial to his health and education.

---

[2] Report of the Commission appointed to inquire into the Decrease of the Native Population (Colony of Fiji), Suva, 1896.

Physical Training.

Sir George Newman points out that physical training is not playing the part it should in the education of children and young people. Physical training cannot be properly organised without organisers; he is, fortunately, able to record that 51 authorities are now employing recognised organising superintendents, a very considerable increase having been made within the last year or two. No longer is it necessary for men to seek training abroad; one-year courses of physical training have now been arranged at the Municipal Training College for Men at Sheffield, primarily for certificated teachers who have served with the Army Physical Training Staff and have shown special ability for physical training. The Board of Education are encouraging the treatment of such deformities as spinal curvature at school clinics by remedial gymnasts. At present 68 bodies (local education authorities and voluntary associations) are conducting approximately 254 play centres; the organiser of physical training should be closely associated with these centres and be generally responsible for the games, dancing, physical training, &c., which form an important part of the training.

In the autumn of 1918 the Board appointed a small representative committee to consider recommendations invited from experienced gymnastic teachers as to alterations of the existing syllabus of physical exercises. As a result, two pamphlets have been issued, one dealing with physical exercises for infants, the other with suggestions in regard to games, and the syllabus has been slightly modified. Generally speaking, the new syllabus is less formal, "breaks" rather than rests between the exercises have been recommended and half the lesson, it is suggested, should be given up to "general activity exercises," including games.

In view of the importance of open-air education, all those interested in education will welcome the experimental arrangement of the London County Council, whereby grants are made towards school journeys. The remainder of the costs are borne by the parents and the School Journeys' Association. Liverpool and Birmingham are among the other authorities which make similar provision.

Surgical Tuberculosis.

Mr. H. J. Gauvain, in a report on a hospital school for the treatment of surgical tuberculosis, invited by the Board of Education, states that "tuberculosis officers, while recognised experts in the treatment of pulmonary tuberculosis, have often had little experience in the diagnosis and treatment of surgical tuberculosis. Facilities for their instruction in surgical tuberculosis should be available at special hospitals devoted to that condition. School medical officers would also greatly benefit by a course of special study at such special hospitals, as earlier diagnosis of surgical tuberculosis would then be often possible with its corresponding advantage to the patient." Study leave is provided by the Navy, Army, and Indian Medical Services; similar provision for members of the Public Health Service can only be a matter of time.

Coöperation Between School Attendance Officers and School Nurses.

Satisfactory arrangements are necessary to ensure full coöperation between school attendance officers and school nurses. Absence from school is largely on account of illness, real or alleged; progress is being made in the appointment of officials equipped with the medical knowledge necessary to carry out the work satisfactorily. A school attendance officer, useful as is his work on the penal side, cannot be expected to have the knowledge of medical work possessed by the school nurse, who has given at least three years of her life to hospital work. The need for school attendance officers will always exist, notably in rural areas, but in towns, when vacancies occur, the readjustment of the work and the advisability of the appointment of an attendance officer nurse should be considered. At Bradford it has been decided to appoint four women as attendance officer nurses. Their duties will be to visit and report on all cases referred to them by the ordinary officers in which ill-health is given as a reason for persistent irregular attendance; they will either take steps to secure that the necessary medical treatment is obtained by the parents or refer the matter to the prosecuting officer.

Prosecutions have for the first time been undertaken for neglect of children who had suffered from scabies. In 1918 the education committee of the Durham County Council authorised legal proceedings to be taken under Section 12 of the Children Act, 1908, against parents whose children had suffered from scabies for many months, after having been instructed in the methods of ridding their family of the disease. As a result in 7 out of the 10 cases the children were cured before the adjourned cases were re-heard, and Dr. Eustace Hill was able to report that scabies decreased in the county.

Provision of Meals.

In the section on the provision of meals is included a very practical résumé of the Memorandum of the Committee on Accessory Food Factors or Vitamines. The quantities required for one-course non-meat dinners for 100 children as provided at Hull are given. Dr. E. J. H. Fraser states that the change to vegetarian diet which was necessitated by the compulsory rationing of meat caused some trouble at first, the children appearing to dislike the food, but later they consumed it with enjoyment. Meals containing beans were not popular. In view of the advisability of a mixed meat and vegetarian diet and the indisputable fact that it is the meat element of the diet that parents fail to provide such vegetarian meals should only be provided when circumstances prevent the use of meat. For rural schools where the children come from a distance the arrangements for the supply of a mid-day meal at a West Sussex school serve as a model. The regularity of the attendance was unusual—95 per cent. for nearly three years. The school includes 60 infants, many of whom live from one and a half to three miles away.

The Blind.

A school medical policy for the blind child is outlined in the report; the especial need of nursery school provision and vocational education is clearly demonstrated; no less than 12 per cent. of the blind have not received any form of industrial training. The Departmental Committee on the Welfare of the Blind recommended the expansion of facilities for the separate elementary education of myopic and partially sighted children. The number of blind persons of all ages in England and Wales is 33,965; of these the Advisory Committee on the Welfare of the Blind were able to obtain information relating to 25,840; 20 per cent. of the blind population they ascertained suffer also from mental deficiency, including epilepsy and serious nervous debility. It is fortunate, therefore, that the Birmingham Institution for the Blind, in conjunction with the National Institute for the Blind, propose to establish an institution for some 100 blind mentally defective children at Smethwick. A small institution for 39 blind mentally defectives is already provided at Hastings; the need for a similar institute for the North of England is self-evident.

There is a secondary school for the blind—the Worcester College for the Higher Education of the (Male) Blind, whence half the pupils proceed to the universities. The list of old pupils securing successful careers includes 41 clergymen and ministers, 8 teachers of music, 7 teachers of other subjects, 1 barrister, 5 solicitors, 4 engaged in commerce, 2 masseurs, and 4 farmers. The remainder include many boys of independent means who live at home. Sir Arthur Pearson contemplates the establishment of a school for the higher education of girls at Chorley Wood.

Medical and Dental Treatment.

The provision of medical treatment for elementary school children has reached such a stage that it is reasonable to give the number of authorities who have not made such provision. Of 318 authorities 58 have not provided treatment for minor ailments, 76 have made no provision for treatment of defective vision, 83 no provision for supplying spectacles, 149 no arrangement for treating dental defects, and 189 provide no treatment for enlarged tonsils and adenoids.

The section on dental disease and treatment includes quotations from three significant reports dealing with the whole question—viz., the report of the Departmental Committee on the Dentists' Act, 1878, the proposals of the British Dental Association, and the special report of Mr. Norman Bennett, the chairman of the Representative Board of the British Dental Association, who was requested by the Board of Education to visit various school dental clinics in a consulting capacity and report as to their working and administration. The reports differ as to the advisability of meeting the shortage of qualified dentists available for the treatment of school children by the appointment of dental dressers working under the supervision of a qualified school dentist. The Departmental Committee strongly expressed their approval of a system of dental dressers in school dental work under competent supervision, but their recommendation must be read in connexion with their recommendations respecting the reorganisation of the dental profession. The National Dental Service Committee, whose suggestions were adopted by the Representative Board of the British Dental Association, considered that in suitable cases and under careful regulations senior dental students might be allowed to work in school dental clinics. Mr. Bennett holds that the value of dental dressers remains problematical; if they should come to be employed extensively they should be given a special course of training at a dental hospital. He is convinced that "if the dentist were operating on his own patients he could not effectually supervise more than two dressers using chairs one on each side of his own; if he were only supervising but not operating he could, of course, manage more; each of these dressers, however, would frequently be in need of assistance, and the dentist ought in any case to do a considerable amount of operating on the patients of his dressers." He makes the obvious point that the usefulness of dental dressers must be limited to urban districts where there are several chairs in one room, but when we consider that Cambridge, with a school population of 7500, can find work for three whole-time school dentists it is clear that, even if the services of dental dressers are limited as above, there is ample scope for their employment. Mr. Bennett considers that, although some school dentists desire autonomy, school dentistry has intimate relations with school medical treatment, of which, indeed, it forms a part. He is strongly of opinion that more effective supervision is necessary, but that the control should be central, and that there is at present little check on the general organisation of the school dentists' work. There can be no possible objection to the work of school dentistry as a whole being inspected by a dental inspector of the Board of Education; his visits would in all probability be as welcome to the school dentists as those of the medical inspector of the Board of Education are to the school doctor. In view of the developments in the direction of providing treatment for expectant and nursing mothers and tuberculous patients, almost always in association with the school dentist, and of the proposal for inspecting and treating dental disease in children under 5 years of age, it would be extremely unfortunate if the dentists' work were removed from the general direction of the school medical officer, who is usually the medical officer of health. Mr. Bennett's report is very valuable both to the 169 school medical officers who are ultimately responsible for existing school dental clinics, and to the school medical officers on whom is placed the duty of making arrangements to initiate new schemes of school dental treatment. He clearly indicates the need for dental treatment before the age of 7 years; all children should be inspected and treated as soon as possible after reaching the age of 5 years. The maximum interval before re-inspection should be one year. General or local anæsthetics should, practically always, be used for the extraction of permanent teeth; for temporary teeth they are not usually necessary unless several are to be extracted, when a general anæsthetic is very desirable; local spray or other application is very useful for the extraction of loose or insignificant temporary teeth or roots. The custom of giving monetary rewards to children who silently endure painful extraction Mr. Bennett considers to be radically wrong; the infliction of unnecessary pain is scientifically obsolete and an important deterrent of future treatment.

The work of school dentists should be extended beyond the treatment of caries, sepsis, and stomatitis to the treatment of irregularities of position. The more strictly local irregularities, sometimes associated with abnormal variation in the periods of shedding and eruption of teeth, offer no difficulties to the average school dentist; complex cases involving jaw formation would be without the scope of a school clinic, but the education authority should make arrangements for their treatment at special hospitals in the larger cities and towns. Other kinds of work which might occasionally be practised justifiably at the school dental clinic include crowns for fractured incisors and obturators for cleft palate. The dentists are pleased to carry out these additional forms of work; they help to make the appointments more attractive; and anything which enlarges the scope of the duties and relieves the monotony is of advantage to the patients as well as the dentists. The school dental clinic should be fitted with a supply of hot and cold water; pump-chairs adapted to children should be installed in all whole-time clinics; electrical engines justify their expense by increased efficiency, reduction of pain, and saving of time. Every recovery room should be provided with a sink and both hot and cold water.

In London, in addition to the routine work of dental inspection and treatment, arrangements have been made for supplying at cost price tooth-brushes, tubes of tooth-paste, and small tablets of permanganate of potassium for making an antiseptic mouth-wash. A special investigation was carried out by Mr. C. Edward Wallis in South London, where some of the parents were attracted by advertisements of dental companies trading locally. The dental work of these companies was execrable; the fees charged were often in considerable excess of those charged by the properly qualified dentists.

Coöperation and Progress.

Evidence of coöperation between the Ministry of Health and the Board of Education is afforded by the egulations on the training of health visitors and of midwives which have been issued as the result of the con-ultation between these two Departments. The report s emblematic of the times, its note is progress, it bears vidence of thought which has been slowly maturing uring the lean years of high thinking and enforced ow living. Sir George Newman has a genuine gift for ducating his readers.

THE REPORT OF THE COMMITTEE UPON ANAEROBIC BACTERIA.[1]

THIS report summarises in a very readable form our present-day knowledge of most anaerobic bacteria, of he morbid conditions they may cause, and of the urgical and serum treatment which should be practised. t is the conjoint work of a committee under the chairmanship of Dr. William Bulloch, F.R.S., assisted in ertain sections by writers with special knowledge. The volume is packed with information, and should be of great help to laboratory specialists, and of first interest to the thousands of medical officers whose unhappy duty it was to treat and care for the cases of gas gangrene and tetanus during the war.

The section devoted to the clinical features of anaerobic infections of wounds is written by Dr. John Fraser; the committee are responsible for the bacteriology and biochemistry of anaerobes, for the section dealing with the experimental study of gas gangrene, for he description of toxins and antitoxins and their therapeutic use. Major W. J. Tulloch writes a special section on recent work on tetanus, Dr. A. Fleming contributes an article on the aerobic organisms found in wounds, and Dr. E. H. Kettle writes an account of he histo-pathology of gas gangrene.

The varieties of disease which anaerobic bacilli may et up in a wound vary from comparatively localised infections—gas abscess—to spreading massive œdema and the extraordinarily fulminant cases of gas gangrene. The type of disease which occurs does not apparently depend entirely on the particular species of anaerobe ound in the wound, but is affected by circumstances not yet completely unravelled. Clinically it is found hat the nature of the wound, the general condition of the wounded man, the vascular supply, and the regions and tissues affected all have some influence upon the final form of the infection; but "the fulminating type stands out in contrast to all other varieties." Whatever he form the infection takes, surgical intervention, and usually of a drastic order, is called for; this varies naturally with the extent and nature of the lesion. The detailed consideration of this aspect of the subject is given by Dr. Fraser and must be left to the reader to appreciate.

Anaerobes Found in Soil.

Of the anaerobes found in soil it appears that half-a-dozen are pathogenic to man. Of these, three have been known for many years: *Vibrion septique*, discovered in 1877 by Pasteur, *B. tetani* described by Nicolaer in 1884, and *B. welchii* by Welch in 1892. In the years before the war *Vibrion septique* was generally called *B. œdematis maligni*, a name given to the organism by Koch subsequent to the publication of Pasteur's work. There is now practically no doubt as to the identity of the organisms studied by Pasteur and Koch, though in the first two years of the war great uncertainty existed on this point.[2] The explanation appears to be that neither Pasteur nor Koch gave a sufficiently detailed description of the cultural characteristics of the organisms they worked with, and most, if not all, of the strains maintained in laboratories before the war were impure. The most common impurity present was *B. sporogenes*. This latter anaerobe is powerfully proteolytic, liquefying coagulated serum rapidly, whereas the proteolytic properties of *Vibrion septique* can be detected only by refined biochemical methods. Thus the general description of *B. œdematis maligni* (*Vibrion septique*) found in standard text-books of bacteriology is inaccurate; it is stated to be proteolytic, as tested by ordinary laboratory methods, the error being due to *B. sporogenes*. This point has now been set right by the Anaerobe Committee. The remaining three pathogenic anaerobes, derived from soil, are *B. œdematiens*, *B. fallax*, and *B. histolyticus*. They were all discovered during the war by Weinberg and Séguin, an achievement reflecting great honour on French bacteriology.

The relative frequency of occurrence of these microbes in gangrenous wounds is given by French and English observers as follows: *B. welchii* about 70 per cent.; *Vibrion septique* about 16 per cent.; *B. œdematiens*, *B. fallax*, and *B. histolyticus* the remainder (about 14 per cent.).

Cultural Reactions of the Organisms.

The description of the cultural reactions of these organisms is given in great detail and is remarkably complete. Of the large number of species of non-pathogenic soil anaerobes *B. sporogenes* (Metchnikoff) and *B. parasporogenes* (McIntosh) are the most important. These two germs are distinguished from one another by certain small cultural differences and by agglutination tests. They occur in 25 per cent. of gangrenous wounds, and probably aid the morbid processes in some way not yet exactly understood. Owing to their strong saccharolytic and proteolytic properties they produce in sugary and albuminous media an abundance of acid and gas, of ammonia and amino-acids. The acids may aid the growth of the pathogenic anaerobes directly or by reducing the resistance of the wounded man. In a more or less similar way other merely saprophytic anaerobes (*B. tertius*, *B. cochlearius*, *B. tetanomorphus*, &c.) probably contribute to the production of the gas-gangrene syndrome.

B. sporogenes is widely distributed in nature and is very resistant to heat and antiseptics; it withstands exposure to 100° C. for 45 minutes and survives eight days in 5 per cent. phenol solution. It has already been referred to as the commonest contaminator of *Vibrion septique* and other anaerobic cultures; this is due to the great tenacity to life possessed by the spores and to a phenomenon called, in the report of the Anaerobe Committee, "microbic association." By this is meant the "power of cryptic proliferation within the characters of another species without being detectable." The committee find the capacity of mutual adjustment possessed by anaerobes, and by *B. sporogenes* in particular, to lie at the root of nearly all the more serious confusions and discrepancies in the literature of this subject.

Aerobes Found in War Wounds.

In the section devoted to the aerobes found in war wounds Dr. Fleming shows that the primary infection is fæcal in origin. Thus the *Streptococcus fæcalis* is found in 38·8 per cent. of cases on admission to the casualty clearing station, whilst hæmolytic streptococci occur in only 18 per cent. After a week's sojourn in hospital the percentage of the latter type of coccus increases to 90 per cent.—that is to say, the comparatively harmless, or merely saprophytic, organism tends to disappear, whilst the pathogenic and often dangerous *Streptococcus pyogenes* appears more frequently. The same phenomenon is to be observed with respect to other organisms. Whence the source of this secondary infection? Is it by direct spread from surrounding skin or is it a hospital infection? Levaditi and Debez have brought forward interesting observations which bear upon this question. They found that 54 per cent. of the English soldiers had streptococci habitually in the epithelial squames of the skin, whilst among Belgian soldiers in rest the percentage is as low as 12. They further state that wounds of Belgian troops were less often contaminated with streptococci than were those of English troops. We have here some evidence that direct spread from the skin plays a part, but, allowing for this, the evidence is practically conclusive that the majority of cases are infected during the dressing of wounds in hospital. It is borne out by common experience of *B. pyocyaneus* infections. If a wound in a ward is infected with this chromogenic organism the other cases in the ward soon show evidence of its presence unless the most rigid precautions be taken.

---

[1] Medical Research Committee, Special Report Series, No. 39. By Drs. W. Bulloch, S. R. Douglas, W. E. Gye, H. Henry, J. McIntosh, R. A. O'Brien, Miss M. Robertson, and C. G. L. Wolf.

[2] THE LANCET, 1918, i., 188.

Among many interesting observations recorded in this section reference may be made to the work of Canadian officers on the occurrence of true diphtheria bacilli in wounds. FitzGerald and Robertson reported that out of 67 cases arriving in Toronto between May 20th and June 7th, 1917, *B. diphtheriæ* was discovered in 40. This very high percentage was subsequently explained by the fact that one of the nurses who dressed wounds had a digital lesion infected by this organism. Apart from such an exceptional occurrence it has been found that 2 out of 306 wounds were infected with *B. diphtheriæ*.

The Influence of Aerobic Bacteria on the Growth of Pathogenic Anaerobes in Wounds.

This subject has been investigated by a number of observers, especially in France. In the course of experiments on the ætiology of tetanus, made as long ago as 1893, Vaillard and Rouget found that the spores of *B. tetani* when deprived of toxin by the application of heat were non-pathogenic for animals of a susceptible species, and that pathogenicity could be restored by protecting the spores against phagocytes. This it was found could be achieved by injecting other organisms along with spores or by protecting the latter by means of sand; also by inhibiting the migration of leucocytes to the site of inoculation by means of lactic acid. The general conclusion arrived at was that spores or bacilli unprotected by one or other of the above-mentioned devices are rapidly ingested by phagocytes and prevented from dividing and producing toxin. Similar experiments were made by Besson with *Vibrion septique* with the same results. The spread of the primary anaerobic infection in wounds is attributed by Tissier to the action of associated aerobic bacteria. He maintains that when the aerobes are harmless saprophytes (as they generally are for the first two or three days after the infliction of a wound) "the anaerobic infection is slow; it is more rapid when the associated bacteria belong to the pyogenic group; and it tends to become fulminating when the streptococcus is present." There is undoubtedly some truth in these general contentions, but in face of the fact that pathogenic anaerobes are constantly found in association with virulent streptococci in non-gangrenous wounds it cannot be held that pathogenic aerobes play a predominant part in the ætiology of gas gangrene. Further, experimental work carried out during the war has shown that the main conclusions of Vaillard and Besson and others are probably incorrect. Evidence has been brought forward showing that water-soluble constituents of cultivated soil play a part in the genesis of these grave infections. An account of these researches are found in the section on experimental gas gangrene.

Description of Toxins.

The general mode by which anaerobic bacteria effect pathological changes is by the production of toxins and by invasion of the tissues, the latter depending upon the former. A careful study of the toxins elaborated by these organisms has therefore been made, and is fully described in the report. Of many points of special interest one or two may be touched upon here, with the assumption that the full document may be referred to.

The general properties of these poisons are as follows: They are unstable to heat, being destroyed at 70° C. in 30 to 60 minutes; they depreciate considerably when filtered; and they are rapidly destroyed by acids.

The toxin of *B. welchii* is hæmolytic both in vivo and in vitro; it necroses muscle and causes the production of a serous œdema in the subcutaneous tissues; it is antiphagocytic. The killing dose of this toxin is very high compared with that of diphtheria and tetanus—namely, about 0·25 c.cm. *Vibrion septique* produces a toxin with very similar properties, except that when it is injected subcutaneously or intramuscularly very large doses are required to kill an animal; injected intravenously, however, the toxin kills an animal (rabbit or mouse) in a few minutes. The absence of a definite incubation period is very remarkable. The toxin of *B. œdematiens* is extremely potent; a killing dose of 0·0003 c.cm. is often observed.

All three of these toxins have antigenic properties and the antisera obtained are found to neutralise each of the poisonous qualities enumerated above. When a dose of culture of one of these organisms is mixed with an appropriate amount of antiserum, and the mixture is injected under the skin, the animal remains in good health. The serum neutralises the toxin in the culture and the bacilli, being non-pathogenic in themselves, are phagocyted and destroyed. An animal may also be protected against a lethal dose of culture by prophylactic injection of the serum, but when the serum is injected separately, and after the culture, the animal, as a rule, dies. This applies particularly to *Vibrion septique*; with *B. welchii* the interval between the injection of the culture and (later) of the serum may be several hours and protection is obtained. With *Vibrion septique* it is rare that an animal is saved by serum which is administered subcutaneously or intramuscularly even a few minutes after the culture. When, however, serum is administered intravenously its curative effect becomes evident; an animal which is already ill from the effects of an injection of a broth culture of either *B. welchii* or *Vibrion septique* may often be saved by the intravenous injection of large doses of potent antisera.

Conclusion.

The practical conclusion to be drawn from these experiments is that antigas gangrene serum must be given as early as possible, in as large doses as possible, intravenously and also subcutaneously in the region of the wound. Occasional cases of this horrible complication of injuries occur in civil practice, and the correct method of using serum ought to be widely known.

Antigas gangrene serum was not prepared on a large scale until the last year of the war, and consequently its therapeutic properties were never properly tested. The serum to be effective must be polyvalent. It must, at least, protect against *B. welchii*, *Vibrion septique*, and *B. œdematiens*. The first supplies sent to France were monovalent, and it was not until the last few months of the war that an active polyvalent serum could be produced in large quantities. The records of its use in war must be interpreted, therefore, in the light of these facts. So far as these records can be analysed they show, the committee consider, "that the results obtained in France have exceeded expectations."

The more technical parts of the book, such as the biochemical and histological section and the account of recent researches on tetanus, are too intricate to make any short summary of value. The bibliography is surely a record of completeness, and will alone render the volume indispensable to all investigators in the field of anaerobic bacteria.

TUBERCULOSIS.

Life Assurance and Tuberculosis.

IN a paper read before the Assurance Medical Society on Nov. 5th, and published in the January number of *Tubercle*, Dr. Otto May has reviewed the problem of life assurance as related to tuberculosis in the light of recent research. This has undoubtedly provided much useful material to guide the medical examiner for life assurance in his estimate of the expectation of life in any given case showing one or more of the stigmata of tuberculosis. But the discussion which followed the reading of Dr. May's paper, and which is to be resumed on Jan. 7th revealed certain divergences of opinion, as well as gaps in our knowledge of this particular problem We may, indeed, claim to have advanced our knowledge of tuberculosis since a distinguished physician a genera tion back confessed that of one thing only could he be sure—his prognosis would be wrong. But it would be presumptuous folly to argue that whereas we were blind, we now see. We are still groping. Let us take, for example, the relation of wealth to the mortality from tuberculosis. Tuberculosis is a disease from which, speaking broadly, the poor man dies and the rich man recovers. But there are no reliable data to express this difference with the necessary exactitude. Again, the relation of mental stability to tuberculosis is but imperfectly understood; we know that the mentally defective and the insane are peculiarly liable to contract fatal tuberculosis, and every sanatorium physician has good reason to endorse the aphorism—no fool ever recovered from tuberculosis; blind to his general interests he does not benefit by institutional regimen. But of the tuberculosis rate among the mentally ill-balanced or merely stupid, as compared with intelligent persons, we know little; we may have a shrewd suspicion that a well-balanced mind and a stable nervous system are of enormous importance, but we cannot at present express the significance of these factors in actuarial terms.

Dr. Hector Mackenzie, in his discussion of Dr. May's paper, referred to the much-quoted investigations by the late Dr. C. Theodore Williams, who found that the average duration of life after the outbreak of the disease was about eight years. This conclusion was arrived at by mixing shorter cases with longer ones—a process giving no clue to an intelligent discrimination of individual cases. Such an analysis is almost as misleading as an estimate of the mortality of the fevers of the enteric group investigated on the same lines. It is far from enough for the life assurance examiner merely to know that the average expectation of life for a consumptive is eight years; he wants to distinguish between the short and the long case. He may often not be able to do so at once. He has, however, a most useful guide in the findings of various sanatoriums, Midhurst in particular, which show that after the first three years the prognosis for the patient discharged from a sanatorium is comparatively good. These are the important investigations that enable the life assurance examiner, in the words of Dr. May, "to recommend for acceptance, with a moderate contingent debt, cases with a history of phthisis dating back five years, who appear free from all symptoms and signs of active disease." It may be noted that neither in Dr. May's paper nor in the discussion that followed was any direct reference made to Dr. J. Brownlee's investigations into the characteristics of various forms of tuberculosis as manifested at the different periods of life. If confirmation of his views is forthcoming (and it appears that Dr. Arne Fisher, in a recent analysis of the male tuberculosis mortality of Christiania in the period 1900–1910, endorses Dr. Brownlee's findings) we may have to alter some of our conceptions in relation to life assurance and other aspects of the tuberculosis problem. At present we still cannot tell why tuberculin achieves a few dramatic successes which punctuate, as it were, the long lists of its negative or even harmful results. We may guess, but we cannot yet be sure, that these apparently conflicting observations are the outcome of our inability to differentiate between various strains of the tubercle bacillus, and that if we can distinguish between the members of the tubercle family, as we already do between the members of the typhoid family, we shall have advanced a long way towards a surer prognosis and a more rational and specific treatment. Such a differentiation may tell us why one case terminates fatally in a few months, while another survives by half a century the first manifestations of the disease, and justifies the saying of an American physician that the secret of long life is to suffer from an incurable illness and to have learned how to take care of oneself.

It is impossible to follow this discussion of life assurance in relation to tuberculosis without being driven to the conclusion that, as matters now stand, the potential consumptive is most heavily handicapped just at a point where an equal start or a substantial handicap in his favour is much needed. So long as life assurance is a matter of private enterprise, it is obvious that the medical examiner must make the interests of his employers his first object. The medical profession has, however, duties to discharge also to the sick and to the community at large. And it is in the interests of neither that the potential consumptive should be penalised in such an important matter as life assurance. The doctrine of taking from him that hath not might in this case find some justification if, in stamping on the tuberculous, we were stamping out the disease. But the reverse principle is much nearer the truth and, quite apart from any element of philanthropy, the community should realise that, in shouldering the burden of the consumptive, it is taking a most important step towards protecting itself and eliminating the disease. Hitherto this burden has been shouldered half-heartedly, even grudgingly; the result of this attitude is evident in the candid confession of failure recently voiced by the medical adviser to the London Insurance Committee in his report on a system conspicuous both for lack of sanatoriums and of other "benefit."

Tuberculosis under the Insurance Acts.

Recent questions in Parliament have elicited from the Minister of Health some points in regard to the Government's plans in dealing with tuberculosis. Dr. Addison stated that he was not at all satisfied with the results obtained under the Insurance Acts, but to circumstances connected with the war it was fair to attribute the larger part of the incomplete success attending the measures inaugurated in 1911. Steps, he added, were now being taken to carry out the recommendations of Sir Montague Barlow's Committee; the system of administration was being overhauled, but it would take a generation to catch up. Dr. Addison thought the formation of a special department at the Ministry of Health for tuberculosis to be most undesirable.

The Cost of Tuberculosis Treatment.

The amount expended by public authorities in England and Wales on the treatment of tuberculosis during the financial year 1917–18 was approximately £1,550,000. This is the latest period for which complete figures are available. It is estimated that the expenditure during the present financial year will exceed £2,000,000. In neither case is the expenditure defrayed by loans included in the figures.

The numbers of persons who have received sanatorium benefit in England and Wales during the past five years are as follows: 1914, 31,793; 1915, 29,741; 1916, 29,850; 1917, 31,566; 1918, 35,430.

Open-air Orthopædic Hospitals.

The proposals of Sir Robert Jones and Dr. G. R. Girdlestone, of Oxford, for the establishment under the Ministry of Health of open-air country orthopædic hospitals for children suffering from rickets, infantile paralysis, and surgical tuberculosis on the model of the Baschurch and Stokes centres for crippled children, are under consideration at the Ministry. Dr. Addison described their scheme in Parliament recently as one (a very important one) of those special institutional services which greatly need development, and which are now under the direct consideration of the Consultative Councils.

Sanatorium Accommodation in East Sussex.

There are six approved sanatoriums in the county of East Sussex, including the county boroughs of Brighton, Eastbourne, and Hastings. These contain accommodation in all for 248 patients—146 men and 102 women and children. The 146 beds are all available for discharged soldiers. The need for further accommodation is being met by the purchase by the County Council of a site and buildings with a view to the provision of a new sanatorium of 120 beds.

THE John Rylands Library in Manchester is making progress with its scheme of restocking the lost library of the University of Louvain. The picture is still fresh in the minds of many, showing books, a large proportion of them German books, being thrown out of the windows in September, 1914, by the apostles of German culture. More than 21,000 volumes have now been received and catalogued in Manchester, and a first instalment of these is on its way to Belgium.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

A MEETING of the General Council of King Edward's Hospital Fund for London for the purpose of granting awards was held at St. James's Palace on Dec. 16th, under the presidency of the PRINCE OF WALES. The meeting was an exceptionally important one, because, as we pointed out recently in these columns, the position of hospital finance at the present time, owing to the war, is very precarious. Recognising this, the Fund has made specially increased grants.

Lord REVELSTOKE, the honorary treasurer, said that the receipts on general account to Dec. 6th, after deducting expenses, amounted to £158,338 11*s.* 9*d.* With the help of the League of Mercy the total receipts for the year would be £180,000, and this sum, together with certain undistributed balances, would enable the Executive Committee to recommend the distribution of £230,000.

Sir WILLIAM COLLINS, on behalf of the League of Mercy, said that £17,000 would be handed over to the Fund, an advance of £1,000 on last year's figures, and £3000 on the last pre-war figures.

Report of the Distribution Committee.

The report of the Distribution Committee was presented by Sir JOHN TWEEDY, chairman of the Committee. It stated that the sum of £218,000 was available for distribution amongst the London Hospitals, as against £190,000 in 1918, an increase of £28,000, and that the number of hospitals applying for grants was 107. Of the total amount distributed £174,625 had been applied in the form of grants to maintenance, an increase of £14,375 over the corresponding total in 1918. The following grants in aid of schemes of building expenditure were recommended for renewal under the two years rule: General Lying-in Hospital, £1000 in 1917 to improvements; Hospital and Home for Sick Children, Sydenham (now South-Eastern Hospital for Children), £75 in 1915 to central heating; Queen Charlotte's Lying-in-Hospital, £1000 in 1913 and £650 in 1917 to new out-patient department; Queen's Hospital for Children, £288 12*s.* 11*d.*, balance of £1000 in 1917 to improvements in the out-patient department; St. Mary's Hospital for Women and Children, Plaistow, £1500 in 1913 and £1000 in 1917 to new nurses' home and out-patient department; Victoria Hospital, £200 in 1916 to new heating apparatus.

List of Awards.

Sir FREDERICK M. FRY, the honorary secretary, then presented the list of awards as follows. (It should be noted that the reduction or absence of a grant does not necessarily imply dissatisfaction):—

Acton Hospital, £170.

Alexandra Hospital for Children, £200.

Beckenham Cottage Hospital, £60.

Belgrave Hospital for Children, £1125.

Blackheath and Charlton Hospital, £145.

Bolingbroke Hospital, £1000.

British Hospital for Mothers and Babies, Woolwich, £1730, of which £1500 towards the building of the amalgamated hospital, in accordance with the scheme submitted to the Fund.

Canning Town Women's Settlement Hospital (late Medical Mission), £700, of which £100 to reduce debt.

Central London Ophthalmic Hospital, £550

Central London Throat and Ear Hospital, £225

Charing Cross Hospital, £4600, of which £500 to improvements.

Chelsea Hospital for Women, £2150, of which £1500 to reduce debt.

Cheyne Hospital for Sick and Incurable Children, £400, of which £50 to reduce general fund overdraft.

City of London Hospital for Diseases of the Chest (Victoria Park), £4500, of which £500 to proposed sanitary improvements, in accordance with the scheme submitted to the Fund.

City of London Maternity Hospital, £1550, of which £500 to reduce general fund debt.

Clapham Maternity Hospital, £1025, of which £100 to scheme.

Dreadnought Hospital, £3250.

East End Mothers' Lying-in Home, £850.

East Ham Hospital, £215.

East London Hospital for Children, £2750.

Elizabeth Garrett Anderson Hospital, £1400, of which £250 to the scheme for the adaptation of the adjoining premises for out-patients and nurses.

Eltham and Mottingham Cottage Hospital, £120.

Finchley Cottage Hospital, £110.

Florence Nightingale Hospital for Gentlewomen, £350, of which £100 to reduce debt.

French Hospital, £200.

General Lying-in Hospital, £1600, of which £100 to reduce debt and £1000 to scheme of rebuilding to be submitted to the Fund.

Great Northern Central Hospital, £6100, of which £1500 to new nurses' home in accordance with scheme to be submitted to the Fund.

Grosvenor Hospital for Women, £575.

Guy's Hospital, £11,000, of which £2000 to improvements in nursing accommodation, in accordance with the scheme submitted to the Fund.

Hampstead General and North-West London Hospital, £3200, of which £1500 to reduce debt.

Hendon Cottage Hospital, £30.

Hornsey Cottage Hospital, £25.

Hospital and Home for Incurable Children, Hampstead, £100, of which £50 towards provision of operating theatre, in consideration of the fact that curable cases are admitted.

Hospital for Consumpton, Brompton (including Sanatorium at Frimley), £7150.

Hospital for Diseases of the Throat, £625, of which £500 towards loss incurred by postponement of building scheme through the war. The Committee trust that the scheme will be pushed forward as rapidly as possible.

Hospital for Epilepsy and Paralysis, £2225, of which £500 to reduce debt.

Hospital for Sick Children, £4600.

Hospital for Women (Soho-square), £1750, of which £250 to reduce debt.

Hospital of St. John and St. Elizabeth, £675.

Infants Hospital, £900, of which £250 to reduce debt.

Italian Hospital, £400.

Kensington and Fulham General Hospital, £50.

Kensington Dispensary and Children's Hospital, £55.

King Edward's Memorial Hospital (Ealing), £750.

King's College Hospital, £8400, of which £5000 to reduction of debt on removal to South London, making £77,100 in all contributed by the Fund to this purpose.

Leyton, Walthamstow, and Wanstead Children's and General Hospital, £750.

London Fever Hospital, £230.

London Homœopathic Hospital, £1950, of which £250 to reduce general fund debt.

London Hospital, £13,000, of which £1000 to deficit on new nurses' home, in accordance with the scheme submitted to the Fund.

London Lock Hospital, £4150, of which £1050 to maintenance of Harrow-road Hospital, £100 to maintenance of Dean-street Hospital, and £3000 to reconstruction, in accordance with the scheme submitted to the Fund, making £4500 granted to the scheme to date. No further grant will be made to the reconstruction until the Fund is satisfied that the appeal to the public is being actively pressed.

London Temperance Hospital, £2300

Maternity Charity and District Nurses' Home, Plaistow, £350.

Memorial Hospital, Mildmay Park, £550, of which £150 towards installation of electric light.

Metropolitan Hospital, £4500, of which £1000 to reduce debt.

Middlesex Hospital, £8400, of which £500 to reduce debt, and £900 to new nurses' accommodation in accordance with the scheme submitted to the Fund.

Middlesex Hospital Cancer Charity, £500, of which £100 to new nurses' accommodation.

Mildmay Mission Hospital, £675.

Miller General Hospital for South-East London, £4500, of which £2500 is a first grant to the extension of the hospital, in accordance with scheme to be submitted to the Fund.

Mothers' Hospital of the Salvation Army, £1000, of which £500 to new nurses' accommodation, in accordance with scheme to be submitted to the Fund.

National Hospital for Diseases of the Heart, £800, of which £400 to extension of out-patient department, in accordance with scheme to be submitted to the Fund.

National Hospital for the Paralysed and Epileptic, £4000.

Nelson Hospital (late South Wimbledon, &c.), £550.

Norwood Cottage Hospital, £450.

Paddington Green Children's Hospital, £900.

Passmore Edwards Hospital for Willesden, £250.

Passmore Edwards Hospital for Wood Green, &c., £115.

Poplar Hospital for Accidents, £250.

Prince of Wales's General Hospital, £6000, of which £3000 to reduce general fund debt.

Queen Charlotte's Lying-in Hospital, £2000, of which £500 to reduce debt, and £700 to deferred scheme of improvements.

Queen Mary's Hospital for the East End, incorporating West Ham and Eastern General Hospital, £5250, of which £1000 to nurses' home, in accordance with scheme to be submitted to the Fund.

Queen's Hospital for Children, £4500, of which £625 to extinguish debt on old building scheme, and £1000 to scheme for new out-patient department to be submitted to the Fund.

Royal Dental Hospital of London, £500.

Royal Eye Hospital, £700.

Royal Free Hospital, £5000, of which £1500 to new nurses' accommodation, in accordance with the scheme submitted to the Fund.

Royal Hospital for Diseases of the Chest (City-road), £1450.

Royal Hospital, Richmond, £450.

Royal London Ophthalmic Hospital, £2800, of which £500 to new heating apparatus.

Royal National Orthopædic Hospital, £1250.

Royal Waterloo Hospital for Children and Women, £4250, of which £2000 to new nurses' accommodation, isolation wards, and extension of out-patient department, in accordance with the scheme submitted to the Fund.

Royal Westminster Ophthalmic Hospital, £200.

St. Andrew's Hospital (Dollis Hill), £310, of which £250 to reduce building debt.

St. Columba's Hospital, £600, of which £250 to provision of balconies.

St. George's Hospital, £5000.

St. John's Hospital, Lewisham, £675.

St. Luke's Hospital for Advanced Cases, £250.

St. Mark's Hospital, £550, of which £100 to improvement in nursing accommodation.

St. Mary's Hospital, £4500.

St. Mary's Hospital for Wome and Children, Plaistow, £3150 of which £2000 to the rebuilding of the nurses' and servants quarters and out-patient department, (in accordance wit scheme to be submitted to th Fund.

St. Monica's Home Hospita £270, of which £100 to sanitar improvements.

St. Peter's Hospital for Stone £325, of which £200 to new lift.

St. Saviour's Hospital for Ladie of Limited Means (Osnaburgh street), £230.

St. Thomas's Hospital, £750 of which £2500 to improve ments, in accordance wit scheme to be submitted to th Fund.

Samaritan Free Hospital for Women, £1425.
Santa Claus Home, £60.
South-Eastern Hospital for Children (Sydenham), £660, of which £200 to central heating and laundry improvements.
South London Hospital for Women, £750.
Stoke Newington Home Hospital for Women, £120.
University College Hospital, £6800, of which £500 to improvements.
Victoria Hospital for Children, £1,700, of which £250 to central heating.
West End Hospital for Nervous Diseases, £2750, of which £2000 to removal to Regent's Park, in accordance with the scheme submitted to the Fund.
Western Ophthalmic Hospital, £175.
West London Hospital, £6150, of which £1500 to improvements, in accordance with scheme to be submitted to the Fund.
Westminster Hospital, £4800, of which £300 annual grant to acquisition of new site as agreed.
Wimbledon Hospital, £120.
Woolwich and Plumstead Cottage Hospital, £25; special grant to the Woolwich and District War Memorial Hospital Building Fund, £5000.

Report of the Convalescent Homes Committee.

Sir **WILLIAM H. BENNETT**, chairman of the Convalescent Homes Committee, presented a report which stated that the sum available for distribution amongst convalescent homes and consumption sanatoriums is £12,000, as against £10,000 in 1918. The number of applications eligible for consideration amounted to 49 from convalescent homes and 9 from consumption sanatoriums, as against 45 and 9 respectively last year. The number of beds reserved by the Fund for the use of patients in London hospitals amounts to 66 at six sanatoriums. In view of the universal demand for facilities for dealing with tuberculosis the small number of men's beds which the general hospitals appear to be able to use in this way is a matter which may require further consideration next year. On the other hand, the committee have been unable to secure enough women's beds to satisfy the demand.

List of Awards.

Mr. **J. G. GRIFFITHS**, honorary secretary, presented the list of awards recommended by the Convalescent Homes Committee.

A.—*Consumption Sanatoriums.*

Children's Sanatorium, Holt, Norfolk, £880, of which £780 in consideration of the reservation of ten children's beds during 1920 for the use of certain London hospitals.
Daneswood Sanatorium (Jewish), Woburn Sands, £460, in consideration of the reservation of four beds during 1920 for the use of certain London hospitals.
Devon and Cornwall Sanatorium, Didworthy, South Brent, £1250, of which £1150 in consideration of the reservation of ten beds during 1920 for the use of certain London hospitals.
Eversfield Chest Hospital, St. Leonards, £50.
Fairlight Sanatorium, Hastings, £100.
Kelling Sanatorium, Holt, Norfolk, £740, of which £690 in consideration of the reservation of six beds during 1920 for the use of certain London hospitals.
Mount Vernon Hospital, Northwood, £150.
National Association for the Establishment and Maintenance of Sanatoria for Workers, Benenden, Kent, £3610, of which £750 in reduction of mortgage debt and £2760 in consideration of the reservation of 24 beds during 1920 for the use of certain London hospitals.
Northamptonshire Sanatorium, Creaton, Northants, £1530, of which £1380 in consideration of the reservation of 12 beds during 1920 for the use of certain London hospitals.

B.—*Convalescent Homes.*

Beau Site Convalescent Home, Hastings, £75.
Brentwood Convalescent Home for London Children, Brentwood, £50.
Brooklands Home (Invalid Children's Aid Association), Worthing, £50.
Bushey and Bushey Heath Children's Convalescent Home, Bushey, £50.
Chelsea Hospital for Women, St. Leonards, £75, with a view to encouraging the admission without payment of patients direct from the hospital.
Children's Convalescent Home, Beaconsfield, £25.
Children's Cottage Hospital, Cold Ash, Newbury, £25, in consideration of convalescent cases.
Children's Home Hospital, Barnet, £25, in consideration of convalescent cases.
Convalescent Home for Poor Children, St. Leonards, £150.
Convalescent Police Seaside Home, Hove, £75.
E. G. Anderson Hospital (Home of Recovery), Barnet, £200.
East London Hospital for Children, Bognor, £150, of which £100 to reinstatement after use by military for non-hospital purposes.
Florence Emma Home (Invalid Children's Aid Association), Dover, £50.
Friendly Societies' Convalescent Homes, Dover and Herne Bay, £75.
Great Northern Central Hospital, Clacton, £100.
Great Northern Central Hospital, East Finchley, £100.
Highgate Convalescent Home for Children, Highgate, £50.
Home for Convalescent Children, Southsea, £50.
Jewish Convalescent Home (Children), Brighton, £75.
King's College Hospital, Hemel Hempstead, £150, the grant is made on condition that patients are admitted free direct from the hospital.
Metropolitan Convalescent Institution, Bexhill, £75.
Metropolitan Convalescent Institution (Children), Broadstairs, £75.
Metropolitan Convalescent Institution, Walton-on-Thames, £150.
Middlesex Hospital, Clacton-on-Sea, £50.
Miller Hospital Convalescent Home, Bexhill, £100.
National Hospital for the Paralysed and Epileptic, East Finchley, £150, with a view to facilitating the admission of patients without payment.
Paddington Green Children's Hospital, Slough, £125.
Poplar Hospital, Walton-on-Naze, £50.
Queen Charlotte's Lying-in Hospital, Kilburn, £75.
Queen's Hospital for Children, Bexhill, £100.
Royal Waterloo Hospital for Children and Women, Whippingham, £75.
St. Andrew's Convalescent Home, Folkestone, £100.
St. Andrew's Convalescent Hospital, Clewer, £25.
St. Luke's Home (Children), Woodley, Reading, £25, in consideration of convalescent cases.
St. Mary's Convalescent Home, Birchington, £50.
St. Mary's Home for Children, Broadstairs, £75, in consideration of convalescent cases.
St. Michael's, Westgate, £25.
Samaritan Free Hospital, Amersham, £55.
Sunshine Home, Hurstpierpoint, £25.
Surgical Home for Boys, Banstead, £25, in consideration of convalescent cases.
Tilford Convalescent Home for Children, Farnham, £50.
Victoria Home for Invalid Children, Margate, £25, in consideration of convalescent cases.
Victoria Hospital for Children, Broadstairs, £125.

The Report Adopted.

The **PRINCE OF WALES**, in moving the adoption of the reports and awards, read a letter from the King, in which his Majesty expressed his cordial approval of the grants this year being specially increased, and referred to the gift of £250,000 from the Red Cross Society and the Order of St. John, remarking that the fact that the Distribution Committee had been asked to undertake its apportionment was a testimony to public confidence in the Fund. The **LORD MAYOR** having seconded the motion it was adopted unanimously.

In referring to the arrangements of the Fund for next year his Royal Highness said that two distributions would be made, the ordinary distribution in the autumn and at another period of the year the distribution of the £250,000 from the Red Cross Society and the Order of St. John.

On the motion of Viscount **SANDHURST** a vote of thanks was accorded to the Prince of Wales, and the proceedings terminated.

ROYAL COMMISSION ON INCOME-TAX:

THE MEDICAL PROFESSION'S CASE.

THE fifth instalment of the evidence given before the Commission has now been published, and in it is found the report of the evidence of Dr. Haslip on behalf of the British Medical Association. Dr. Haslip made an excellent witness, stating things reasonably and without prolixity, and also without holding himself out as even a quasi-expert on Income-tax laws and regulations. The fact is that, when all is said and done, there are not many matters of importance which affect the medical profession, and it only, in the income-tax sphere. But there are such matters, and both for that reason, and generally, it was most fitting that there should be a representative medical practitioner in the witness chair.

Simplification of Forms and Instructions.

The first point which Dr. Haslip put forward was that the forms and instructions should be simplified, so that the ordinary practitioner may be able to deal with them with his own hand without employing an accountant or other expert. Indeed, the point was pressed further than externals, and was applied to the actual bases of taxation of different kinds of income. Dr. Haslip mentioned a number of these and, of course, it is the fact that the "statutory" or taxable income is, or may be, arrived at by summing up a number of items which, in turn, have all been ascertained on totally different footings. Thus it may be the summation of the following: (1) Ordinary professional practice, on the average of the three preceding years; (2) appointments, on the emoluments of the year of assessment, at least as regards the fixed portion; (3) fluctuating or casual profits of appointments, either on a three years' average or on last year's figures; (4) income from or value of houses, &c., not at the actual rents, but at what is called the net Sch. A assessment; (5) land in occupation, sometimes at the annual rent or value, and sometimes at double that figure, according to circumstances; (6) income from general investment at the expected income of the year of assessment; (7) war loans received without deduction at the source, and bank interest received, on the amount of the preceding year; (8) income from colonial, Indian, and foreign "securities" (bonds, mortgages, &c.) at the amount of the year of assessment; (9) from colonial, Indian, and foreign "possessions" (stocks, shares, rents) on the average of the three preceding years; but (10) if the "possessions" are of certain classes, such as shares in partnerships not controlled from this country, or interests in trust funds, then the income is to be returned on the average of the amount *brought home to this country* during the preceding three years. Of course it may be said—and it is true—that it is not often that one household has all these sources of income or anything like it. To which it may perhaps be added that if the doctor and his wife are so fortunate as to be entitled to so many sources of revenue they need not, and should not, grudge a few guineas yearly to a skilled adviser to conduct them through the maze. There is, we fear, no use attempting to deny that income-tax and super-tax are technical spheres. A physician or surgeon will no doubt hold that, even if that be so, they are on a much lower plane of professional activity than his own operations. So, perhaps, they are, but the technical difficulty remains. Our sympathies are with Dr. Haslip's aspirations, but our judgment is with Dr. Stamp, one of the most skilled, experienced, and broad-minded of official (or rather, now, ex-official) experts, when he said in evidence that to him it was pathetic to hear the cravings for simplicity when the field of operations embraces all the varieties and complications of modern social, financial, and industrial developments. The saying goes that he is a poor architect who cannot save his own fees. Every medical man knows the evil consequences which sometimes ensue on people's off-putting tendencies in calling in medical advice; he can lay the lesson to heart in the taxation sphere.

Suggested Abandonment of the Average Rule.

As regards the ordinary professional income, Dr. Haslip, speaking in a representative capacity, supported the abandonment of the average rule altogether, and taking the figures of the previous year instead. In this respect the medical profession is in accord with the great majority of witnesses, though there are dissents. The examination which followed on Dr. Haslip's statement in chief disclosed not a little misunderstanding. It was suggested that it may often be very difficult to know the amount of last year's income, for there is the disturbing element of fees earned but not yet got in. As to that Dr. Haslip gives interesting evidence: "I can speak very strongly from my own experience. What I do not receive within the first month, or two months, I would sell at a very large discount; I would take a very small amount for it." No doubt the time-limit here mentioned is intended to run from the date of sending in the note of professional services and not from the date of the attendances. It reminds one of the country monumental sculptor's remark that if he did not get his money for a tombstone within the first year after the death he had the utmost difficulty in ever seeing it at all. But, as matter of fact, this point about postponed recoveries and bad debts has not so serious a bearing, for in the case of the medical and other professions where the element of stock-in-trade does not operate, the Department freely, and as a matter of course, allows the taxpayer to elect between the two methods of making up his accounts. The one is the earnings method and the other is the cash method. The former attempts to include everything on both sides, earned and incurred, though not received or paid. The latter confines itself to cash receipts and payments only, but, of course, at the end there has to be a clearing up, and that may cause annoyance once in a way. In the course of Dr. Haslip's evidence it emerged "that in certain districts the average of money received has been accepted from doctors by surveyors of taxes. This may seem surprising, but, unless our information is wrong, it is not the exception but the rule. Of course, "average of money received" is not very accurate. What is really meant is simply that, to arrive at the three years' average, the accounts of the three preceding years are made up on a cash basis on both sides, incomings and outgoings. Needless to say, whatever method is adopted must be adhered to. Good reasons for taking the cash basis are: (1) in the opening years the fees earned might be fairly good yet after deducting outgoings, the "balance" of actual cash got in might make it rather a tight fit to maintain the establishment and pay out hard cash for tax on profits not realised; (2) ease of accounting; (3) safety; for thus there is never paid tax on an item only to find later that the item is bad.

The Allowance for Depreciation of "Plant and Machinery."

The medical profession's most distinctive income-tax claim is for an allowance for depreciation on "plant and machinery," meaning, in their case, as put forward by the British Medical Association, chiefly motor-cars and all the elaborate apparatus and machinery which are now required in doctors' laboratories and surgeries. It makes for clearness if we call this wear and tear, for depreciation is really a different matter. The present rule is that wear and tear allowances are given in trade cases only and not to any profession. What a doctor is entitled to in those respects are (1) running expenses, (2) repairs, (3) renewals. Take a car: The first cost is not allowed; neither is it to a trader. If the ca is used for, say, six years, and the doctor then dies or retires, the car may sell (though no doubt present times are exceptional) for a trifle; no tax relief can be got for this loss. If, on the othe hand, the doctor sells the car for £200 and buys anothe similar car for £800, the £600 difference is allowed as a professional expense, and it matters not, though the first car cost only £400 or £500, because cars were the cheaper. But if, owing to extended practice, the docto buys a second car, no allowance; or if he sells No. and buys a more powerful car at a correspondingl increased price, the part of the price corresponding t the extra power is additional capital, and to tha extent there is no allowance; otherwise there i an allowance as in the £600 car above stated. Th profession's claim is that there ought to be wear and tear allowance the same as to a trade This looks likely to be granted. Two arguments strongl support it. The first is the analogy of a druggist motor delivery-van. The second is the fact that, if th doctor chooses to hire his car, the whole hire is passe as a professional expense, although it includes a allowance to the owner to compensate him for wea and tear; as, indeed, for that matter, so does eve taxi or bus fare.

Suggestions Regarding Houses.

Various different suggestions are made regardi houses.

(1) That depreciation of leases should be allowed as set-off. A doctor pays, say, £8000 for the remainder the lease of a house in Harley-street, and the life of t lease is running out every year, yet there is no allo ance for that wasting nature of the asset. We have expectation that this will be altered; neither has Haslip, for he said "That is a point brought forward do not wish to press it." There are various answe The question has wide ramifications of application beyond the one profession. It is reasonable to assu that the tax element was allowed for in the pri Thus a change might result in double allowances the same thing.

(2) That there should be a fuller allowance for t portion of the house devoted to professional purpos But the allowance at present may be up to two-thi and we believe the maximum is usually passed.

(3) There is a suggestion that doctors are unde professional compulsitor to be "over-housed." T meaning is that a man finds it necessary to reside fashionable locality, and, even assuming that he uses

strictly domestic purposes a full one-third of the house space, still that accommodation is of a kind, and represents an expense, which are necessitated solely by professional considerations, and therefore there ought to be a special allowance. The same argument would apply in far reaching directions; based on truth, it none the less will probably be judged as too remote.

Separate Assessment of Partners.

Dr. Haslip then moved on to an entirely different matter—namely, that in partnership cases each partner should be separately assessed. That used to be done, but it was stopped a good many years ago. Now the firm is assessed, though the total tax is almost always arrived at after giving effect to each partner's separate tax position. That involves consideration of his (and his wife's) private income, personal abatements, family allowances, life insurance, and different rates of tax. The result is to tell each partner, more or less nearly, what is the total household income of each of the other partners, matters with which, it is obvious, he has nothing to do. This sacrifices privacy, which is the keynote of the income-tax system. Not only so, but it makes it by no means an easy matter to apportion the tax burden properly between the partners, and to press a matter of this kind is rather delicate. We have no doubt whatever that very often the tax is paid out of the firm's funds and borne by the partners in quite wrong shares under the present rule of joint charge.

The Tax Allowance for Children.

Dr. Haslip closed with an adoption of the proposals of the Board of Education with reference to the extent of the tax allowances for children. It is enough to say that these are on a very advanced scale as compared with the present figure (present maximum for any one child £40), though we do not say that the proposals exceed the actual cost of maintenance and education in the professional classes. To allow differentiation in the tax relief "values" of wives and children, according to the financial position of the household, would be a novelty in this country, and there is on the Royal Commission itself evidence of labour opposition to the idea.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Medical Guild: Discussion on State Medical Service.

AT the annual meeting of the Medical Guild held in Edinburgh a discussion took place on the question of State Medical Service. In opening the discussion the chairman, Dr. John Playfair (Edinburgh), said that whether they liked it or not they would, there was ittle doubt, in the near future be faced with a State Medical Service. The Guild was quite ready to accept uch a service if it were to be limited to the necesitous classes only, and, indeed, they would favour uch a proposal. They feared, however, that the service proposed by the Government might be of much wider scope, and might ultimately embrace the whole ommunity, including hospitals and all other institutions connected with the health of the community. This would tend to reduce all professional activities to dead level, and would entirely abolish friendly feeling and sympathy between doctor and patient, and lead to inefficient medical attendance. It would mphasise and increase all the weaknesses and faults f the National Insurance Act.

Professor W. Russell (Edinburgh) said at present it was proposed to bring all persons with salaries up to £250 a ear into the State Insurance Service. The heads of departments were striving for more power and authority, nd to be the autocrats over a servile profession. Except the cases of the necessitous, or of a particular disease, he State had no right to interfere with the relations between man and man. The new proposal had grown ut of the Insurance Act, which was regarded, especially Scotland, as a failure. The Act was a political bribe the manual labour section of the community, and had resulted in breaking in two the medical profession. The question was one not only for the profession, but also for the general community. The Guild stood for freedom of relations between the public and the medical profession; nobody should be forced into the acceptance of such a service, but it should be open to those who wished to use it.

Dr. E. Duncan (Glasgow) said he had grave suspicions of the intention of the Government in the immediate future, and that great dangers were ahead. During the last 50 years there had been various forms of government, and we had now arrived at what was supposed to be pure democracy. Such periods invariably ended in tyranny, and now a tyranny was established in which heads of departments were doing as they liked independent of the Government and of public opinion. At present these heads were chosen from political superiors, and it did not matter whether they were competent or not. It was time the medical profession insisted on having its rights conserved, and resisted a service which would divorce the practitioner from his patient. The present system of medical practice was much more to the advantage of the public than any described by advocates of a State service.

Other speakers emphasised the importance of organisation of the profession, and the education of students and of the general public in the question.

Dr. F. Porter (Edinburgh) said he understood that the sweeping aside of the National Insurance Act was under consideration, and on his proposal a motion was carried that they should urge for the abolition of the Medical Benefit Section of the Act, but retention of the Sick Benefit Section, and doubling of the amounts paid under it.

University of Edinburgh: The New Professorship of Psychiatry.

The foundation of the new chair of psychiatry having been approved by Order of his Majesty in Council, the University Court appointed Dr. George Matthew Robertson to be the first professor of psychiatry in the University of Edinburgh. The teaching of mental diseases in the Edinburgh school was first commenced by Sir Thomas Clouston. His class, although not compulsory, was very largely attended, and some time later he was appointed lecturer on mental diseases by the University, which subject then became part of the recognised curriculum. Dr. Robertson succeeded Sir Thomas Clouston as University lecturer. The new professor graduated M.B., C.M. at Edinburgh in 1885, and later held the appointments of medical superintendent of Perth District Asylum, Murthly, and Stirling District Asylum, Larbert. More recently he was physician-superintendent of the Royal Edinburgh Asylum, Morningside, and previous to his appointment as University lecturer was lecturer on mental diseases in the school of medicine of the Royal Colleges, and in the Medical School for Women. Dr. Robertson is a Fellow of the Royal College of Physicians of Edinburgh, and delivered the Morison lectures in 1911 and 1913.

University of Glasgow: New Lectureship.

At the meeting of Glasgow University Court held on Dec. 11th it was intimated that Dr. James S. Nicoll had forwarded a gift of £5000 to the University on behalf of two donors who wished to remain anonymous. The gift was for the purpose of establishing a lectureship in electrical diagnosis and therapeutics in the University in connexion with the Western Infirmary.

Glasgow Memorial to Sir William Ramsay.

On Dec. 10th in Glasgow University there was unveiled a bronze plaque, with portrait and inscription, to the memory of Sir William Ramsay. Professor J. Henderson in offering, and Sir Donald MacAlister in accepting, the memorial paid tribute to the work and attainments of Sir William Ramsay, one of the most brilliant students of Glasgow University. The medallion is the joint work of Sir J. Burnet and Mr. G. H. Paulin. Lady Ramsay was amongst those present at the unveiling ceremony.

Dec. 29th, 1919.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Treatment of Discharged Disabled Sailors and Soldiers.

SOME 15 months ago the Irish Insurance Commission, acting as agent for the Ministry of Pensions, made arrangements with the general practitioners of Ireland for the treatment of discharged disabled sailors and soldiers. The basis of remuneration was a capitation rate of 12*s*. 6*d*. for each disabled man. As neither the Ministry of Pensions nor any other authority had available any accurate record of the number of disabled men in Ireland, the capitation rate may always have been less than it should have been. In many districts it is probable that only the disabled men actually in need of medical treatment were recorded. The capitation rate was, as applying to a class of disabled men among whom the incidence of sickness was likely to be high, something more than the rate for medical benefits as yet paid to panel doctors in Great Britain. The latter rate is now being substantially raised, and the profession in Ireland is naturally discontented that so far there has been no movement to increase their remuneration.

The Royal College of Surgeons in Ireland.

At a recent meeting of the Council of the Royal College of Surgeons, Major-General R. H. S. Sawyer was coöpted a member of Council in room of the late Mr. R. D. Purefoy. General Sawyer retired from the Army Medical Service at the end of 1917, after a distinguished career. The last appointment he held was that of D.D.M.S. at Boulogne. He has since resided in Dublin. Interest is already being taken in the election of a vice-president of the College, which is to be held next June. Two candidates are in the field—Mr. R. C. B. Maunsell and Sir W. I. de C. Wheeler. Both are surgeons to Mercer's Hospital, Dublin.

The late Surgeon-General James Gaussen MacNeece.

The recent sudden death of James Gaussen MacNeece, C.B., retired Surgeon-General of the Army Medical Service, removes an Irishman of note. Born in 1856, he was the eldest son of the late Rev. James MacNeece, M.A., Rector of Clonfeacle, Moy, co. Tyrone. Educated at the Royal School, Dungannon, he gained his medical knowledge in Dublin, where he became L.R.C.P. & S.I. in 1877. In 1878 he entered the Royal Army Medical Service, and saw active service in various expeditions. He served in the South African War, was mentioned in despatches, and gained the C.B. At the beginning of the late war he was appointed Deputy Director of Medical Services, Control Board, and was transferred afterwards to India as Director of Medical Services in that country. He was subsequently invalided home, but never completely regained health or strength from his illness.

Dec. 29th, 1919.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Canadian Red Cross in France.

BEFORE finally leaving France for Canada the Canadian Red Cross Society held a farewell banquet at which the extent of its generosity to France was for the first time fully disclosed. Canada has given two million francs to the French Red Cross and similar charities, over and above the 300,000 francs sent to the President of the Republic in aid of refugees, and numerous presents in kind. The two hospitals near Paris financed by Canada, one at Joinville-le-pont and the other in the hippodrome at St. Cloud, were among the best equipped in the district, and the eight Canadian motor ambulances were at the disposal not only of the wounded but also of women, children, and old people in the invaded areas. During the war Canada has given France upwards of 30 million francs.

The Prevention of Desertion.

Dr. Box, of Tours, has recently given an account of the work done in the creche at Tours, where many infants abandoned by their mothers are housed. Late in 1916 the Prefect of the Department decided that all women delivered in the maternity hospital should remain in the creche wards for three months at least, with free board and lodging, under the sole condition that they nurse their babies. Moreover, they receive a grant of 1.50 fr. a day for so doing. The local authority pays the hospital charges, amounting to some 2 fr. a day. During the period from Jan. 1st, 1917, to Sept. 1st, 1918, 271 women (32 married, 239 unmarried) passed through the lying-in hospital. Of the 271 babies only 4 died; 51 were abandoned to the care of others by their mothers; but in no case was any child sent away from its mother if it had been with her in the home fo more than 10 days. If this method were generally adopted in maternity homes infantile mortality would be materially reduced.

Specific Treatment of Vincent's Angina.

Dr. Capitan, employed in a military hospital, has had many cases of angina under his care. All were examined bacteriologically, and he separated those cases showing both spirilla and fusiform bacilli, the so-called Vincent's angina, and subjected them to a specific treatment From August 2nd, 1914, to June 1st, 1919, 212 such case occurred. The treatment consisted in the hypodermi injection of a solution of colloidal arsenic prepared b the director of the hospital laboratory. A single injection of 6 c.cm. into the buttock was sufficient to mee the condition, without any local treatment other tha boric or peroxide gargles. In 48 hours the ulcers ar free from organisms, and a few days after they ar completely healed. This procedure gives better result than local treatment with arsenobenzol.

Open-air Schools.

In 1918, during the bombardment of Paris, scho children were evacuated and sent to schools in th country. Near Chartres an open-air school was improvised with excellent results. After four months th average weight of the children had increased by 3 kilo and the chest measurement of about 20 of them wa larger by 8 to 10 cm. MM. Armand Delille and Ph. Wapl have just issued a pamphlet advocating the univers adoption of these schools as prophylaxis against tuberculosis. M. Delille was strengthened in his views by h experience during the war in the examination at t frontier of women and children who had lived in t invaded territory and were being repatriated fr Germany through Switzerland. Impressed by t results obtained by M. Rollier at Leysin with s cures, he decided to treat on similar lines evacuat women and children who showed definite signs of tuberculosis. He suggests in his pamphlet that the healt children of tuberculous parents, in addition to actua tuberculous but non-infectious children, should be s into the country to live in healthy peasant families. in spite of the change the lesions do not improve children should then be sent to a sanatorium sch under medical superintendence.

Dec. 26th, 1919.

The Services.

TEMPORARY COMMISSIONS IN THE INDIAN MEDICAL SERVICE.

THE Secretary of State for India announces that f qualified European medical practitioners are required temporary service with Indian troops on special rates of Applicants must be British subjects of European des and should not be more than 35 years of age. If accepte appointment they will be required to enter into a contrac serve for two years. The rates of pay will be Rs.700 per men for a lieutenant, Rs.750 per mensem for a captain. Thre more years' service as a medical officer in the Home, Colo or Indian Forces is necessary to qualify a candidate for higher rate. Officers will be provided with free pass both ways. Wives and families will be sent out at Gov ment expense in the autumn of 1920, provided that ship is available. An outfit allowance of £50 will be gra except in the case of officers who have served under the War Office or the Government of India, to whom £20 only will be issued. Further particulars and forms of application may be obtained from the Secretary, Military Department, Room 157, India Office, Whitehall, S.W. 1. Envelopes should be clearly marked in the top left-hand corner "Temporary I.M.S."

ROYAL ARMY MEDICAL CORPS.

Lieut.-Col. S. G. Butler, D.S.O., relinquishes the acting rank of Colonel on ceasing to be specially employed.

Major F. Casement, D.S.O., relinquishes the acting rank of Lieutenant-Colonel on ceasing to command a Medical Unit.

Major M. F. Grant relinquishes the acting rank of Lieutenant-Colonel.

Temp. Capt. R. McRae relinquishes the acting rank of Major.

Capt. J. C. Denvir, from T.F., to be Captain.

Capt. A. Watson, D.S.O., is seconded for service with the Egyptian Army.

Capt. E. C. Linton, from Spec. Res., to be Captain.

D. C. Smelzer to be temporary Captain.

Officers relinquishing their commissions: Temp. Major E.P.G. Causton (and retains the rank of Major). Temp. Capts. granted the rank of Major: J. S. Lloyd, V. H. Mason, M.C., G. B. Warburton. Temporary Captains retaining the rank of Captain: F. J. McCarthy, T. Readman, S. P. Pollard, L. G. Reynolds, S. Potter, W. E. Cooke, D. B. Spence, H. V. Swindale, R. L. Jones, A. G. Morris, A. F. Fraser, W. J. D. Smyth, C. C. Twort, A. R. Gunn, W. G. Gordon, J. Hewat, C. H. Philips, H. W. Garden, T. G. Evans, T. T. B. Watson, V. R. Hirsch, G. W. Beresford, J. W. Potter, V. C. W. Vickers, G. H. Sinclair, A. Murdoch, A. E. Ainscow, R. S. Morshead, M.C., W. W. Stacey, J. Dickson, M.C., T. L. Jones, R. Adam, R. K. Robertson, H. L. Attwater, J. M. Sheridan, W. Niccol, E. H. Good, V. C. James, L. G. Jacob, F. G. Beatty, V. Wallace, C. St. A. Vivian, S. G. Gordon, A. Bremner, E. J. Selby, C. W. Aikman, J. M. MacKay, M.C., T. Jones, D. Bird, C. Sherris, E. J. Stuckey, A. V. Ledger, C. Murray, R. Jamison, W. Robertson, J. N. G. Nolan, I. Hodgkinson, J. A. Thom, W. C. Stevenson (on ceasing to serve with the Home Hospitals Reserve), J. W. Brown, H. D. Matthews, H. M. Godfrey. Temp. Lieut. J. Black (and retains the rank of Lieutenant).

Lieut. (temp. Capt.) G. E. Spicer, M.C., resigns his commission.

SPECIAL RESERVE OF OFFICERS.

Capt. M. D. Vint relinquishes his commission and retains the rank of Captain.

TERRITORIAL FORCE.

General List.—Capt. (acting Major) F. Scroggie, M.C., relinquishes the acting rank of Major on ceasing to be specially employed.

Capt. W. C. D. Hills relinquishes his commission and retains the rank of Captain.

1st Southern General Hospital: Capt. J. W. Stretton is restored to the establishment.

1st Western General Hospital: Capt. (acting Major) C. T. Holland relinquishes the acting rank of Major on ceasing to be specially employed.

TERRITORIAL FORCE RESERVE.

Lieut.-Col. H. Davy, K.B.E., C.B., from 4th Southern General Hospital, to be Colonel.

ROYAL AIR FORCE.

Major E. C. Clements (R.A.M.C., T.F.) is granted a temporary commission as Major on seconding to the R.A.F.

The undermentioned are transferred to the unemployed list: Capts. C. J. Miner, P. C. Parr, A. Kirkhope; Lieut. W. J. S. Cameron.

Flying Officers to be Flight Lieutenants: T. J. X. Canton, P. McDiarmid.

AUXILIARY ROYAL ARMY MEDICAL CORPS FUNDS.

The usual quarterly committee meeting was held on Dec. 19th at 11, Chandos-street, Cavendish-square, W. Three grants were made in the benevolent branch for officers amounting to £290, and 14 grants in the relief branch for the rank and file amounting to £624. These funds are for the relief of widows and orphans of commissioned officers and non-commissioned officers and men of the rank and file of the Royal Army Medical Corps, Special Reserve, Territorial Force, and New Armies, and also for the relief of the children of those who have been so severely damaged in the present war that they need help for the education of children. Requests for relief should be addressed to the honorary secretary at the offices of the funds at 11, Chandos-street, Cavendish-square, W. 1.

URBAN VITAL STATISTICS.

(Week ended Dec. 20th, 1919.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at 16,500,000 persons, the annual rate of mortality, which had been 13·8, 14·4, and 13·9 in the three preceding weeks, rose to 14·6 per 1000. In London, with a population slightly exceeding 4,000,000 persons, the annual death-rate was 15·3, or 1·9 per 1000 above that recorded in the previous week, while among the remaining towns the rates ranged from 6·1 in Swindon, 7·2 in Southampton, and 7·6 in Warrington, to 20·5 in Hastings, 22·8 in Sunderland, and 23·0 in Dewsbury. The principal epidemic diseases caused 297 deaths, which corresponded to an annual rate of 0·9 per 1000, and comprised 88 from measles, 78 from diphtheria, 51 from infantile diarrhœa, 39 from whooping-cough, 35 from scarlet fever, and 6 from enteric fever. Measles caused a death-rate of 1·7 in Burnley and in Darlington, 2·4 in Preston, 2·7 in Barrow-in-Furness, and 3·3 in Barnsley; and diphtheria of 1·2 in Plymouth. The 64 deaths from influenza were 17 below the number recorded in the previous week, and included 18 in London, 4 in Leicester, and 3 each in Manchester and Salford. There were 2942 cases of scarlet fever and 1822 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, against 2947 and 1796 respectively at the end of the previous week. The causes of 35 deaths in the 96 towns were uncertified, and included 6 in Liverpool, 5 in London, and 3 each in Birmingham and Sunderland.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual rate of mortality, which had been 15·0, 15·3, and 13·5 in the three preceding weeks, fell to 13·2 per 1000. The 281 deaths in Glasgow corresponded to an annual rate of 13·1 per 1000, and included 6 from infantile diarrhœa, 5 from diphtheria, 3 from measles, and [illegible] from scarlet fever. The 86 deaths in Edinburgh were equal to a rate of 13·3 per 1000, and included 3 from diphtheria, and 1 each from measles and scarlet fever.

Irish Towns.—The 133 deaths in Dublin corresponded to an annual rate of 17·1, or 1·8 per 1000 below that recorded in the previous week, and included 1 each from whooping-cough, diphtheria, and infantile diarrhœa. The 185 deaths in Belfast were equal to a rate of 24·1 per 1000, and included 32 from measles, 4 from scarlet fever, and 1 each from enteric fever and diphtheria.

(Week ended Dec. 27th, 1919.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at 16,500,000 persons, the annual rate of mortality, which had been 14·4, 13·9, and 14·6 in the three preceding weeks, fell to 12·0 per 1000. In London, with a population slightly exceeding 4,000,000 persons, the annual death-rate was 10·6, or 4·7 per 1000 below that recorded in the previous week, while among the remaining towns the rates ranged from 3·5 in Eastbourne, 4·9 in Ilford, and 6·2 in Smethwick, to 20·1 in St. Helens, 20·7 in Barnsley, and 26·1 in West Hartlepool. The principal epidemic diseases caused 275 deaths, which corresponded to an annual rate of 0·9 per 1000, and comprised 87 from measles, 82 from diphtheria, 41 from infantile diarrhœa, 40 from whooping-cough, 22 from scarlet fever, and 3 from enteric fever. Measles caused a death-rate of 1·8 in Sunderland, 2·0 in Dewsbury, 2·2 in Burnley, 2·9 in Preston, and 3·3 in Barnsley; scarlet fever of 1·2 in Cardiff; and diphtheria of 2·0 in Willesden. The 43 deaths from influenza were 21 below the number registered in the previous week, and included 12 in London and 3 each in Stoke-on-Trent and Hull. There were 2873 cases of scarlet fever and 1862 of diphtheria under treatment in the Metropolitan Asylums Hospitals and in the London Fever Hospital, against 2942 and 1822 respectively at the end of the previous week. The causes of 30 deaths in the 96 towns were uncertified, and included 3 each in London, Birmingham, Liverpool, and Blackpool.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual rate of mortality, which had been 15·3, 13·5, and 13·2 in the three preceding weeks, rose to 14·8 per 1000. The 316 deaths in Glasgow corresponded to an annual rate of 14·7 per 1000, and included 3 each from measles, diphtheria, and infantile diarrhœa, and 1 from scarlet fever. The 90 deaths in Edinburgh were equal to a rate of 13·9 per 1000, and included 3 each from measles and diphtheria and 1 from scarlet fever.

Irish Towns.—The 92 deaths in Dublin corresponded to an annual rate of 11·8, or 5·3 per 1000 below that recorded in the previous week, and included 2 each from scarlet fever, whooping-cough, and infantile diarrhœa. The 156 deaths in Belfast were equal to a rate of 20·3 per 1000, and included 19 from measles, 3 from scarlet fever, 2 each from diphtheria and infantile diarrhœa, and 1 from whooping-cough.

Obituary.

SIR WILLIAM OSLER, BART., M.D., F.R.S.,

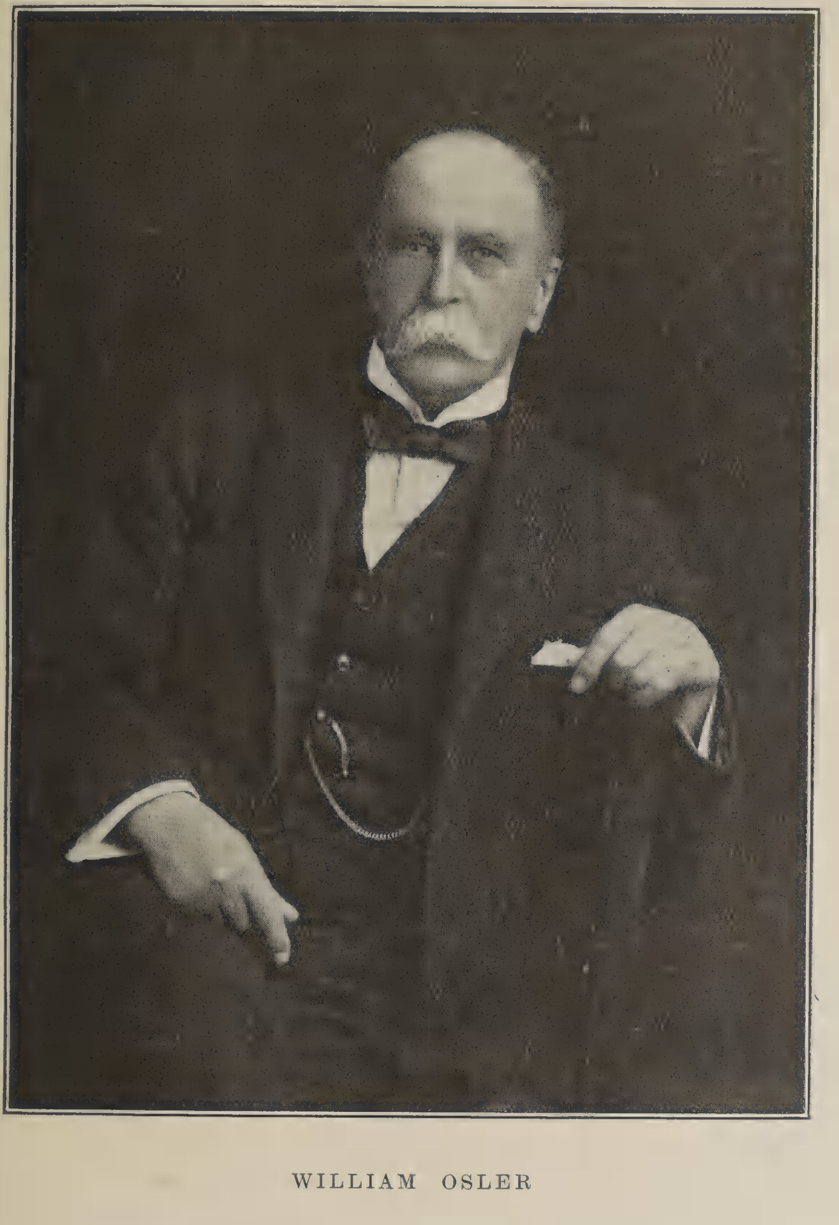
REGIUS PROFESSOR OF MEDICINE, UNIVERSITY OF OXFORD.

WE deeply regret to announce the death of Sir William Osler, Regius Professor of Medicine in the University of Oxford, which occurred on Dec. 29th at his residence, Norham Gardens, Oxford. This sad issue to a long illness had more than once been feared, as bronchitis and pneumonia of an ill-defined type, ensuing upon a chill received three months ago, refused obstinately to clear up. On the other hand, the courage and vitality of the patient, who remained young at the age of 70, flattered his advisers into hope for ultimate recovery. An operation for empyema, performed just before Christmas, promised favourable results, and for a time encouraging reports were issued. The end, however, came suddenly on Monday afternoon.

Sir William Osler was born at Bondhead, Ontario, in 1849, being the sixth son of the Rev. Featherston Osler, a Cornish clergyman who went to Canada as a missionary. The Rev. F. Osler married Miss Ellen Pickford, and their family formed a distinguished group, for two of Sir William Osler's brothers were famous lawyers, one being a judge, while another brother, Sir Edmund Osler, the President of the Dominion Bank of Canada, is a well-known financier. The mother of these sons died quite recently, a centenarian. William Osler was educated at Trinity College School and the University of Toronto, where he began his medical studies. He proceeded thence to the McGill University, Montreal, and graduated M.D. in 1872. Thence he came to London and entered at University College, where he took the Membership of the Royal College of Physicians of London, proceeding immediately to study pathology in the famous schools of Berlin, Vienna, and Leipsic. In 1874 he returned to McGill University and was elected Professor of the Institutes of Medicine, which post he held for ten years, laying thus the foundation of his reputation as clinical teacher and educational authority, and bringing to his work a scientific equipment possessed by but few of his contemporaries. Elected a Fellow of the Royal College of Physicians of London in 1884, he was appointed to deliver the Goulstonian lectures, and in dealing with the subject of malignant endocarditis he became known at once in this country as a great pathologist and clinician. These lectures, which were published in THE LANCET in March, 1885, were, in fact, a revelation of the man. The clinical studies were based on personal experience and the theories were fortified by a wide consultation of the best German, French, and English authorities. The moment the lectures appeared it was obvious that the McGill University possessed a pioneer in our science and art, and it was with great regret that Canada learned that he had accepted the invitation of the University of Pennsylvania to proceed to Philadelphia as professor of clinical medicine. This post he held for five years, and while he added to his academic reputation he also obtained a very large consulting practice.

In the United States a third opportunity now arrived, and one which was to bear still greater fruit. In 1889 he was offered the professorship of medicine at the Johns Hopkins University, Baltimore, a post which he held for 15 years, and here his conduct of the duties laid down a remarkable pattern for university medical education. The ideal at which he aimed, and which he partly carried out at Baltimore, was described many years later by himself when giving evidence before the Royal Commission on University Education in London, presided over by Lord Haldane. Before this Commission Osler pointed out that clinical medicine should and could come directly within the sphere of university training, placing medicine alongside the other great faculties, if certain hospitals were adapted to meet the demands of the scientific study of disease and the scientific training of students. He described to the Commission an ideal hospital unit, showing at the same time that such organisation would place medicine on the footing of other university schools. The unit, according to his description, comprised a professor or director having control of 60 beds and being in touch with laboratories for special research along the obvious lines of physics and physiology, bacteriology and vaccine therapy, chemistry, microscopy, and radiology. While allowing that the hospitals should have a free hand as to details, he made a point that the English system of dressers and clinical clerks should be preserved, as it was proved to have led to training of a more practical sort than could otherwise be obtained. At the Johns Hopkins University he introduced his ideas with perfect success, and to a large extent the new developments in connexion with certain of the great London hospitals are founded on the work done by Sir William Osler at Baltimore. From Baltimore, also, in 1892, there came that most popular treatise on medicine, Osler's "Principles and Practice." This book was recognised at once as a distinct acquisition to medical literature. There were at the time several books, notably those of Taylor, just issued, Roberts, and Fagge, edited by Pye-Smith, which covered the range of medical study to the satisfaction of students and of their examiners, but Osler's treatise appeared at a time when not only did modern developments require recording, but when a new spirit of approach was badly needed in response to altering central conceptions concerning disease. The observation, lucidity, and powers of arrangement, already displayed in the Goulstonian lectures, found full vent in this work. The author contrived to give the lessons to be learned from the latest pathological investigations in combination with admirable accounts of personal clinical observations, while he boldly accepted new theories of disease and new classifications in accordance with the progress of our knowledge. For the first time the student learned the real nature of pneumonia and tuberculosis, and for the first time many practitioners became aware of the real bearing on medicine exercised by modern bacteriological work. In the meantime, from the University School at Johns Hopkins there came a steady output of useful clinical discovery. Osler developed the scientific teaching of internal medicine, and did special personal work in relation to erythema multiforme, chorea, multiple telangiectasis, and polycythæmia, while at his clinic the valuable studies of W. S. Thayer and W. G. MacCallum were conducted into malarial fever, as well as the investigation of amœbic dysentery by Councilman and Lafleur, and other research work which has now found its way into the common stock of knowledge. Osler's work was justified alike by his personal share in its growth, which was rewarded by election to the Royal Society, by his encouragement of coöperators with learning and sympathy, and by the effectiveness of the educational machinery which he had devised.

In 1905 Osler, widely known on the continent of Europe, as well as throughout North America, as a consulting physician, accepted the call of the University of Oxford to the chair of the Regius Professorship of Medicine. His fame was at its zenith, and his departure from America was the signal for an extraordinary outburst of affectionate regret from the medica profession of the western world. Canadian born and o Cornish stock, with his learning reinforced at various European centres, he was a true cosmopolitan, bu America viewed his transference to Oxford as the loss o one who adorned its civilisation. He was just 55 years of age, and a better man to succeed Sir Henry Acland and Sir John Burdon-Sanderson could not possibly have been found. He was a scientific student and teacher o acknowledged rank, and he had an enormous acquaintance with men and things, great practical experience in education, and definite ideals whose working success had been proved. And those ideals were exactly i connexion with the position which a faculty of medicin ought to enjoy if it were to take its stand in university training with the other great faculties. He found a Oxford a final opportunity. By his position as physicia to the Radcliffe Infirmary he enjoyed the facilitie for combining clinical practice with scientific researc and academic exposition. His students were men fitte by preliminary education to get value from his teaching



WILLIAM OSLER

and he made the medical school at Oxford a living force. He kept the Oxford medical graduates in touch with their University in a way that had not hitherto been attempted, and he used his personal qualities and his open-handed hospitality to further the scientific interest of the University and its medical school. Never was professor less professorial, never was don less donnish; yet never did the ancient University of Oxford summon to her side a man more appreciative of all that a great university stands for.

One of his eminent colleagues at the University thus writes of Osler's Oxford life: "After the strenuous hustle of American life the rest and calm of Oxford appealed to Osler, and it is good to know that the years spent here were amongst the happiest of his life. The surroundings were such as he delighted in, the society was congenial, and the duties of his office, not overburdensome, were such as to give him ample scope for his activities and free play for his broad outlook on life. Gifted with a remarkable memory and equipped with an almost limitless experience, he never seemed to forget anything he had either seen or read. He had a marvellous power of marshalling facts and getting at their essentials. Quick to realise the ever-changing needs of the times and always in the front of progress, there was a brightness and sparkle about his views which disarmed opposition. At a meeting, whenever Osler was in the chair, the proceedings were never dull, and business was usually expeditiously transacted. He had clear views as to what he wanted, and generally got his way, for his way was usually the best. Of a nature most generous and kind, he was ever mindful of the trials and sorrows of others. Many will there be who remember with affection the comforting words with which he soothed their sorely tried hearts. To those engaged in the struggle of life he was full of encouragement, wise counsel, and often substantial aid. Even of the failures in life he had always something good to say. With qualities such as these it cannot be wondered that he endeared himself to all, and we in Oxford will cherish the memory of his sympathetic personality.

His delight was in books; he was never happier than when showing you some recently acquired treasure. Much of his leisure was spent in the Bodleian, of which he was a curator, and his expert advice was of invaluable service to the delegates of the Clarendon Press. By virtue of his office he was master of the quaint old almshouses at Ewelme. Nothing gave him greater pleasure than to whisk off by motor-car a party of American visitors—there, possibly, for the first time—to introduce them to the beauties of this most picturesque of English villages; it remains as a lasting memory to many who were privileged to make the visit.

Of his work in the medical school, what can be said that is not known? He cheered us by his breezy presence and left us all the heartier with some quaint quip or jest. None the less, he was alert and observant, and oftentimes we benefited by some shrewd remark or friendly criticism.

It was around the Radcliffe Infirmary that his activities mainly centred; he was largely instrumental in getting the new clinical laboratory built there, and much of his time was devoted to the introduction of appropriate clinics in that institution. Like many others, Osler lost his only son, and the blow hit him hard, but he never winced. He said to me: 'Ours is a common sorrow; we must think of others as well as ourselves.' In consequence he immersed himself in duties innumerable, particularly in connexion with the hospitals under Canadian and American control. He was always responsive to the appeal of friends from abroad who were anxious to obtain news of their wounded sons. This often entailed long and tedious journeys, and the strain told on him. He was a worn and tired man.

When peace came, bringing with it the brighter outlook, a holiday in the Channel Islands appeared to have restored to him all the old vitality—under the genial influence of the Jersey climate, with boyish glee he had been turning cart-wheels on the sands at 70 years of age. We all hoped that 'our Regius' had still many years of active life before him. Called in consultation to Glasgow he was caught by the railway strike; he managed to travel as far south as Newcastle, and there he was held up. Anxious to get home he undertook the long motor journey to Oxford. He arrived a sick man, and despite the care and devotion of those who attended him so lovingly and long he passed away with the fading light of the afternoon of Dec. 29th."

The war made of Sir William Osler a link between the medicine of America and Canada and that of the Allies. His presidency of the Fellowship of Medicine was inevitable when the purposes of that organisation became defined, for that in medicine we have the strongest bond between nations, now an obvious proposition, was always to him a creed. As his Oxford colleague has said above, he worked heart and soul for the sick and wounded in the great struggle. His counsel and his purse were ever open to those who needed them—any need of any sort appeared to constitute a claim which was sure to be honoured—and his Oxford home, like the guest-room at the Athenæum, with him as host, became a centre of frequent and wide reunion. He enjoyed bringing men together, and not only did his guests feel a personal regard for their host, but his lovable example compelled them to think well of each other.

We need not enumerate in detail either the books which Sir William Osler wrote, or the academic distinctions which he enjoyed. Probably no man ever had the right to wear so many hoods. An Honorary Doctor of Science in five British universities, he was an LL.D. seven times over, while Berlin, Vienna, and Christiania added to the long list of English, Irish, Scottish, Canadian, and American degrees. He was created a baronet in 1911. His published work includes, in addition to the "Principles and Practice of Medicine," lectures, monographs, and addresses on many clinical manifestations and affections, several volumes of essays, of which "Æquanimitas," published in 1904, is the best known, and many biographical studies, of which those on Linacre and Servetus are admirable examples of the intimate historic style. He was also, with Dr. Thomas McCrae, the editor of a well-known System of Medicine, in the production of which leading physicians in this country and the United States and Canada coöperated.

The medical profession has lost in Sir William Osler an acknowledged head; the east and west of the Anglo-Saxon worlds have been deprived of their firmest common friend; and the individuals who mourn him to-day stand in every class not only in this country and in America, but throughout our Dependencies and the Continent of Europe.

Sir William Osler married in 1892 Grace, the daughter of John Revere, who survives him, and by whom he had an only son who predeceased him. The sympathy of the world goes out to Lady Osler.

CHARLES LOUIS TAYLOR,

LATE ASSISTANT EDITOR OF THE "BRITISH MEDICAL JOURNAL."

Charles Louis Taylor, for many years on the staff of the *British Medical Journal*, and for 20 Assistant Editor, died after a long illness on Dec. 21st, in his seventy-first year. He was the only child of Dr. Charles Taylor, of Peterhead, Aberdeenshire, who died of cholera contracted in the course of duty, at the age of 24. The mother took her infant son to France, and when he was brought again to Scotland the child could speak only French. He entered Blair's College, Aberdeen, at the age of 11, and from there, at the age of 15, went to the Scots College, Valladolid, to be educated for the priesthood. Finding that he had no vocation, he thought of entering the Indian Civil Service, but when he applied he was over age. At about this time he lived a good deal in France and this upbringing made him a considerable linguist. He had colloquial French, Spanish, and Latin, a good knowledge of Portuguese and Italian, and afterwards taught himself to read German. He entered as a medical student at University College in 1873. Though he was punctual in his attendance throughout the full curriculum and eventually, as locum-tenent, held resident posts at University College Hospital, he could never be induced to sit for any examination. Thus, though he was well read in medicine and had had considerable practical experience, he never qualified. In 1880 he became secretary to Sir Morell Mackenzie and assisted him in the preparation of the second volume, published in 1884, of his "Manual of Diseases of the Throat and Nose," of which the first volume had appeared in 1880. In the preface to the latter the author acknowledges his "deep obligation to Mr. C. Louis Taylor for his invaluable help." It was, no doubt, in reference to similar help rendered to other medical authors, so often anonymous and thus unrecognised, that he adopted for his book-plate the legend "Alas, poor ghost!"

In 1886 Taylor joined the editorial staff of the *British Medical Journal*. In 1897 he was appointed Assistant Editor, and to his duties in that capacity the remainder of his working life was wholly devoted. In the routine work of medical journalism he was accurate and painstaking almost to a fault. A misquotation or wrongly applied name really distressed him, and his own work was a model of accuracy and logical arrangement. The pleasure he found in his calling was in two directions. He was a skilful and effective controversialist, and loved nothing better than to quench an antivivisection or antivaccinist light with the cold douche of fact and common-sense. His real strength was in medical history, especially biography, in the study of which he found recreation as well as occupation. He edited the volumes published under the general title "Masters of Medicine," and made preparations to contribute a biography of Vesalius, but the series was discontinued. Most of his historical writing was published in the *British Medical Journal* without his signature, but his attainments became known to a few, and some years ago, at the instance of Sir William Osler, he was elected an honorary member of the Section of the History of Medicine of the Royal Society of Medicine. This recognition greatly pleased him, but public functions had no attraction for him. He was of a genial nature and his courteous manner quickly put a stranger at ease; he loved his work and his books, and his home life above all.

He enjoyed good general health until about seven years ago, when he had a serious illness. A successful operation by his old friend Mr. Bilton Pollard gave him a new lease of life, and he returned to work, fighting manfully against disabilities and failing energy, until his retirement in March, 1917. He married in 1882 and leaves a widow, two daughters, and a son, Dr. C. J. G. Taylor, of Nuneaton, who served throughout the war as surgeon, R.N. Reserve (Vol.).

CHARLES ROBERT WATSON, M.D. BRUX., M.R.C.S., L.R.C.P. LOND.,

SURGEON, TUNBRIDGE WELLS GENERAL HOSPITAL.

THE death of Dr. C. R. Watson, of Tunbridge Wells, occurred quietly in his sleep, the result of heart trouble, on Dec. 23rd, 1919. He was the elder son of Dr. George S. Watson, and the grandson of Dr. Trustram, both of whom had practised in Tunbridge Wells before him. Before beginning his medical education at St. George's Hospital he had been at Tonbridge School. At the hospital he was a keen clinical student, always in the wards, and always ready to discuss his cases. He held the offices of house surgeon, house physician, and obstetric assistant, and having qualified as M.R.C.S., L.R.C.P., afterwards took the M.D. degree at Brussels. Almost immediately he joined his father in the Tunbridge Wells practice, where his life work has been.

Dr. Watson's early death is a direct result of overwork during the war. In addition to double work in his practice—for his brother volunteered—and at hospital, he was surgeon to a large Red Cross hospital, a venereal clinic, a large Church of England Home, and convalescent homes for children and for officers: work which led to straining his strength very seriously. Few people realise the enormous amount of work which the civilian members of our profession have undertaken during the war. Much of this work was unremunerated and done for love of country, with determination to accept no reward or decoration. Such work was Charles Watson's.

Correspondence.

"Audi alteram partem."

THE ANTI-RELAPSE TREATMENT OF MALARIA.

To the Editor of THE LANCET.

SIR,—When Naaman the Syrian was advised to wash seven times in the Jordan in order to be recovered of his leprosy he was angry at the mere simplicity of the prescription, and apparently for the same reason many medical men still refuse to treat their cases with the very simple continuous quinine medication laid down by the malaria prophets in Israel. May I argue the case once more?

The first formula which we suggest or use at the large consultative Tropical Diseases Clinic, which was started by the Ministry of Pensions near Sloane-square on Oct. 1st last, is the following:—

To Messrs. ———
For Mr. ———
℞ Quininæ sulphatis... ... ... gr. 80.
Ac. sulph. dil.... ... ... q.s.
Aquam ... ... ℥ viii.

Solve. Half a sherryglassful (2 tablespoonfuls or one-eighth of the bottleful) every day just before breakfast without fail. The bottle to be refilled once a week for more weeks.

This solution (with pharmacological precautions, understood) is perhaps the most widely used medicine in the world, not excepting Dover's powder, and I quote the prescription merely to make the directions quite clear. Dr. Castellani reminds me that it is often called "coolies' mixture." It has been employed everywhere in warm countries since Pelletier and Caventou isolated quinine from cinchona bark in 1820.

We employ it as follows: (*a*) If at his first visit the patient complains of relapses within the last few days or weeks, or looks ill, or is a complicated case, or is apparently not to be trusted to take his medicine, we suggest or prescribe enough quinine for only one or two weeks, after which he must present himself again for examination (whether the parasites be found or not). But (*b*) if he appears to be trustworthy and not much "out of sorts," we tell him to return after four weeks, and we enter the word *three* before the two last words in the directions, so that he can get his medicine regularly from the chemist without troubling to see his doctor again in the meantime. In both cases, however, the patient is always told that if he does get a relapse in spite of the treatment he should take three doses (instead of one dose) a day just before meals for two days at least, and should see his doctor again as soon as possible.

Few such cases occur, and the patients are generally found to be much improved at the second visit. They are then given enough quinine for another month (the same prescription), after which they must report again. At this third visit they generally admit having remained quite free from relapses since the second visit, and look still better; but it is advisable to continue the medicine for yet another month if possible, making 9 to 12 weeks of 10 gr. of quinine daily. The men, who soon recognise the benefit of the daily dosage, are usually quite willing to continue it for this period. At the fourth visit I am now stopping the quinine, as a rule, or reducing it to 5 gr. a day for another month; but I explain to the patient that this may possibly involve a relapse, after which the whole treatment must be commenced again; and I request him to report immediately if such a relapse threatens. We have not yet had time to ascertain the final results but I infer from 40 years' general experience that when once a case is restored to ordinary health and vigou his infection will either be cured, or he will possibly suffer only from an occasional relapse after long intervals of six months, or a year, or more. But thi remains to be proved statistically. When I myself was infected during my malaria investigations in 1897, took quinine precisely as prescribed above for fou months (except, of course, that I took larger doses at first), and I have never had a relapse.

As shown at the malaria concentration centres, relapses may not infrequently occur during the first two or three weeks of this daily dosage, or very rarely after longer periods; but the large majority of the men improve greatly under it in a month. If, therefore, a case fails to improve within a month, it is most probable either that he is not taking his medicine (for which we have a known test), or that he is suffering from something else than malaria.

We employ the sulphate for economical reasons. It agrees with the large majority of the cases. I am now taking the medicine myself in order to keep company with my patients, and I scarcely know afterwards whether I have had a dose or not. I prefer the dosage *just* before breakfast in consequence of large personal and general experience, partly because the first mouthful of the meal removes the taste, and partly because I think the drug is most effective when given at that time and in that manner. Several patients who complained that it made them sick were, I found, taking it half an hour or more before the meal—quite another matter. When it really does not agree (as with dyspeptics) I allow half the dose before an evening meal or substitute the hydrochloride.

The single dose before breakfast is more convenient for working men than two or three smaller doses during the day. A dose of 30 gr. twice a week would probably be as effective, though not more so, but the men would not take it. On first visits most of the men have been taking quinine only when they "get fever" in doses from 5 to 30 gr. and omitting it entirely between the relapses—for which reason the said relapses occur. The thing is to persuade them to take it daily. We employ several kinds of pleasant peaceful persuasion—and the great majority of our patients are good honest men who wish to get rid of their malaria, pension or no pension. Thus I point out to them that it is bad military tactics to shell their enemies, the "germs," only when these are attacking them during a relapse; we should go on shelling them after they have been driven back to their trenches in order to exterminate the lot before they can bring up reinforcements. Another pleasantry of mine is to say, "Please give my compliments to your wife and beg her to make you take your medicine every day *whether you like it or not!*" They appreciate the situation; the wife gets the message, and the patient comes back smiling a month later—a better man.

I doubt whether quinine is as certain in tablets as in solution. For a month or a fortnight after relapses 15 gr. daily are perhaps better than 10 gr., but the latter probably suffice for the remainder of the three months' course—as was found to be the case in the two divisions brought from Salonika to France in 1918 (see THE LANCET, 1919, i., 780, where I also summarised some of the results in two Malaria Concentration Centres). The 15 gr. daily treatment is advocated in the excellent recent paper (THE LANCET, ii., 1134) by Dr. Henry Fraser —who has had a very large experience in the malaria centre on Salisbury Plain and in two malaria hospitals, and who is now a member of our clinic. I doubt whether *less* than 10 gr. a day is sufficient, judging from Lieutenant-Colonel S. P. James's results at Epsom in 1917, and other work. We tried *no* quinine between the relapses in two hospitals in 1917, with very bad results. But perhaps the body weight and other characteristics of patients ought to be more considered with reference to dosage than it has been possible to consider them hitherto.

The parasites are always searched for in Dr. Broughton Alcock's laboratory at the first visits of patients, and at subsequent visits if no improvement is shown, or if the diagnosis is doubtful. A course of quinine is sometimes advised as a precaution, even though no signs of malaria may remain. A fortnight's rest may be enjoined after a serious relapse, but the patient should gradually return to full work as he improves—idleness is the worst thing possible in chronic malaria, in hospital or out of it. Tonics, fruit, stout, laxatives, &c., are to be employed at discretion.

What is the scientific basis for this class of treatment? It has been employed under various forms since cinchona was first introduced. In military practice in India before the war six weeks was the official duration. I have always advocated four months (see my "Prevention of Malaria," Murray, second edition, p. 142). "Two months from date of the last relapse" was ordered in the Provisional Instructions for the Treatment of Malaria (War Office, August, 1917). But the most striking example—in fact, I think the most brilliant piece of malaria work during the war—was the case, just referred to, of the two Salonika divisions in France. They arrived so "rotten with malaria" that they shed a third of their men in wayside hospitals between Marseilles and Dieppe, and 100 men or more were coming to hospital every morning out of each depleted battalion. In three months almost the entire two divisions (which had gathered up their men again) were in the front firing line in France!—a result due to the vigour and ability of Lieutenant-Colonel J. Dalrymple, C.M.G., O.B.E., acting under the orders of General Sir C. Burtchaell. As the result of this experience malaria concentration centres were formed in each command in the United Kingdom, but only one month's quinine course was (officially) given in these. Comparatively few of the men from these divisions and centres are now coming to us; and I wish that the whole War Office malaria organisation could have been retained for the use of the demobilised soldiers. It therefore now remains for civilian medical practitioners to apply the same method to these.

But can we not cure the cases outright by some *therapia magna sterilisans?* I wish we could. Unfortunately, though the War Office made innumerable experiments from early in 1917 onwards, no really satisfactory result was obtained. For details the reader should study the forthcoming War Office publication, Observations on Malaria, by Medical Officers of the Army and Others (Stationery Office), the Annals of Tropical Medicine and Parasitology (Liverpool) for the last two years, and many papers in THE LANCET and other journals. We tried intravenous and intramuscular injections, heroic doses, kharsivan, and almost everything we could think of. Not one treatment provided a certain cure; and the treatments which gave the most promising results required at least a month's stay in hospital and were, I think, almost more severe than the disease. We still live in hopes; but up to the present the daily dosage described above remains the best, as it is the oldest used. If I had malaria to-day I should not dream of allowing any other "cure" to be practised on me.

Much is being written just now on treatment, but most of it applies only to the treatment of relapses. As will be seen from the "Observations," almost any reasonable quinine therapy reduces the relapse in a day or two; but our present point is that relapses ought not to be allowed to occur at all. In the great majority of cases, if a relapse occurs we may be sure that the patient has not been taking his quinine, either in sufficient doses or sufficiently frequently, or both. I quite agree with Colonel James's remarks on this point (THE LANCET, Dec. 6th, 1919, p. 1017); and many of the numerous deaths he mentions were probably due to this fact. Yet surely enough has been published on the subject.

Are we, then, to continue this anti-relapse treatment for ever? I infer that the malaria infection tends to exhaust itself and to die out more and more rapidly after the first year. When I was at the War Office I estimated that from 100,000 to 150,000 men had become infected on the Eastern fronts, but James says (p. 1016, loc. cit.) that only 14,000 patients have been notified to the Ministry of Health since March 1st. This is only half the number of Y-scheme men alone (obstinate chronic malarias), which, to my certain knowledge, have been sent home from Salonika. What has happened to the remainder? Recovered, I hope. And I trust that most of the others, except perhaps a few "wanglers," will be off the books long before this time next year.

I am, Sir, yours faithfully,

Dec. 25th, 1919. RONALD ROSS.

THE DRAFT REGULATIONS FOR 1920.

To the Editor of THE LANCET.

SIR,—Dr. J. Pereira Gray's letter in your issue of Dec. 27th, 1919, reveals him as the obstinate twelfth juryman. To maintain this attitude it is necessary either to pervert the facts or to attribute to other minds the psychological imperfections of one's own. Dr. Gray does both. By what appears to be the general opinion of those present the recent Conference of Representatives of Local Medical and Panel Committees was the most satisfactory of a considerable series of such conferences because (1) relatively full opportunity was given for the discussion of all important matters; (2) the items were as far as possible taken in what seemed to the meeting to be the order of importance; (3) after full consideration it was possible to arrive at unanimous or almost unanimous decisions to present to the Ministry of Health on behalf of the profession as represented. That Dr. Gray does not agree with these decisions does not prove that they were foolish. He should not, however, misrepresent those decisions or give, as he does, an entirely erroneous impression as to the character of the conference.

Almost every sentence in his letter which purports to be a statement of fact is either false or misleading. I quote seriatim the most important of them.

1. "The Local Medical and Panel Committees have proclaimed him"—the Minister of Health—"autocrat in medical affairs." 2. "A resolution to organise the profession to refuse service under certain contingencies was dropped as unthinkable." 3. "We agreed to negotiate with the Government for a pension scheme." 4. "When there are enough practitioners to go round, it"—the practitioner's list of insured persons—"will be limited to 2000." 5. The insurance practitioner "must place himself at the beck and call, night and day, of anyone who demands his services." 6. "If he would employ an assistant he must ...... agree to the terms the committee imposes." 7. "The patients whom he attracts ...... are not his, but belong to the State."

Not one of the above statements is true. This being the state of affairs with regard to the facts, there is no need for me to say anything to controvert the opinions which, presumably, are based upon them. Dr. Gray has, of course, a right to hold whatever opinions he chooses, but if he offers them to the public he should verify his facts, and he should refrain from attributing improper motives to the general body of his colleagues, all of whom have the honour and interests of the profession at heart to at least as great a degree as he has, I doubt not, himself.

I am, Sir, yours faithfully,
HENRY B. BRACKENBURY.

Stroud Green, N., Dec. 27th, 1919.

To the Editor of THE LANCET.

SIR,—Does Dr. Addison expect that the "general practitioner will be efficient and content" if payment under the new regulations is less than what is the general desire of the profession, especially if, under the same regulations, the Ministry of Health takes from us the proprietary right in our practices? Dr. Addison is reported by you to say that "at present no measure was available of the extent of work in treating the demobilised man." I would suggest one. If Dr. Addison, who is a qualified medical man, will only do a three months' "locum" in any large industrial centre he will soon find what the calls of the demobilised man mean to the profession. What matters it to the medical profession that the Government is committed to the increased expenditure mentioned by Dr. Addison? Would it be a satisfactory excuse for a man to refuse to pay his butcher or grocer on the ground that he had promised to buy his wife a diamond tiara or his son a Rolls Royce car? That, we can see, is monstrously absurd, and irrespective of any commitments of the Government it is to be hoped that the profession will stand out for the 13*s.* 6*d.*

I think the deputation that met the Minister ought to have dealt with the proposed theft of our practices. Why should a man who has bought his practice, or on who has struggled hard to build up his practice and ha to economise in the extreme to make ends meet durin the earlier years of his professional life—why shoul these men be compelled to "stand and deliver" at th instigation of any Government department? Even chimney sweep or a rag-and-bone man can sell th goodwill of his round. Are the medical profession to b treated as outlaws—people who have no claim to an protection?

The whole disgraceful thing is due to the comparativ fewness of our votes. We cannot turn an election, bu *we can strike* by coming off the panel. Let us unite an do so, unless we get fair remuneration and retain th proprietary right of our practices.

I am, Sir, yours faithfully,
D. FENTON, M.B., Ch.B., D.P.H.

Blackburn, Dec. 20th, 1919.

CONGENITAL DISLOCATION OF THE HIP.

To the Editor of THE LANCET.

SIR,—Mr. A. H. Tubby's note in THE LANCET c Dec. 20th, 1919, on the treatment of refractory cases c congenital dislocation of the hip raises a very importan question, and one on which the opinions of surgeon differ widely—namely, up to what age should reductio be attempted? It has been a source of some surpris to me to find how many surgeons regard age by itself a no contra-indication to attempted reduction. On th other hand, there is a large—and I am inclined to thin a larger—number of surgeons who will not operate afte a certain age is reached.

Experience seems to me to be strongly in favour c not operating upon unilateral cases after 10 years c age and bilateral after 6 years. As the age-limit i approached reduction becomes increasingly difficult an the risks proportionately greater, while the prospect c a perfect result becomes smaller. When the age-limi is exceeded the results, in my opinion, do not warran the risks, immediate and remote. I am convinced tha actual harm may result, quite apart from accident during attempted reduction, of which the ill-effects ar usually temporary. The pain and disability from whic these cases sooner or later suffer, and the expectation c which is the chief indication for operation, are, I thin attributable to osteo-arthritic changes occurring in th deformed joint. Unless a permanent anatomical reduc tion has been achieved the traumatism to which th joint has been subjected may, and in the older cases ver often does, hasten the onset of those very changes i the joint which the operation was meant to avoi Again, even though an anatomical reduction has bee obtained in a case near the age-limit, changes in th joint occur which I have been accustomed to speak c as "absorptive arthritis," and which lead to a gradua wearing away of the head and neck of the femur, an sometimes the formation of a migrating acetabulun both of which may result in gradual re-dislocation.

It is admitted by some of those who attempt reduc tion at any age that an anatomical cure in cases abov the age-limit is uncommon, but they say they obtain a "anterior reposition," with improvement in the stabilit of the joint and the gait of the patient. My exper ence of "anterior reposition" has been extremel limited—far more limited, it would seem, than that c some surgeons. If an anatomical cure does not resul the bones, as a rule, return to their former position- i.e., there is an unquestionable relapse. I venture t suggest that those who advocate treatment of thes cases after the "age-limit" has been exceeded, shoul produce their late results, so that those whose exper ence has forced them to abandon operation in the old cases may be convinced of their error.

As regards open operation, this may be resorted t with two separate and distinct objects: first, to obtai an anatomical reduction; and second, to preven "relapse" in a hip already reduced. I agree with M Tubby that the former operation should only be resorte to after the bloodless method has failed, but I cann agree with him as to the wisdom of thereby raisin the "age-limit." The younger the case that resist anipulative methods, the stronger, to my mind, is the dication for open operation. Conversely, the nearer e age-limit is approached, the greater the care ecessary before deciding to subject the patient to e extra risk of an open operation. Since Burghard mphasised the importance of the ilio-psoas, and ecommended the division of this tendon in papers ublished in 1901 and 1903, I have invariably severed as a part of the open operation for reduction of congenital dislocation. As regards the second operation, I ink this is particularly indicated in a case in which revious bloodless reduction has been accomplished, ut has been followed by relapse, and which is still oung enough to stand a good chance of a cure esulting.

The method I have adopted with success has differed om Jackson Clarke's in that the joint is not opened. he periosteum is incised parallel to and about a third f an inch above the acetabular margin, and a flap of his membrane is *roughly* rugined down till the cotyloid gament is reached and elevated from the acetabular argin. A few stitches are inserted to keep this flap urned out from the bone, and also to take in the slack the upper part of the capsule. A more certain result hould be obtained by making use of some form of bone raft. These procedures are not, in my opinion, justified t and above the age-limit, nor should either be made se of till the possibility of obtaining a satisfactory esult by means of the bloodless method has been arefully excluded.—I am, Sir, yours faithfully,

Dec. 23rd, 1919. H. A. T. FAIRBANK.

COPPER ALANIN IN INOPERABLE CANCER.

To the Editor of THE LANCET.

SIR,—In your issue of Dec. 13th, 1919, appears a etter under this title from Dr. James Donelan, referring o a case of inoperable cancer of the tongue in which e has obtained distinct palliative results by the employ-ent of copper alanin, the use of which in protozoal iseases and in inoperable cancer was suggested and its ack of toxicity in proper dosage demonstrated by me.[1]

I am glad to note that Dr. Donelan rightly does not laim a curative action, as his result in this respect orresponds with those obtained by myself and other bservers who have been sufficiently interested in the linical action of copper alanin. Mr. Aslett Baldwin, vho has been kindly making investigation on the use f copper alanin in a considerable number of cases of ancer and keeping me acquainted with the results, as not yet been able to come to any conclusion efinite enough to bring forward. It would be a great ity for false hopes to be aroused in such a matter, and may remark that the only case in which to my nowledge the use of the substance has been followed y apparent recovery has been in which copper alanin vas not employed alone but conjointly with other reatment, the effect of which has not been sufficiently nvestigated to warrant publication.

I am, Sir, yours faithfully,

J. A. SHAW-MACKENZIE, M.D. Lond.

Cumberland Mansions, W., Dec. 29th, 1919.

THE PLACE OF THE PHYSICIAN IN OPHTHALMOLOGY.

To the Editor of THE LANCET.

SIR,—I have read with very great interest Dr. Rayner . Batten's article in THE LANCET of Nov. 29th, and also our leading article in that of Dec. 13th. It will probably e agreed—internally if not avowedly—by most ophthal-nologists that Dr. Batten has expressed opinions and nade criticisms which are true and to the point—amely, that sufficient justice is not done by the verage ophthalmic surgeon to those numerous patients vho are distinctly in need of purely medical as opposed o surgical treatment, and that the consulting physician loes not meet the requirements. The ophthalmic urgeon can hardly be expected to keep abreast of both medicine and surgery and also to apply them both to ophthalmology, and it seems safe to state that he does not do so. In the present crowded state of the ophthalmic clinics how many of these purely medical cases receive sufficient attention from anyone concerned? One has simply to name syphilitic, tuberculous, and arterio-sclerotic conditions of the eye to call up a host of cases which have been seen and which conscience whispers have not received full attention and consideration. As you, Sir, indicate in your article, Dr. Batten's remedy may not be the best remedy, but it is clear that, by some means or other, the present system, in accordance with which very large numbers of medical cases are supervised, where not actually treated, by men who are essentially trained surgeons—often enough with no leanings towards medicine—should be amended in such a way as to place the medical eye patient attending an eye clinic in as favourable a position as his fellow-sufferer who attends the medical side of a general hospital for a disease of some other part of his body. Even in private practice the purely medical case is apt to be at a disadvantage, for the conscientious ophthalmic surgeon will refer him to a physician whose fees must be paid. Doubtless there is the family practitioner, but as he in most cases is not familiar with the ophthalmoscope, the patient is tossed about from one to the other very much to his own disadvantage. Why not therefore the physician oculist as well as the surgeon oculist? But, between the two, where does refraction come in?

I am, Sir, yours faithfully,

Bothwell by Glasgow, Dec. 22nd, 1919. ERNEST THOMSON

THE LIMITATIONS OF SCIENTIFIC THOUGHT.

To the Editor of THE LANCET.

SIR,—Dr. Harry Campbell, in his lecture on Mental Personality, in your issue of Dec. 27th, 1919, states that space "is acknowledged by all philosophers to be a mode of perception." This statement, as it stands, is inaccurate, as all philosophers have not by any means acknowledged this. Apart from the history of thought on this subject, the fact that Kant had to plead for his theory (that space is a mode of perception) that it "should gain favour as a hypothesis worth entertaining" is enough to show that eighteenth-century thought needed much conversion.

Dr. Campbell's remarks on the restriction of science to its own business are good reading, and advice on this point is always timely. I fear that Professor Karl Pearson, whose "Grammar of Science" he quotes, is one of the chief sinners in this regard, as he confuses the boundaries of science and philosophy, and writes mostly from a subjectivist standpoint, without seeming to realise that he has thrown overboard the "method of science" with which he started. Burdon Sanderson, somewhere in his essays, has the excellent remark that the physiologist can pursue philosophy if he has the talent for it, but must understand that the moment he enters the field of philosophy he leaves his tools behind him. It is unfortunate that these limitations, so well indicated by Dr. Campbell, are often ignored by men of science in their writings, the result being calculated to divert those who know, but merely to befog the unsuspicious reader, who will probably put the blame on his own intelligence.

I am, Sir, yours faithfully,

Liverpool, Dec. 28th, 1919. EDMUND HUGHES.

NEWINGTON v. HOLMAN AND WIFE.

To the Editor of THE LANCET.

SIR,—Referring to your account of this case in your issue of Dec. 20th, 1919, I am surprised that you failed to realise that, probably for the first time on record, lay opinion on a question of medical ethics and practice has overridden testimony offered by an expert and uncontradicted by any other competent witness. When I stated in court that it was the custom in our profession—in the absence of physical signs *pathognomonic* of general paralysis of the insane—to have more than one Wassermann test done before making a definite diagnosis, which involves an implicit stigma of antecedent syphilis, I was uttering not merely a pious opinion, but a fact familiar to all bacteriologists, and not likely to be disputed by any experienced physician. In omitting to verify this fact before giving his judgment Mr. Justice Sankey has—unwittingly, I am sure—created a most unfortunate precedent which he would probably be the first to deplore.

Topsham, Devon, Dec. 28th, 1919.

MEDICAL STUDIES IN LONDON:
POST-GRADUATE TEACHING.

To the Editor of THE LANCET.

SIR,—It may seem to be an inauspicious act and one rather resembling the loud proclamation of odoriferous fish to draw attention away from the enthusiasms to the prosy subject of the difficulties that lie in the way of the institution of post-graduate teaching in London of a style and dignity worthy of the metropolis of the British Empire. But in the many letters, articles, speeches, and other forms of propaganda now prevailing the existence of these difficulties seems to be ignored or overlooked until the impression left on the mind of the outsider can only be that the London schools and hospitals are afflicted with a double dose of the native English lethargy, and have hitherto failed in an important duty through sheer laziness. Without altogether denying that we have been slack in these matters, nevertheless I propose to notice several factors in the situation which, unless they are recognised and remedied, or removed, will go far to render the best laid scheme of post-graduate teaching incapable of holding its own with those of the large continental centres, and especially with that of Vienna, where, we are told, before the war American students used to spend as much as £40,000 per annum. It is with Vienna that London proposes to compete.

Now, what are the difficulties in the situation? In Vienna, as in London, the real teaching—the teaching that counts—is in the hands of the junior staffs of the hospitals. But in Vienna these men, apart from their hospital duties, do nothing else but teach. They live and work in and for and by their hospital and their teaching. They are not allowed to carry on private practice. In a word, they are professional and whole-time teachers. It may be said, however, that such a class of medical tutors is also to be found in the British hospitals and schools. That is true. Such a class does exist here. But it is very much smaller numerically than in Germany and Austria; and, moreover, with us such men are not devoting their whole time to the training of post-graduates in one special department of medicine or surgery. They teach undergraduates, in whose hands rests their future. Or else (it may be at the same time) they occupy themselves with coaching men who are reading for the higher degrees and qualifications, such as Fellowships and Memberships of the Colleges and Doctorates of the Universities. And the work for these higher examinations is, for the most part, general medicine and surgery.

And this brings me to my second point, which is, that abroad the British system of higher qualifications in general medicine and surgery is unknown. On the continent as soon as the general qualifying examination is over specialisation can begin. If a man is going to join the specialist or consulting class of practitioner he devotes his whole time to his specialty. And in Vienna he lives by teaching it. In England specialising is usually deferred until the higher degree or qualification, or both, has been attained. Thus, to take the most familiar example in London, the English Fellowship in Surgery occupies, as a rule, several years in a man's twenties, and sometimes, indeed, it eats into his thirties before he begins seriously to specialise and to teach his specialty. Or, if he has already begun to specialise, the severe course of study necessary for the Fellowship causes an interruption in his special training. Thus the teacher in England is handicapped beside his foreign competitor in: (1) being in private practice; or (and) (2) being a tutor of undergraduates in some preliminary subject; or (and) (3) being himself deeply immersed in general reading for his own higher qualifications. I am aware that recently the universities have been showing a tendency to recognise special subjects in their higher examinations, but the colleges (in England that is) do not yet do so.

So much for the teacher, whose position could easily be improved by a wise rearrangement of examination subjects. We turn now to some other dominating factors.

In Vienna the opportunities for the foreigner to gain skill and experience in operating are very much greater than they are in England, and for two reasons: first, because there is no public (or private) opinion against allowing inexperienced men to operate on hospital patients. The ear clinics of Vienna are full of patients with facial paralysis following mastoid operations performed by foreigners. This difficulty we are proud enough to look in the face and to submit to it. No English hospital surgeon would ever wish it removed. Secondly, and this difficulty, on the other hand, could be removed, but only by legislation, the working of the Anatomy Acts, and, above all, the recent scarcity of subjects render it impossible for teaching centres to obtain bodies for operation. The deficiency will no doubt be remedied in time, but even then further facilities will be required before post-graduate training can become at all what it should be. What is needed is the power for the special hospitals and special clinics of the general hospitals to obtain bodies for the teaching of their own special operative work, and this applies particularly to the highly delicate and intricate manipulations of special surgery. And for this the Anatomy Acts themselves, I believe, would require to be amended.

It does not seem to me, however, that any of those difficulties could not be got over, but their removal is going to entail more work and more time than is generally appreciated at the moment. And yet unti they are got rid of English post-graduate teaching wil be labouring under stress.

The most urgent need is for teachers, The clinica material in London is incomparable, but it is largel running to waste for want of teachers.

I am, Sir, yours faithfully,
DAN MCKENZIE.

Wimpole-street, Cavendish-square, W., Dec. 17th, 1919.

*** The developments of post-graduate facilities i London has been the object of very hard work b competent persons during the past year. Although ou correspondent is recalling much that is familiar t readers of medical journals, his exhortations will bea fruit if they lead to a larger support of the Fellowshi of Medicine.—ED. L.

THE DIETETICS OF GESTATION:
OR ANTENATAL DIETETICS.

To the Editor of THE LANCET.

SIR,—May I outline certain considerations and indications for further research which seem to arise from th recent work on "vitamines," as set forth in th invaluable new document published by the Medica Research Committee as Special Report No. 38? I would appear that the "growth" or "antirachitic factor is furnished to the milk of mammalian mother in their diet, if at all; and in its absence therefro rickets will ensue even in breast-fed infants, as notabl in those of the wrongly fed negresses of the Columbu Hill district of New York (loc. cit., p. 88). If th breast-fed infant is to thrive, the breast itself must b properly fed.

The Growth Factor in Gestation.

So much for lactation; but what of gestation? W cannot doubt that the growth factor is as necessary f embryo and fœtus as for the infant. This assurance corroborated by the observation that in fishes the growt factor is found in the roe, and that in birds it is foun in the eggs. The developing organism, piscine or avia is endowed and provided with this essential from th first. As for insects, we must study, in respect of vitamines, the two contrasted diets one of which produces a "worker" or sterile female bee, and the other a fertile "queen." We may expect to find a vitamine factor of gametogenesis. The mammalian embryo, however, must depend, in this newly discovered particular, as in all others, upon the maternal blood—at least after the very earliest stages of segmentation. Surely these considerations open a new chapter in what we may call, according as whether we look at the present or the future generation, either the dietetics of gestation or antenatal dietetics.

Dental Caries in Pregnancy.

Two well-known facts, hitherto obscure in causation, would seem now to be capable of explanation, if we proceed to experiment on the lines which it is the purpose of this communication to suggest.

The less important of these two facts is the dental caries so common in pregnancy. The work of Mrs. Mellanby on the development of the dental enamel in puppies' teeth,[1] according to the supply of the growth factor in their diet, suggests that the dental caries of pregnancy may be associated with the demands of the fœtus upon the growth factor which it requires from the maternal blood. Evidently the production of enamel and the protection of enamel are not the same process; but if the growth factor be the antirachitic factor, if it be protective in function, defect of it may cause defective production of enamel in the one case and defective protection of already formed enamel in the other. We know that thyroid deficiency produces different results in the developing and in the fully developed organism respectively. Further, defect of the growth factor in experimental rats and in children may cause xerophthalmia, due to lessened resistance to bacterial action; and the case of dental caries may be analogous. Should we not now make very exact and statistical observation, *in re* vitamine content, upon the dietaries of those pregnant women who respectively do and do not suffer from the acute dental caries of gestation?

Alcoholism a Cause of Still-births.

The more important of the two facts which now seem nearer elucidation is the large proportion of hitherto inexplicable still-births. We have lately learnt how many still-births are due to syphilis. In view especially of the experimental work of Stockard and Papanicolaou on guinea-pigs (work which I lately had the advantage of studying in detail at first-hand in New York) I suspect maternal alcoholism of frequently causing still-births in our species as in the experimentally alcoholised guinea-pig.[2] Sir R. Welsh Branthwaite, in many official reports, has given the reproductive history of chronic inebriate women in reformatories, showing a proportion of still-births, with tendency thereto *increasing* in successive years, unlike the sequence of syphilis. Dr. W. C. Sullivan, in a paper prepared for the National Birth-rate Commission, has noted the same increasing tendency to still-births in inebriate women. But, even if and when we make due allowance for this factor, there will remain a quite extraordinary proportion of unexplained still-births—32·6 per cent. in the well-known American series, and at least 25 per cent. according to Dr. Amand Routh in evidence recently given before the National Birth-rate Commission (the possible influence of alcohol not having been considered in either estimate). May not some at least of these deaths be due to antenatal "rickets" or deficiency disease consequent upon defective feeding of the mother?

Surely, these questions can and should be answered, clinically, pathologically by further microscopic study of dead-born fœtuses, and experimentally. But, even already one notable contra-indication for practice in the dietetics of gestation may be defined. Stout and porter, so long commended for motherhood, are signally condemned, first, as we knew, because they contain the toxic ingredient, alcohol; and, second, as we did not know, because they do not contain the essential vitamines. Malt and yeast are rich in these factors, but the process of brewing totally destroys them, beer, as we brew it, being thus the most common and nationally important example of a preserved, stale, artificial, devitalised because vitamine-deprived "food." Whether the alcohol or the high temperature involved in brewing destroys the vitamines—or dietary ferments, or trophozymes, as should we not call them?—is a subsidiary but not unimportant question.

Conclusion.

The conclusion is that we must make further experiment upon the dietary of gravid mammals. In 1906 I introduced the term "racial poison," now in general use, for such agents as lead and alcohol, which produce the germ-cell poisoning, or "blastophthoria" of Forel, or intoxicate the embryo or fœtus when ingested by the pregnant woman or other mammal. But it would now appear that we have to reckon with antenatal deficiency disease as well as with germinal or antenatal intoxication. My friend and teacher, Dr. J. W. Ballantyne, discussing the pathological condition of certain fœtuses, wrote as follows in 1902: "At the present time the cause of the dystrophy which has been described above is unknown. It may be guessed that the conditions which produce rickets in post-natal life are active in a modified form or in a different degree here."[3] I shall be honoured if he is able to attach any importance to my present suggestions for testing his views; and perhaps to amplify his pages on diet in his volume on "Expectant Motherhood," published as recently as 1914.

The recent experience of the Zoological Gardens in respect of pregnant animals under war restrictions of food may furnish some data worthy of correlation with future researches by the Antenatal Investigation Committee of the Medical Research Committee, and elsewhere on the lines here suggested; and the dietetics of expectant motherhood, hitherto exploited mainly by superstitions about beer and by quackery about the determination of sex, may attain a new and effective importance in the genesis of a healthy race.

I am, Sir, yours faithfully,

C. W. SALEEBY, M.D., F.Z.S., F.R.S.E.

Royal Institution, W., Dec. 20th, 1919.

Addendum, Dec. 30th.—May I add two notes? 1. At our own Zoological Gardens the view is suggested that the Polar bears, Sam and Barbara, failed to breed during the war, though they always bred before and have done so again this year, because of the deficiency of fat (? of "fat-soluble A") in their diet. 2. A Scottish correspondent tells me how its mother feeds the King Penguin chicken, the first ever raised in captivity, at the gardens of the Scottish Zoological Society: "The mother penguin lives entirely on fish and feeds its offspring by the regurgitation of the digested fish, and its transference from her own beak to the beak and down the throat of the chicken. The interesting point is that, up to the hatching of the egg, the mother accepted any kind of fish as food, but since she has had to feed her chicken she declines all fish except *herrings*. You will remember that herrings are specially rich in 'fat-soluble A.' Query: Does the mother penguin know more about vitamines than the human mother?" This query raises the profound question of the hazardous supersession of ready-made finite animal instinct by ignorant, teachable, infinite human intelligence; but the fact of natural history here recorded is fascinating.

---

UNIVERSITY OF PARIS: FACULTY OF MEDICINE.—A revision course on the nervous sequels of the war, touching on diagnosis, prognosis, and therapy, has been arranged by Professors M. A. Gilbert and M. Maurice Villaret at the medical clinic of the Hotel-Dieu from Monday, Jan. 26th to Saturday, Feb. 14th. Thirty-six practical demonstrations will be given by the professors and ten other lecturers. Foreign doctors will be admitted on application to the Secretariat of the Faculty.

Medical News.

UNIVERSITY OF EDINBURGH.—The annual report for 1918–19 records 1683 students in the Faculty of Medicine, 1310 men and 373 women, being an increase of 49 upon the number of women in the previous session. The nationality of these students is given as follows: Scotland, 948; England and Wales, 298; Ireland, 42; India, 53; Colonies, 296; Foreign, 46. The report shows that the following medical degrees were conferred: M.B., Ch.B., 95; M.D., 30; Ch.M. 1. Three new chairs in medicine have been founded: Chemistry in relation to medicine (Dr. George Barger), Therapeutics (Lieutenant-Colonel J. C. Meakins), and Psychiatry (Dr. G. M. Robertson). The chair in psychiatry was endowed by the managers of the Royal Edinburgh Asylum. A diploma in public health has been instituted. Sir Harold J. Styles has been appointed to succeed Professor F. M. Caird in the chair of clinical surgery, and Dr. F. M. Boyd to succeed Professor W. Russell in the Moncrieff Arnott chair of clinical medicine. Dr. D. Chalmers Watson and Dr. Edwin Bramwell have been appointed senior lecturers in clinical medicine, Mr. A. A. Scot Skirving, senior lecturer in clinical surgery, and Dr. D. Murray Lyon, lecturer in practical pathology. Of outgoing appointments, Dr. Harold Pringle has gone as professor of physiology to Trinity College, Dublin, and Dr. John Tait to the same position at McGill University. Grants and bequests during the year included an anonymous gift of £10,000 to endow a lectureship in orthopædics, and the Leslie gold medal in medicine.

At the graduation ceremonial held on Dec. 19th the following degrees were conferred:—

Doctor of Medicine.

Charles Edward Blair, Alexander Bremner, *William Francis Christie, Mary Olivia Fergusson, Joseph Geoghegan, David Alexander Ross Haddon, Sydney Herbert Hall, *Archer Hosking, Spencer Jackson, William Prideaux Selby Johnson, James Henry Kerr, Muriel Hamilton Kerr, Wilfrid M'Farlane, *William Keverall M'Intyre, Daniel M'Kelvey, *Robert Morison, William Tyrrell Patterson, *Kerr Simpson, and †Francis Hugh Stewart.

* Commended for thesis. † Highly commended for thesis.

Bachelor of Medicine and Bachelor of Surgery.

Ahmed Fahmi Abbassi, George Sandwith Bainbridge, Leonard van Renen Becker, Gladys Annie Adeline Boyd, James Godfrey Lyon Brown, Donald Arthur Cadman, Margaret Steele Caskie, Norman Henry Gustave Cloete, Alexander Younger Peattie Cochrane, Walter Hugh Critien, Dorothy Grace Davidson, Andrew Weir Davison (first-class honours), Herbert Joseph Alexander Dingwall, Henry Reginald Dodson, Norman M'Omish Dott, Evelyn Winifred Annie Dunderdale, Alexander Ralph Erskine, Millicent Fox, Gurdial Singh Gill, Alice Marian Graham, James Alphonsus Hennessy, William Augustine Hennessy, Ralph Allan Sarjeant Hoyte, Alexander Joe, Reginald Noel Johnson, Jacob Idzinga Kuit, John Learmont, Arnold Roland M'Lean, Jane Stewart M'Phail, William Malcolm MacPhail, Alexander Murray MacRae, Douglas Alexander Miller (second-class honours), Luiz Edmund Miller, Helen Morison, Georgina Isabella Blair Nichol, Emmanuel George Hamilton Payne, Donald Rankin, Edowo Awunor Renner, William Beattie Ross, Janet Craig Rugg, Muriel Sellers, Arnold Hoseason Shennan, Alexander Macdonald Simson, Shem Stein, Hugh William Young Taylor, Thomas Robert Rushton Todd, Vera Cecil Veitch, George Richard Simon Walles, David Tweedy Watt.

Diploma in Tropical Medicine and Hygiene.

Francis George Macnaughton.

UNIVERSITY OF ST. ANDREWS.—At recent examinations the following candidates were successful:—

Final Examination for Degrees of M.B., Ch.B.

Mildred Clark, Andrewina Laird, and Florence Braithwaite Mason.

Diploma in Dentistry.

Dental Anatomy.—Frederick Leonard Keith.

UNIVERSITY OF DUBLIN: TRINITY COLLEGE.—At examinations held recently the following candidates were successful:—

Final Medical Examination.

Part I., Materia Medica and Therapeutics, Medical Jurisprudence and Hygiene, Pathology.—Daniel de Bruijn, David John Browne, and Dorothy Alice Daly (passed on high marks), Philip Jabkovitz, Rev. Edward Gordon Campbell, James Carlisle Davis, Mary Horan, Frederik Wynand Pienaar, Frederick William Shegog, Patrick Ryan, Nora Griffith, Cecil Samuel Wilson, Robert Ruckley Baker, and Elinor Dorothy Stopford.

Materia Medica and Therapeutics, Medical Jurisprudence and Hygiene.—James Daly Leahy, William Allen Murphy, Robert Henry Joseph Mulhall Corbet, Anthony Divir Ward, George Septimus Moran, John Mervyn Semple, James Robertson Wills, Richard Wood Power, and Alfred John Beckett.

Pathology (in completion).—John Carson Brennan, Richard Victor Dowse, Henry Allman Lavelle, and Charles William Parr.

Part II., Midwifery (B.A.O.).—Eric Henry Cooke Allen and Olive Baile (passed on high marks), Wonter de Vos Scholtz, Essie Stuart Smyth, John Henry Brenell Crosbie and Johannes Philippus de Villiers (equal), William Bernard Joseph Pemberton, Salmon Louis Feldman and Joseph Ballantyne Maguire (equal), Edward Haslett Frazer, William Burton Fox, William Theodore Micks, Becher Fitzjames Haythornthwaite, Cecil Emrys McQuade, and Joseph Hirschmann.

Surgery (B.Ch.).—Leonard Abrahamson and John Gerard Holmes (passed on high marks), Thomas Donald Gordon, Charles John de Vere Shortt, Henry Allman Lavelle, Doris Louisa Graham, William Andrew Byrn and Richard Esmonde Murphy (equal), Jessie Gilbert, Johan Frederik Wicht, Maurice Nurock, Richard William Shaw, Arthur Isaac Steyn, Samuel John Laverty, Harris Cohen, and Athanas Blagoff.

Medicine (M.B.)—Leonard Abrahamson and Frederick William Robertson (passed on high marks), Francis Victor Small, John Gerard Holmes, Wonter de Vos Scholtz, William Joseph Hogan, Thomas Donald Gordon and Johan Frederik Wicht (equal), Henry Alfred Burridge, Joseph Hirschmann, Richard William Shaw, Richard Counihan, Moira Mary Brown, John Richard Waugh, William Andrew Byrn and Harris Cohen (equal), Charles John de Vere Shortt, Frederick W. Godbey, and Thomas Madill.

Diploma in Public Health.

Part I., Chemistry, Bacteriology, Physics, and Meteorology.—Victor Millington Synge, Robert Ernest Wright, Gerald Gordon Paul Beckett, Nicholas Hopkins Henry Haskins, George Francis Innes Harkness, William Henry Sutcliffe, John Stuart Dockrill, and George Oliver Fairtlough Alley.

Part II., Sanitary Engineering, Hygiene, Epidemiology, Vital Statistics, Public Health Law, Sanitary Inspection and Report.—Victor Millington Synge, Matthew McKnight, Robert Ernest Wright, Gerald Gordon Paul Beckett, Nicholas Hopkins Henry Haskins.

Diploma in Gynæcology and Obstetrics.

Roy William Chambers.

LONDON SCHOOL OF TROPICAL MEDICINE.—The following candidates passed the examination of this school at the termination of the autumn session:—

J. T. Duncan, W. G. Seymour, M. E. Barnes, C. C. Chesterman, E. C. Girling, M. Bequaert, R. Calleja, A. Kidd, E. S. Johnson, H. Lillie, G. F. Scuddar, W. Dawson, W. F. Hume, and G. M. Heydon (the foregoing passed with distinction); L. N. Lee, A. N. Bose, G. Chesney, R. Chalmers, J. H. Thomson, W. R. Young, E. C. Spaar, H. M. Pope, A. G. Fergus, J. Boodoosingh, P. F. Nunan, H. W. Webb, R. C. Briscoe, A. J. Galustian, T. D. Nair, P. W. Barnden, D. P. Jarjasingha, J. I. A. Sorensen, and N. Cheua.

UNIVERSITY OF LONDON.—A recent issue of the *London University Gazette* states that from the present time until a date to be fixed later by the Senate external students who have been debarred from presenting themselves for examinations for medical degrees by service under the War Office, or Admiralty, or by hospital service in connexion with the war, or by other approved service in connexion with national defence, will be: (1) permitted to enter at the First Examination for medical degrees in either (*a*) Inorganic Chemistry and Physics, or (*b*) General Biology, subject to the approval of the External Council; (2) credited with any subject in which they pass at the First Examination for medical degrees or Second Examination for medical degrees, Part II.; (3) permitted, if they fail in Forensic Medicine only in Group I. of the Third Examination for medical degrees, to present themselves for re-examination in that subject only in order to complete the examination in Group I., provided that they comply with the regulations in all other respects.

CENTRAL MIDWIVES BOARD.—A meeting of the Central Midwives Board was held at Queen Anne's Gate Buildings, Westminster, on Dec. 18th, 1919, with Sir Francis H. Champneys in the chair.—A letter was considered from Dr. R. P. Ranken Lyle, on behalf of the Newcastle Maternity Hospital, stating that owing to the great increase in the number of medical students in Newcastle and nurses at the maternity hospital, there is great difficulty in finding cases for all, and asking if the Board will consent to a case counting for a probationer midwife as well [illegible] for a medical student, and further stating that the medical officer of health for Newcastle would greatly approve of this concession being granted. The Board directed that Dr. Ranken Lyle be informed that the Board cannot see its way to the alteration which he suggests, as it would lower the standard of the training of midwives. The Board has no duties with regard to the training of medical students.—Letters were considered from the superintendent of the West Riding Nursing Association and the matron of the Ladies' Benevolent Institution, Chester, complaining of the treatment of candidates from those institutions who attended the Board's examination at Manchester in November last, and drawing attention to the views of the examiners at that centre with regard to the treatment of ante-partum hæmorrhage.—The Board also considered a letter on the same subject from the approved Teachers Subcommittee of the Midwives' Institute. The Board directed that every examiner be reminded that the correctness of any particular treatment cannot be determined by the private opinion of each examiner, but that the teaching of responsible authorities must be accepted.—A letter was considered from the secretary of the medical board of the Birmingham Maternity Hospital, again requesting the Board to receive a deputation from that hospital on the question of holding six examinations yearly at the Birmingham centre, and a further letter setting out the reasons for holding six examinations annually. The Board directed that the secretary communicate with the various approved institutions and midwives for their views on a scheme proposed by the Board.—A letter was considered from the secretary of the Central Midwives Board for Ireland suggesting an amendment of the form of having attended a course of lectures—Rule C.1 (1) (c) (Form IV. in Schedule to Rules)—with a view to allowing a course of 20 lectures to be delivered by more than one lecturer if necessary. The Board has always considered that it is best that the lectures should be delivered by one person. Its practice has been to accept the signature of more than one person in exceptional cases, and it has found this arrangement to work satisfactorily.

A special meeting of the Board was held on the same date, with Sir Francis Champneys in the chair. Three midwives were struck off the Roll, the following charges, amongst others, having been brought forward :—

> Being in attendance at a confinement, and the patient suffering from illness on or about the third day, the midwife did not explain that the case was one in which the attendance of a registered medical practitioner was required, as provided by Rule E. 20; she neglected to take and record the pulse and temperature of the patient at each visit, as required by Rule E. 14; the midwife did not on each occasion when attending the patient wear a clean dress of washable material, and over it a clean washable apron or overall, as required by Rule E. 2; and she neglected to wash the patient's external parts with soap and water, and to swab them with an efficient antiseptic solution, as required by Rule E. 8. Medical aid having been sought for a patient, the midwife neglected to notify the local supervising authority thereof as required by Rule E. 22 (1) (a). Being in attendance at a confinement and the child suffering from inflammation of and discharge from the eyes on or about the fourth day, the midwife did not explain that the case was one in which the attendance of a registered medical practitioner was required, as provided by Rule E. 21 (5). A midwife persistently neglected to notify the local supervising authority in cases where, pursuant to Rule E. 20, medical aid had been sought, in accordance with the provisions of Rule E. 22 (1) (a), and she did not on each occasion when attending her patients carry with her the appliances and antiseptics prescribed by Rule E. 3.

FEDERATION OF MEDICAL AND ALLIED SOCIETIES.—The regular monthly meeting of the executive committee of the Federation was held at 11, Chandos-street, W., on Dec. 30th, 1919, Sir Malcolm Morris in the chair. It was reported by the general secretary that the following medical Members of Parliament, in addition to those previously announced, had accepted seats on the council of the Federation: Captain W. E. Elliot and Dr. B. F. P. McDonald; so that out of the nine medical Members of Parliament (excluding Cabinet Ministers) six have now joined the Federation. The recent return of Lieutenant-Colonel F. E. Fremantle brings the number up to seven. The following additional societies have definitely joined since the last meeting of the committee: National Council for Combating Venereal Diseases, College of Nursing Limited, Association of Public Vaccinators of England and Wales, Medico-Psychological Association, Association of Panel Committees, Pharmaceutical Society of Great Britain, and British Science Guild. After full consideration by the executive committee of the Federation it was decided that the first step in giving effect to the resolutions of the conference held on Dec. 12th should be to approach the Minister of Health and endeavour to obtain his support on the broad principles adopted. Dr. Addison has, therefore, been asked to receive a deputation at an early date.

PROPOSED NEW HOSPITAL FOR LOWESTOFT.—From the medical report submitted to the annual meeting of the Lowestoft Hospital, Suffolk, on Dec. 16th, it appeared that during the year ending Oct. 31st, 1919, there had been 326 admissions of in-patients, 1184 out-patients, 1306 minor casualties, and 6690 attendances at the hospital under the War Pensions Scheme. The balance sheet showed an adverse balance for the year of £72 2*s.* 7*d.* in spite of a substantial increase of annual subscriptions. The cost per head per day for the maintenance of the patients and staff was 1*s.* 0¾*d.*, a moderate figure, which reflects credit on the administrative staff. A conference of medical men of the town and district was held recently, and a unanimous opinion was expressed that a new hospital on the block principle, built on a larger site, was essential in the interests of the town and district. Lowestoft is shortly to have a war memorial and the committee hope that the scheme will include an up-to-date hospital, worthy of those in whose memory it is to be erected, and adequate for the needs of the town and district it is intended to serve. The Red Cross Society has promised to give £8000, conditional on the money being applied towards the erection of a new hospital, and of the amount subscribed to the local War Memorial Fund £9500 has been earmarked for the proposed hospital.

AT a meeting of the Chester and North Wales Medical Society held on Dec. 19th, 1919, a resolution was unanimously passed that on and after Jan. 1st, 1920, the fees payable for medical examinations and reports in the case of life policies will be as under, viz :—For policies up to £100, 10*s.* 6*d.*; for policies over £100 and up to £200, 1 guinea; for policies over £200, 2 guineas.

THE VOLUNTARY HOSPITAL PRINCIPLE.—Speaking at the half-yearly meeting of the Yarmouth Hospital on Dec. 18th Dr. Raymond Shaw, the senior surgeon, said that the day had long gone by when the hospital could rightly be considered as a place for the treatment of poor patients only. Some modification of the system in the direction of admitting paying patients at the rate of one, two, or three guineas a week would have to be considered to meet the case of those unable to afford operations at home or at a private nursing establishment. This course was already adopted abroad and in the colonies, as well as in some London hospitals, and he foresaw its extension to provincial hospitals with advantage to everyone concerned.

ROYAL INSTITUTE OF PUBLIC HEALTH: CONGRESS IN BRUSSELS.—A letter has been sent to local authorities inviting them to appoint delegates to the forthcoming Brussels congress. The fee for each delegate is 1 guinea, which payment includes all the privileges of the congress, and on receipt of the names of the delegates appointed full information respecting the meeting (including travelling and hotel accommodation) will be sent to them. It is to be hoped that advantage will be taken of the opportunity to acquire knowledge of the public health administration of a country other than our own, more especially as the various government departments of Belgium have promised every support to secure the success of the meeting. The congress will be under the patronage of H.M. the King of the Belgians, and will be conducted in sections, each of which has both a Belgian and a British president. The sections comprise :—(1) State Medicine; (2) Naval, Military, Tropical, and Colonial; (3) Municipal Hygiene; (4) Industrial Hygiene: (5) Hygiene and Women's Work; (6) Bacteriology and Chemistry. The honorary secretaries of the congress are Professor Slosse, secretary to the Faculty of Medicine of the University of Brussels; Professor René Sand, secretary to the Academical Council attached to the Faculty of Medicine; Professor E. W. Hope, medical officer of health for the city of Liverpool; and Dr. T. N. Kelynack. The meetings will be held in the buildings of the University of Brussels, Leopold Park, from May 20th to May 24th, 1920.

AN IMPORTANT INSURANCE COMMITTEE DECISION.—An appeal recently undertaken by the London and Counties Medical Protection Society for one of its members against a decision of the East Sussex Insurance Committee raised a point of importance to panel practitioners. Under Article 21, Subsection 1, of the Medical Benefit Regulations an insured person desiring to select a practitioner is required to make application as the Committee, with the approval of the Commissioners, may require. In this case the manner of making application required by the Insurance Committee was set out thus:

> In any case in which an application from an insured person to be placed on the list of a practitioner, either by the presentation of a medical card or in such other manner as the Insurance Committee shall from time to time prescribe, is rejected by the practitioner, it shall be the duty of the practitioner (*a*) if the applicant is in urgent need of treatment to provide such treatment as the case may require, and (*b*) in every case to inquire whether the insured person wishes to apply to another practitioner on the panel or whether he wishes to apply to be assigned by the Committee to a practitioner on the panel.

In the case under consideration the insured person had caused to be posted an application to be placed upon the doctor's panel, which had, in fact, never come to his notice, and had consequently neither been accepted nor rejected by him. When the patient required medical attendance and sent for the doctor the application was then discovered for the first time by the doctor, who refused to attend on the ground that the patient was not in his area. The question arose as to whether the posting of the application by an insured person to a doctor constituted a "presentation" within the meaning of the article quoted. It was argued on behalf of the doctor that the word "present" in its natural and ordinary meaning meant a presentation in person, and that a construction which would enable applications to be made by post would not only place a serious additional burden of clerical work on insurance doctors, but would lead to a number of administrative difficulties.

After a lengthy discussion the Insurance Committee found in favour of the doctor on appeal, and agreed that the presentation of an application by an insured person to be placed upon a doctor's panel must be made either by the applicant in person or at least by an agent in the position to answer such inquiries as the doctor might require to put to him, as well as to convey such message relating to the application as the doctor might require to be sent to the applicant.

The Lord Mayor of London will act as chairman of the general committee promoting Health Week to be held from May 2nd to 8th next.

Viscount Astor will preside at the thirty-first Congress of the Royal Sanitary Institute, to be held at Birmingham from July 19th to 24th, 1920.

Dr. D. W. Carmalt Jones has been appointed Professor of Systematic Medicine in the University of Otago, and leaves for New Zealand early in February.

The London division of the National Deposit Friendly Society has endowed a cot in the Alexandra Ward of the Hospital for Sick Children, Great Ormond-street, at a cost of £1000.

The Public and Secondary Schools Red Cross Hospitals have handed over to the Village Centres Council (51, Lincoln's Inn-fields, London, W.C.) the balance of their funds, amounting to £3500.

The Executive Committee of the Fellowship of Medicine and Post-Graduate Medical Association called for to-day (Friday) has been postponed to Monday next (Jan. 5th), at 6 P.M., owing to the death of Sir William Osler, President of the Association.

St. Thomas's Hospital.—The old students' dinner, postponed from Oct. 1st, will take place at the Connaught Rooms, Great Queen-street, on Wednesday, Jan. 14th, at 7 for 7.30 P.M. The chair will be taken by Sir George H. Makins.

St. Mary's Hospital Medical School.—The annual dinner of past and present students, postponed from Oct. 1st, will take place at the Connaught Rooms, Great Queen-street, London, on Friday, Jan. 9th, at 7 for 7.30 P.M., Sir Almroth Wright presiding.

North-East London Post-graduate College.—The opening address of the spring session by Sir Humphry Rolleston on the Uses and Methods of Application of Post-graduate Teaching will be given on Tuesday, Jan. 13th, at 4.30 P.M., at the Prince of Wales's General Hospital, Tottenham, London, N. Medical practitioners wishing to attend will receive a card of invitation on applying to the Dean.

The Vermin Repression Society.—A dinner will be held at the Connaught Rooms, Great Queen-street, London, on Friday, Jan. 9th, at 7.30 P.M., to celebrate the passage into law of the Rats and Mice Bill, originated by the society in 1908. Lord Aberconway will preside, and he will be supported, amongst others, by Professor S. J. Hickson, Sir Anderson Critchett, Dr. W. J. Howarth, Dr. Nathan Raw, M.P., Professor W. J. Simpson, and Dr. J. W. Eyre. The society has recently issued a paper intended to be of service to all affected by the Rats and Mice (Destruction) Act, a copy of which will be sent gratis to any reader who sends a stamped, addressed envelope to the honorary secretary, Lieutenant Alfred E. Moore, 44, Bedford-row, London, W.C. 1.

Literary Intelligence.—Messrs. Longmans announce the publication at an early date of a volume on the Life and Work of Sir Jagadis Chandra Bose, the founder of the Bose Research Institute in Calcutta, and the first native of India to obtain a European reputation in physical science. The volume has been written by Professor Patrick Geddes, of the Department of Sociology and Civics, Bombay University.—Mr. Paul B. Hoeber, of 67–71, East 59th-street, New York, has issued for the Faculty of the College of Physicians and Surgeons of New York a portfolio of 24 portraits in photogravure of the medical staff of Columbia University, by Mrs. Doris U. Jaeger, at $10, with a preface by Dr. Samuel W. Lambert.

National Association for the Prevention of Infant Mortality.—A course of advanced lectures on infant care, for teachers, infant welfare workers, mothers, &c., will be held at Morley Hall, George-street, Hanover-square, London, W., on Mondays, from 5.30 to 6.30 P.M., from Jan. 12th to March 29th. This course is in preparation for the advanced certificate of the Association. Fees for the whole course of 12 lectures, 5s.—A course of advanced lectures on infant care, especially intended for creche nurses and probationers, will be held at the Essex Hall, Essex-street, London, W.C., on Thursdays, from 7.30 to 8.30 P.M., from Jan. 8th to March 25th. This course is in preparation for the creche nurses' certificate now instituted by the association in coöperation with the National Society of Day Nurseries. Fees for the whole course of 12 lectures, 10s. In both cases tickets can be obtained from Miss Halford, secretary, National Association for the Prevention of Infant Mortality, 4, Tavistock-square, London, W.C. 1.

New Year Honours.—A representative group of medical names appears in the list of distinctions published on Jan. 1st, 1920. To Sir Bertrand Dawson has fallen the honour, on which we comment elsewhere, of becoming the first practitioner peer. Knighthoods have been granted to Mr. Josiah Court, M.R.C.S., of Chesterfield, a magistrate and consulting surgeon to the Derbyshire Miners' Union; to Mr. Henry J. Gauvain, M.D., M.Ch., medical superintendent of Lord Mayor Treloar Cripples' Hospital at Alton; and to Mr. Frederick S. Lister, M.R.C.S., research bacteriologist to the South African Institute for Medical Research. Dr. W. T. F. Davies, a Member of the South African House of Assembly, receives the C.M.G. Three medical women receive the Kaisar-i-Hind Medal; Dr. Kate A. Platt, principal of the Lady Hardinge College at Delhi; Dr. Margaret I. Balfour, joint-secretary to the Lady Dufferin Fund; and Dr. Ida S. Scudder, in charge of Mary Taber Schell Hospital at Madras. Other recipients of honours, closely associated with the medical profession, are Sir W. E. Cain, a generous donor to Liverpool hospitals, who becomes a baronet; Mr. G. W. Needham, president of Oldham Royal Infirmary, and Mr. Thomas Neill, chairman of the Ministry of Health Consultative Council on Health Insurance, who become knights bachelor. Mr. Otto Beit's labours for the South African hospitals have been recognised by a K.C.M.G. Learning and exact science are honoured in the persons of Sir Richard Glazebrook, late director of the National Physical Laboratory, who becomes K.C.B.; and Professor Arthur Schuster, late secretary to the Royal Society, who has been knighted.

Liverpool Medical Institution.—At a meeting of the Pathological Section, held on Dec. 18th, 1919, with Dr. Hubert Armstrong, Vice-President, in the chair, Mr. Keith Monsarrat read a note on Two Cases of Massive Calculous Deposit in the Urinary Channels which had developed in soldiers while under treatment for fractures. Radiographs showed the development and retrogression of the calculi. The speaker was of the opinion that such cases did not belong to the domain of surgery, but could be cured by medical measures and exercise. Mr. G. P. Newbolt recounted a similar case where cure resulted after continuous treatment with citrate of potash. Professor E. E. Glynn contributed a paper on the Presence of Spirochætes in the Sputum of a Case of Bronchiectasis. The sputum was airless and purulent, but not nummulated, and contained round, yellow granules consisting of bacteria and spirochætes, the latter sometimes in enormous numbers. It seemed clear that these granules were formed not in the mouth but in the lung, and formed an airless medium wherein spirochætes could develop. It was suggested that they were a variety of Dittrich's plugs, which would probably be found to contain spirochætes if examined with that possibility in view. Graphs of the morphological features of these spirochætes, obtained by the measurement of large numbers of camera lucida drawings, were shown and compared with graphs of other spirochætes. They supported the suggestion that the condition was not the chronic stage of a previously acute bronchial spirochætosis, but was a secondary mouth infection. Professor Glynn was inclined to the view that the spirochætes in the granules were pathogenic, at least to the extent of increasing the severity of the disease. A similar condition had been found in a second case of bronchiectasis.

North of England Obstetrical and Gynæcological Society.—At a meeting held in Manchester on Dec. 19th, 1919, Dr. J. W. Bride read a paper on the After-results of the Removal of One or Both Appendages in Hysterectomy for Fibroids. The patients in 300 cases operated on at St. Mary's Hospital, Manchester, between the years 1909 to 1913 inclusive, for fibroids or, in a few instances, for chronic metritis, had been circularised. Dr. Bride based his paper on the 231 replies received. Questions were put bearing on general health, temperament, headaches, digestion, nervous stability, pain, capability for work, nutrition as regards fat, hot flushes, sexual inclination and comfort, and memory. Answers to the first six appeared in favour of the radical operation, but, with the possible exception of pain, the distinction was not very marked. The replies to the next four questions, particularly as regards flushings and sexual inclination and comfort, suggested the advantage of a conservative operation. The last question put produced indeterminate replies. In general there appeared to be very little to choose between the two operations. It was noticeable that flushings, both immediate and remote, were complained of in a number of cases where a conservative operation had been done. Dr. A. Donald, Dr. J. E. Gemmell, and Dr. W. E. Fothergill instanced objections to a conservative operation, the last-named observing that, as the ovary after hysterectomy ceased to function at the end of two years, it did not seem worth while to conserve it for that short period. He suggested as a sound rule for all operations involving removal either to leave a "working set" or to make a clean sweep.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

HERZFELD, GERTRUDE, M.B., Ch.B., has been appointed Assistant Surgeon to the Royal Hospital for Sick Children, Edinburgh.

JONES, D. W. CARMALT, M.D., F.R.C.P., to the Chair of Systematic Medicine in the University of Otago.

SMITH, A. W., M.D., temporary Assistant Physician, Crichton Royal Institution, Dumfries.

WILLIAMS, E. C., M.D. Lond., Medical Officer of Health by the Glamorgan County Council.

Royal Portsmouth, Portsea, and Gosport Hospital: WOODBURN, W. Y., M.D., Ch.B. Edin., Honorary Assistant Physician; CARLING, W., M.B., B.Ch. Camb., Honorary Assistant Anæsthetist.

Certifying Surgeons under the Factory and Workshop Acts: COSGROVE, E., L.K.Q.C.P., L.R.C.S. Irel. (Maynooth); GALLOWAY, W. H., M.R.C.S., L.R.C.P. Lond. (Otley); GILMORE, W., M.B., B.Ch., B.A.O. Belf. (Saintfield).

Vacancies.

For further information refer to the advertisement columns.

Ballinasloe District Asylum.—M.O. £225.

Birkenhead Borough Hospital.—Two Hon. Asst. M.O.'s.

Brighton, Royal Sussex County Hospital.—Hon. Surg. Clin. Asst.

Central London Throat and Ear Hospital, Gray's Inn-road, W.C.—Hon. Asst. Anæsth.

Charing Cross Hospital, W.C.—Orthop. S., Hon. Anæsth., and Three additional Hon. Anæsths.

Chester City and County.—Asst. M.O.H. £500.

Derby, Derbyshire Royal Infirmary.—Cas. O. £150.

Dorchester, Dorset County Council Education Committee.—School Dentists. £400.

East African Protectorates.—M.O.'s. £400–£20–£500.

Great Northern Central Hospital, Holloway, London, N.—H.S. £150. Two P.'s.

Huddersfield County Borough Education Authority.—Asst. Sch. M.O. £475.

Ilford Urban District Council.—Asst. M.O.H. £500.

Italian Hospital, Queen-square, W.C.—Hon. Anæsth. and Hon. Asst. Anæsth.

Lancaster, Royal Albert Institution for the Feeble-Minded.—Asst. M.O. £500.

Leasowe, Cheshire, Hospital for Children.—Jun. Res. M.O. £150.

Leicester Royal Infirmary.—Res. Anæsth. £300.

Liverpool, City Infectious Hospital, Fazakerley.—Asst. Res. M.O. £250.

Liverpool, Fazakerley Sanatorium for Tuberculosis.—Asst. Res. M.O. £300.

London Lock Hospital, 91, Dean-street, W.—Hon. S.

Lowestoft Borough.—Female M.O., &c. £500.

Manchester Children's Hospital, Gartside-street, Manchester.—Asst. M.O. £200.

Manchester Royal Infirmary.—Res. Anæsth. £100.

Metropolitan Asylums Board.—Sen. Asst. M.O. £450. Second Asst. M.O. £400. Third and Fourth Asst. M.O.'s. £350.

Middlesex County Council, Napsbury Mental Hospital, near St. Albans.—Jun. Asst. M.O. £400.

Middleton-in-Wharfedale Sanatorium, near Ilkley.—Asst. M.O. £450.

Ministry of Pensions Hospital, Orpington, Kent.—Res. Aural S. £400.

Neath Rural District Council.—M.O.H. £750.

Newcastle-upon-Tyne, Hospital for Sick Children.—Junior Res. M.O. £200. Hon. S. Also Hon. P. to Skin Dept.

Newport Education Committee.—Dent. £400.

Norwich, Norfolk and Norwich Hospital.—Cas. O. £200.

Nottingham City Asylum.—Second Asst. M.O. £350.

Nottingham General Hospital.—Cas. H.S. £150.

Plymouth Education Authority.—Asst. Sch. M.O. £400.

Queen Mary's Hospital for the East End, Stratford, E.—Hon. S.

Rainhill, near Liverpool, County Asylum.—Asst. M.O.'s. £300.

Reeth Union and Rural District Council, Yorkshire.—M.O.H., &c. £95.

Royal Free Hospital, Gray's Inn-road, W.C.—Surg. Regist. and Hon. Asst. Dent. Surg.

St. Helens County Borough.—Asst. M.O.H. £400.

Seamen's Hospital Society, Dreadnought Hospital, Greenwich.—S.

Seamen's Hospital Society, Hospital for Tropical Diseases, Endsleigh Gardens, N.W.—Med. Supt. £400.

Sheffield University.—Demonstrator in Path. and Bact.

Stafford, Staffordshire General Infirmary.—H.P. £200.

Stockport Infirmary.—Jun. Res. M.O. £200.

Straits Settlements.—Professor of Anatomy for Medical Department. $600 a month.

Sunderland Education Committee.—Female Asst. Sch. M.O. and Two Sch. Dent. £450 each.

Surrey, Virginia Water, Holloway Sanatorium (Hospital for the Insane).—Female Jun. Asst. M.O. £300.

University of Birmingham, Faculty of Medicine.—Lecturer in Bacteriology. £450.

Victoria Hospital for Children, Tite-street, Chelsea, S.W.—H.P. and H.S. Each £100.

Westminster Hospital, Broad Sanctuary, S.W.—P.

Whittingham County Asylum, Preston, Lancs.—Asst. M.O. £420.

Worcestershire County Council.—Asst. County M.O. £450.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Canterbury, Shanklin, Colnbrook, Dewsbury, Gamlingay, and Burnham Market.

Births, Marriages, and Deaths.

BIRTHS.

BESWICK.—At Elmwood House, Nantwich, on Dec. 24th, 1919, to Dr. and Mrs. W. T. Beswick (née Chandler)—a son.

CURNOCK.—On Dec. 26th, 1919, at a Nursing Home, the wife of D. Reginald Curnock, M.R.C.S., L.R.C.P., L.D.S. Eng., of a son.

DAVIS.—On Dec. 21st, 1919, at Upper Berkeley-street, W., the wife of K. J. Acton Davis, F.R.C.S., of a son.

DUN.—On Dec. 22nd, 1919, at Rodney-street, Liverpool, the wife of Robert Craig Dun, F.R.C.S. Eng., of a daughter.

FOX.—On Dec. 27th, 1919, at Ashburn-place, South Kensington, the wife of Reginald A. Fox, M.C., L.D.S., D.D.S., of a son.

HURRY.—On Dec. 25th, 1919, at "Ventnor," St. Matthew's-road, Worthing, the wife of Captain H. R. Hurry, R.A.M.C., of a daughter.

ILES.—On Dec. 26th, 1919, at Victoria-square, Clifton, Bristol, the wife of Arthur E. Iles, O.B.E., F.R.C.S., of a daughter.

LINDSEY.—On Dec. 20th, 1919, at "Beaumont," Portman-crescent, Bournemouth, the wife of Dr. Mark Lindsey, of a son.

MARRIAGES.

DUFF—LUMSDEN.—On Dec. 30th, 1919, at St. John's Church, Westminster, Mr. Donald Duff, F.R.C.S., Newton-place, Glasgow, to Margaret Simpson, only daughter of the late James Lumsden, Edinburgh.

LYNN-THOMAS—MACRAE.—On Dec. 9th, 1919, at St. George's U.F. Church, Edinburgh, by the Rev. Prof. H. F. MacKintosh, Charles Ivan Lynn-Thomas, formerly Lieutenant, 1st South Wales Borderers, son of Sir John Lynn-Thomas, K.B.E., C.B., C.M.G., and Lady Lynn-Thomas, R.R.C., of Greenlawn, Penylan, Cardiff, and Dorothy Guthrie MacRae, daughter of Duncan MacRae, of Ruthven, Kingussie.

SCOTT—WADDELL—On Dec. 26th, 1919, at Woodbank Hotel, Dumfries, Captain George Macdonald Scott, M.C., R.A.M.C. (S.R.), to Mia Mackintosh Gray, daughter of J. B. Waddell, Airlie, Dumfries.

DEATHS.

BRUNTON.—On Dec. 25th, 1919, at Rutland-gardens, Hove, Linton Brunton, M.R.C.S., aged 84.

BURGE.—On Dec. 25th, 1919, suddenly, Dr. Frederick John Burge (late of Shanghai), of Bournemouth.

JOHN.—On Dec. 27th, 1919, at Albion-road, Hampstead, William John, M.R.C.S. Eng., aged 78.

LISTER.—On Dec. 24th, 1919, at Bexhill, Charles Henry Lister, M.D., formerly of Croydon and Tunbridge Wells, aged 76.

LYLE.—On Dec. 30th, 1919, suddenly, at Speldhurst, Elmfield-road, Bromley, Kent, in her 48th year, Annie Seaton, the dearly loved wife of Herbert Willoughby Lyle, M.D. Lond., F.R.C.S., and only daughter of the late E. W. Winton, of Speldhurst, Tunbridge Wells, and of Mrs. Winton, of Etherton House, Widmore-road, Bromley. Funeral service at the Parish Church, Bromley, on Saturday, Jan. 3rd, at 11.15 A.M.

ROSS.—On Dec. 25th, 1919, at "Roslyn," 153, Brigstock-road, Thornton Heath, Surrey, William George Ross, M.D., formerly of the 8th (The King's) Regiment and Army Medical Department, aged 79. (15th May, 1840.)

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Communications, Letters, &c., to the Editor have been received from—

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Tuesday, Jan. 6th.

SURGERY: SUB-SECTION OF ORTHOPÆDICS (Hon. Secretaries—A. S. Blundell Bankart, R. C. Elmslie): at 5 P.M.

Cases:

Mr. Laming Evans: Osteitis of Tibia of Doubtful Nature.

Mr. R. C. Elmslie: Traumatic Coxa Vara in a Child aged 8 Months, due to a Birth Injury.

Wednesday, Jan. 7th.

SURGERY: SUB-SECTION OF PROCTOLOGY (Hon. Secretaries—W. Sampson Handley, Sir Gordon Watson): at 5.30 P.M.

Discussion:

On "Diverticulitis," to be opened by Dr. Maxwell Telling. The Discussion will be continued by Professor A. Keith, Mr. Lockhart-Mummery, Dr. E. I. Spriggs, Mr. McAdam Eccles, Mr. Grey Turner, Mr. Rutherford Morison, Mr. Hamilton Drummond, Mr. Garnett Wright, Mr. James Berry, Mr. R. P. Rowlands, Mr. Maynard Smith, Mr. H. S. Clogg, Mr. A. C. Jordan, Mr. Ivor Back, Mr. Peter Daniel, Mr. L. E. C. Norbury, Mr. W. E. Miles, Dr. de Bec Turtle, Sir C. Gordon Watson, Mr. Hernaman-Johnson, Mr. Sampson Handley.

A collection of specimens illustrating the subject of discussion will be on view from 2.30 P.M.

If necessary the Discussion will be adjourned and be reopened by the President of the Sub-Section, Mr. Lockhart-Mummery.

Following the meeting on Jan. 7th the Annual Dinner of the Sub-Section will be held at Oddenino's Restaurant, 60, Regent-street, at 8 for 8.15 P.M. Cost of dinner 13*s.* 6*d.*, exclusive of wine. Members of the Sub-Section are entitled to invite one guest, but must intimate their intention to Mr. Sampson Handley before Jan. 3rd.

Thursday, Jan. 8th.

NEUROLOGY (Hon. Secretaries—P. W. Saunders, George Riddoch): at 8.30 P.M.

Paper:

Dr. F. M. R. Walshe: Forms of Peripheral Neuritis among Troops serving with the Egyptian Expeditionary Force 1915–1919.

Friday, Jan. 9th.

CLINICAL (Hon. Secretaries—T. P. Legg, S. A. K. Wilson): at 5.30 P.M.

Address by the President:

Sir Anthony Bowlby: The Application of War Methods to Civil Practice.

Exhibition of Cases.

Will any members of the Section who desire to show cases please communicate with the Hon. Secretaries?

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

LONDON HOSPITAL MEDICAL COLLEGE (UNIVERSITY OF LONDON), Mile End, E.

A Course of Instruction on the Diseases of Children, open to Post-Graduates and to Students of the Hospital. (The lectures will be illustrated by lantern slides.)

SATURDAY, Jan. 10th.—10.15 A.M., Dr. Hutchison: General Diseases. (At the Anatomical Theatre.)

ROYAL INSTITUTION OF GREAT BRITAIN, Albemarle-street, Piccadilly, W.

Christmas Lectures on the World of Sound, by Prof. W. H. Bragg, C.B.E.:—

TUESDAY, Jan. 6th.—3 P.M., Lecture IV.:—Sounds of the Town.
THURSDAY.—3 P.M., Lecture V.:—Sounds of the Sea.
SATURDAY.—3 P.M., Lecture VI.:—Sound in War.

BOOKS, ETC., RECEIVED.

FROWDE, H., AND HODDER AND STOUGHTON.
The Cambridge Note Book for Practical Biology (Zoology). By J. S. Gardiner, F.R.S., and L. A. Borradaile, M.A. 5*s.*
A Guide to Gynæcology in General Practice. By Comyns Berkeley, M.D., M.C., and Victor Bonney, M.S., M.D. Pp. 467. 31*s.* 6*d.*
The Microscopic Anatomy of the Teeth. By J. Howard Mummery, D.Sc., L.D.S. Pp. 382. 25*s.*

LANE, JOHN, London and New York.
The End of a Dream. By A. M. N. Jenkin. Pp. 292. 7*s.*
The Margaret Book. By A. Clark, N.Z.M.C. Pp. 189. 5*s.*

LAURIE, T. WERNER, London.
The Truth of Spiritualism. By "Rita" (Mrs. Desmond Humphreys). Pp. 152.
Madame Prune. By Pierre Loti. Translated from the French by S. R. C. Plimsoll. Pp. 240. 10*s.* 6*d.*
Why we do it: Pathological Gossip. By R. McMillan. Pp. 218. 6*s.*

LEA AND FEBIGER, Philadelphia and New York.
Pulmonary Tuberculosis. By M. Fishberg, M.D. 2nd ed. Pp. 744.
Roentgen Interpretation. By G. W. Holmes, M.D., and H. E. Ruggles. Pp. 212. $2.5.
The Principles of Nursing. By C. A. Brown, R.N. Pp. 262.
A Manual of Hygiene and Sanitation. By S. Egbert, M.D. 7th ed. Pp. 554.
Rules for Recovery from Pulmonary Tuberculosis: A Layman's Handbook of Treatment. By L. Brown, M.D. 3rd ed. Pp. 192.
Applied Anatomy and Kinesiology. By W. P. Bowen, M.S. 2nd ed. Pp. 334.
Experimental Pharmacology. By H. McGuigan, M.D. Pp. 250.
Hygiene and Public Health. By G. M. Price. 2nd ed. Pp. 280.

Notes, Short Comments, and Answers to Correspondents.

CHRONIC DISEASE AND CIVIC INEFFICIENCY

Being Part of a Chadwick Lecture on "The Relation of the State to Chronic Disease."

BY R. O. MOON, M.D. OXON., F.R.C.P. LOND.,
CONSULTING PHYSICIAN, WESTERN GENERAL DISPENSARY, MARYLEBONE, ETC.

How is the State to deal with the civic inefficiency which results from the partial disablement caused by chronic disease? Speaking generally, most patients with any kind of chronic disease who are able to be up and about are really the better for some occupation; the occupation, in fact, may be regarded as a part of the treatment. Unfortunately, men who suffer from chronic disease are seldom able to earn a full day's wage; cases of tuberculosis, which are otherwise fairly well, cannot as a rule work for more than 5–6 hours per diem, and on economic grounds it would be justifiable to subsidise the labour of consumptives.

In regard to epileptics—I am not speaking of those who have fits with great frequency or in whom there may be indications of mental alienation—the average case that comes to the out-patient department of a hospital can, from the point of view of physical strength, work at most ordinary occupations with some safeguarding. Obviously there are activities for which epileptics are ineligible; thus a large part of the building trade would have to be ruled out, and any occupation in close contact with machinery. There remain a number of employments in which an epileptic can do the work of an A 1 man.

Many other diseases of the nervous system, both those technically known as "functional" as well as those in which some organic lesion of the spinal cord is present, are far from being incompatible with wage-earning occupation if careful study were made of the kind of activity suited to each affection.

As regards the sum-total of loss of labour, pain, and general suffering, diseases connected with the heart probably exceed tuberculosis in importance; but for heart disease there are no after-care committees. Cardio-vascular disease should, like tuberculosis, be attacked at its source. The most important single cause of heart disease is rheumatism, and could we abolish this in early life 50 per cent. of circulatory troubles would disappear. Rheumatism should be easier for the State to deal with than tuberculosis, since we are not troubled with the question of infectivity; on the other hand, we have more precise knowledge of tuberculosis than of rheumatism.

Industrial Strain.

Apart from rheumatism, the dominant cause of circulatory breakdown is the strain of industrial conditions. Work which a man of 20 finds well within the range of his powers may be exhausting when he reaches the age of 50. Some occupations involve periodical rushes, and are unfitted for most men past middle life. The ætiological importance of industry as a factor in disease has hardly been sufficiently appreciated. Each succeeding stage of industrial development has been attended by labour problems, social difficulties, and manifestations of ill-health peculiarly its own.

At the present day there are special types of fatigue due (1) to the intensive nature of the work; (2) to its monotony; (3) to strain. There are a number of hours during which a man can work comfortably, and beyond these labour loses its productive value. Obviously, all occupations are not equally fatiguing for the same number of hours worked, consequently the number of hours of work must differ considerably in different trades, and to fix the same length of working day for all trades would be highly irrational.

It ought to be possible to draw up a list of chronic diseases with the kinds of activities for which they are suited. In this the State should work hand in hand with the medical profession, by thinking over the various industrial and agricultural occupations, collating the growing medical experience thereon, in order to determine what activities are favourable to what diseases. Something of this kind has been done in connexion with disabled soldiers, but it might be extended to all citizens. Thus the employment bureau of the labour exchanges has furnished a very useful list of occupations suitable for various forms of inactivity, e.g., occupations suitable for those who have lost one arm have been found to be: (1) Substation switchboard; (2) wholesale tailoring; (3) hand-loom weaving; (4) french polishing; (5) draughtmanship; (6) surveying; (7) commercial work; (8) book-keeping; (9) commercial traveller; (10) forestry and certain forms of agricultural work; (11)

lephone exchange operator; (12) diamond cutting (only per cent. of wages can be earned by them at this).

In numerous cases a man working before the war at an nskilled trade for which his disability unfits him, has been ained in a Government school for [illegible] skilled occupation; any inborn talents thus have the opportunity of displaying emselves.

Varieties of Light Occupation.

One advantage of a civilisation with its highly developed vision of labour is that it makes it more possible to find ccupation for the permanently disabled owing to the eater variety of "light jobs." In a purely agricultural mmunity the outlook would be far less favourable, as there e but few departments of agricultural work where the bour can be considered as really light. Speaking generally, e occupations connected with agriculture are specially ited for those who are suffering from shell shock, neurasenia, or tuberculosis. Connected with agriculture, though bsidiary to it, are horticulture, fruit-growing, and estate rpentry, all of which may be suitable for those requiring tdoor employment but unable to do heavy work.

What occupations can be indulged in safely and with profit y those suffering from heart affection? Most doctors have et with men who, in spite of a serious disease of their heart, ave been able to do astonishingly hard work, but such ses are exceptional. "Basket-making," which is naturally assed [illegible] "light work," sometimes proves unsuitable for ose suffering from a comparatively minor affection of the eart; the making of a large basket involves [illegible] wide tension of the arms and an undue strain upon the eart. A discharged soldier with a not very serious ndition of his heart, found himself unable to do ot repairing because it involved standing upright at the ench for long hours at a stretch, which, of course, uts [illegible] strain upon the circulation. Boot-making, though assed [illegible] "light occupation," is not suitable for ost forms of heart disease as it involves much use of the ms both in hammering and wide stitching; the posture boot-makers is also bad for all kinds of chest complaints. ut many kinds of light leather work are eminently suitable r such ailments, and the fine stitching required in the boot ade has proved particularly suitable for some forms of eurasthenia. It has been stated by Sir James Barrett that e unemployed of the better class are those who have ever been taught to do anything properly. If every ember of the community received an adequate training r some special occupation the increased value of their bour would abolish poverty and solve the social problem.

COLONIAL HEALTH REPORTS.

St. Helena.—The estimated civil population on Dec. 31st, 18 was 3654. The death-rate in 1918 among civilians was 85 per 1000, the lowest since 1909. The birth-rate was 30·65 r 1000, the highest for the last 10 years. Of the 36 deaths gistered, [illegible] were over 70, 3 over 80, and 1 of 92 years of age. here were 37 marriages, as against 33 in 1917. The Acting olonial Surgeon reports a slow but steady decline in the neral health of the colony, as evidenced by mild epidemics influenza, dysentery, and chicken-pox. Cases of phthisis d tuberculosis were rare. Dental caries is very prevalent d runs riot, as there is no dentist in the colony; it is very rgely responsible for the low stamina of the inhabitants d their inability to resist minor diseases. The island has en fortunate in entirely escaping the so-called Spanish fluenza. The mean temperature was 61·4° F. and the total infall 40·13 inches (9·30 inches less than in 1917). There ere 164 admissions to the hospital during the year and ere were 8 deaths. The nursing staff was under strength r the greater part of the year, and much extra work and sponsibility fell on the shoulders of the superintendent, iss Hart.

Fiji.—According to a report by the acting Colonial ecretary (Mr. R. Rankine) on the Blue-book for 1918 the timated population on Dec. 31st, 1918, consisted of 4748 uropeans, 2803 half castes, 61,745 Indians, 2709 Polynesians, ,761 Fijians, 2100 Rotumans, 913 Chinese, and 637 others—tal 163,416, as compared with 139,541 at the Census of 1911. [illegible] compared, however, with 1917 there was a decrease of 75. The outstanding event of the year, fraught with rious consequence to the colony, was an outbreak of fluenza in November. The epidemic came at a time hen, owing to the depletion of the medical service, cal shipping difficulties, and the dislocation of steamer rvices with Australia and New Zealand in conquence of labour troubles, the task of coping with it was ore difficult than would have been the case in normal mes. So soon as the epidemic assumed a serious nature e services of practically the whole European population ere placed unreservedly at the disposal of the Government, d voluntary workers assisted in attending not only uropeans, but also Fijians, Indians, and other coloured embers of the community. Temporary hospitals were tablished in Suva and other centres, and hospitals belonging to plantation owners were requisitioned and used for the treatment of patients. Medical relief parties from New Zealand and Australia, under Colonel Jennings and Major Alexander respectively, rendered excellent assistance in various parts of the colony. The local medical officers worked at exceedingly high pressure throughout the epidemic, and their services and those of the medical relief parties and voluntary workers undoubtedly saved a very large number of lives. Notwithstanding the steps taken, the epidemic caused deaths numbering 8145, being 4·96 of the population, while the expenditure incurred amounted to some £10,000. The Colonial Hospital, Suva, is the principal medical institution in the colony. The number of patients treated in 1918 was 2480, of whom 266 were Europeans. There is a branch hospital at Levuka; admissions during 1918 were 534. There are 11 provincial hospitals for the treatment of native Fijians, and to these the admissions totalled 6324. Government medical officers attached to several of the hospitals were absent during the year on war service, and in those cases native medical practitioners were left in charge. A leper asylum on the island of Makogai is under the charge of a medical superintendent, who is assisted by [illegible] European medical officer and five European and three Fijian nursing sisters. The lepers in the asylum on Dec. 31st, 1918, numbered 327.

Seychelles.—The estimated population of the colony at the close of the year 1917 was 24,572. The birth-rate for the year was 26·13 per 1000, the proportion of illegitimate children being high; the death-rate was 17·4 per 1000. In the Victoria Hospital 748 in-patients were treated, and in the Government dispensaries 3583 patients were treated. The Maternity Home continued to be well patronised, the number of patients admitted being 207, and the number of babies born 151. The average number of patients in the Lunatic Asylum, South Mahé, during the year was 23. An epidemic of measles which started in December, 1917, continued for the first six months of 1918. The schools were kept closed during January, February, and March. Nearly all the children under 15 years of age contracted the disease, which was for the most part of a mild type, and complications were singularly few. There were no other epidemic diseases during the year, and the general health of the inhabitants was good. The prevailing poverty made itself felt on health to a small extent, the sufferers being mostly very young children. The ankylostomiasis campaign was continued with unabated vigour by Dr. J. F. Kendrick of the International Health Board. By the end of the year the campaign had been completed over the whole of the Mahé, to the great benefit of the general health.

DEA PALLIDA.

O! Lady of the twisted smile and doubtful glance,
  Creeping with hungry lip and darting eye
Throughout the world! Men worship you in France;
  On Thracian hills, through Spain and Italy
They tend your fires; the misty, northern isle
  Is careful of your rites; far sun-rise lands
Are ancient slaves to you; exulting Nisle
  Has caught you to his breast; the desert sands
Are burned with your desire; each Holy Place
  Has pushed aside the veil (Jerusalem
Or Mecca—where you will), and [illegible] your face,
  And pays the growing price. Your diadem,
Jewelled with tortured souls, is fair to see,
  And where you nod men follow steadfastly.

S. K. VINES.

FATAL BLOOD-POISONING IN NORFOLK.

Two fatal cases of so-called blood-poisoning have been recently reported in Norfolk. The first case occurred at Yarmouth. The patient sustained a slight wound, little more than a scratch, on the first finger of her left hand while cutting up some foreign bacon on Dec. 12th. Next day she complained of some pain in her chest and sent for a doctor, who considered at first that she was suffering from a form of acute rheumatism of the muscles of the chest wall. There had been a shivering attack the previous night, but there [illegible] no sign of inflammation either in the cut finger or the arm. A consultant's opinion was obtained from Norwich, and the medical men agreed that there was no cause in the lungs to account for the symptoms, but that the patient was suffering from septicæmia, which had originated from the wound in the finger, but had passed the usual barriers in the forearm and axilla and directly affected the general circulation. The patient died a few days later from acute septicæmia.

The second case was that of a middle-aged man who [illegible] a splinter of wood under one of his finger-nails. He consulted his panel doctor, who, finding the hand acutely inflamed and the man apparently very ill, told him he must go into hospital, as an operation would be necessary. The man accordingly walked to the Norfolk and Norwich Hospital, a distance of about five miles, when two operations were performed, in spite of which he died from acute septicæmia.

METHYL ALCOHOL AND BLINDNESS.

THE tragedy reported from New York, in which a hundred or more persons lost their lives and many others their sight from drinking wood spirit, apparently in mistake for whisky, calls public attention to the exceedingly poisonous character of methyl alcohol. So long as wood spirit was a dark, evil-smelling liquid few were tempted to take it as a beverage, but as now purified it is scarcely distinguishable to the eye or to the nose from ethyl alcohol, and probably provides an agreeable diversion to the jaded palate. The danger has been foreseen for some time, and the National Committee for the Prevention of Blindness (130, East Twenty-second Street, New York) issued broadcast the following warning: "One teaspoonful of wood alcohol taken internally is sufficient to cause total blindness—a larger quantity often causes death. If you value your eyesight or your life, never use wood alcohol, denatured alcohol or medicated alcohol for drinking purposes. Pass this knowledge on if you would assist in reducing the fatalities which are occurring from this cause." The tragedy will not be all loss if it serves as an effectual reminder that any substitute for alcohol can only be taken at deadly personal risk.

PROPOSED NEW WELSH HOSPITAL.

Mr. H. Seymour Berry, J.P., of Merthyr, has offered to provide a site at Pontsarn, near Merthyr Tydvil, and spend £10,000 on temporary hospital buildings. He is also willing to give £10,000 towards the provision of a new permanent general hospital on condition that the public establish an endowment fund of £100,000.

A WAISTCOAT POCKET CALENDAR.

THE R. H. Heward Company, Twickenham, have published a convenient little calendar for the waistcoat pocket. It measures 2 inches by 1½, has a leather cover, and in addition to an almanack in bold type gives the dates of bank holidays, movable feasts, and postal information. The company state that they are willing to send one of these useful calendars to anyone who is interested in surgical instruments and appliances.

GERMAN HOUSING STRAITS AND SCHEMES.

THE Ministry of Health has issued a report prepared by what was once the Intelligence Department of the Local Government Board on the housing problem in Germany.[1] There matters have followed generally much the same course as in this country, but owing chiefly to the rapid growth of the German population in recent years, the shortage is even more acute than in Great Britain. The investigations undertaken by the Berlin District Sickness Society disclosed in many cases an appalling state of things. In 1917, for example, two-thirds of the persons visited were living in rooms with no through ventilation, and in a few cases the rooms had no windows; in 36 per cent. of the households an insufficiency of beds was reported. The report goes on to describe the methods that have been adopted so far in Germany to deal with these difficulties, and commends particularly the close attention which has been paid to the subject of town planning. The report is brought up to date by the inclusion of the most recent orders and proposals whose success or failure have yet to be demonstrated.

REDUCTION IN VAGRANCY IN WEST SUSSEX.

THE annual report of the West Sussex Casual Pauper Committee provides some remarkable figures. The principal feature of the operations of the committee is the issue of food tickets in order that the casual paupers may have no excuse for begging, and that this system has met with extraordinary success is shown by the figures just issued in the thirteenth annual report of the committee. Before the system of the committee came into operation no fewer than 19,599 casual paupers were relieved in 12 months (1906) in the county of West Sussex. The figure for the year just ended was 1729. The following shows the figures for each year since 1906, the year 1907 being the first year of the system's operation:—1907, 16,760; 1908, 15,579; 1909, 15,231; 1910, 12,575; 1911, 11,679; 1912, 11,967; 1913, 9109; 1914, 8285; 1915, 581[illegible]; 1916, 4095; 1917, 3422; 1918, 3428; 1919, 1729. It is evident that the operation of this system has brought about a rude change in the life of the habitual tramp, at least in the western half of the county of Sussex. It would be interesting to know what is the experience of other parts of the country—whether the elimination from West Sussex of these dangerous nomads has caused an unusual influx elsewhere. However, the work of the West Sussex committee is not to stop here. It is recorded in its report that the Inter-Counties Vagrancy Committee has determined upon the following: (1) The advisability of the establishment of labour colonies for vagrants; (2) appointment of an executive committee to carry out the resolutions of the committee; (3) the dealing with the discharged sailors an soldiers, on their applying for admission to the casual wards on the lines passed by the committee; and (4) compilation o statistics of arrangements in connexion with the control o vagrancy made by the various vagrancy committees. Th West Sussex committee is to be congratulated on the succes of its labours in reducing in number a body whos picturesqueness has disappeared, and who must be a menac to the countryside.

WINDOW FATALITIES.

To the Editor of THE LANCET.

SIR,—An article entitled "Fatalities in Hospitals Cause by Patients Falling from Windows" (*Journal of the America Medical Association*, August 23rd, 1919, p. 604) tempts me t describe a scheme we have used in the More Hospital for number of years to lessen the opportunities for deliriou patients to escape from the hospital.

We installed a special enunciator in the main hall nea the general service one. This special enunciator has loud bell, differing in tone from the other. From thi enunciator concealed wires extend to a small copper-plat in the baseboard near a corner in each room and ward. I a patient becomes delirious his bed is rolled into the corne of the room or ward, and an electric mat, about 3 ft. by 5 ft in size, is placed in front of the bed and connected by wire to the copper-plate in the baseboard. Over this is place a common rug. Any pressure, as a nurse or patien stepping on the rug, causes the bell attached to the specia enunciator to ring, and is a warning to the nurses.

In a small hospital, especially, all nurses can be readil informed that there is a delirious patient in a certain room and at the sound of the bell it is seldom necessary to go firs to the enunciator to see where the call comes from. Ou experience has been that the nurses are alert and respon promptly to this emergency call. I, myself, have been o the floor when the bell sounded, and have seen two or thre nurses meet at the patient's bedside before he had time t leave the room. No delirious patients have escaped from th hospital or been injured.

I am, Sir, yours faithfully,
C. W. MORE, M.D.
Eveleth, Minn.

CONVERTING GRAMMES INTO OUNCES.

To the Editor of THE LANCET.

SIR,—Following on my letter in THE LANCET of Oct. 25th giving the formula and a mnemonic for converting ounce into grammes, I have been asked for a mnemonic for th formula for the reverse process—namely, grammes int ounces. The formula is, of course, multiply the gramme by ·03527. My mnemonic is "By five fairy figures ranged Stop o Gramme for ounce be changed." (It might b entitled "The Fairy Change.") The "Stop o" recalls th decimal point and zero; and, counting the number of letter in the words "for ounce be changed," gives the sequenc 3·5·2·7. Apart from this, the easily remembered figures 56 grammes equal almost exactly 20 ounces avoirdupois, an thence other proportions can be derived. I have never see this mentioned anywhere. Also, for rough-and-read purposes, if one thought of 456 grammes equalling a poun it would afford a useful clue, as it is easily remembered an easily divisible into 228, 114, 57, 28½, 14¼, 7⅛—that is, down t a quarter of an ounce; and fine adjustments, if desired, ca be made by the first-mentioned formulæ.

I am, Sir, yours faithfully,
F.
London, Dec. 19th, 1919.

A FAVOURABLE SEQUEL TO THE INFLUENZA EPIDEMIC IN AMERICA.

THE industrial mortality records of the Metropolitan Li Insurance Company of New York City show that the healt conditions during last autumn were the most favourable f years past. There were no signs of a recurrence of influenz and the mortality from other diseases was at an unusual low point. Doubtless a large number of susceptible perso were carried off prematurely by the epidemic who wou probably have died this year. At all events, no serio aftermath of the influenza epidemic of 1918 has yet appeare The low death-rates among its policy-holders for the mont of July, August, and September were followed by astonis ingly favourable developments during October a November. Instead of the marked increase that expected in these months, as compared with the summ months, the mortality in October was only very slightly excess of that for September, and was much lower than t normal. Instead of the increase which is usually shown f November, the rate actually declined over 8 per cent. fro the figures for October. A decrease of 16 per cent. in t death-rate for tuberculosis was recorded for November.

Pleximeter is entitled to claim abatement in his income-t return in regard of the cost of tyres, petrol, repairs, a renewals for a car kept for professional purposes, as well the wages and board of the chauffeur.

Bradshaw Lecture

ON

THE SURGERY OF THE HEART.

Delivered before the Royal College of Surgeons of England on Dec. 11th, 1919,

BY SIR CHARLES BALLANCE, K.C.M.G., C.B., M.V.O., M.S. LOND., F.R.C.S. ENG.,
CONSULTING SURGEON TO ST. THOMAS'S HOSPITAL, ETC.

(Continued from p. 5.)

II.—THE SURGERY OF THE HEART.

THE operations now practised on the heart are: 1. Paracentesis—pericardiotomy. 2. Paracentesis of the right auricle and ventricle. 3. Operation for air embolism of the heart. 4. Cardiac stimulation for arrest of the movement of the heart. 5. Cardiolysis. 6. Operation for injury of the heart itself. Cardiorrhaphy.

1. PARACENTESIS AND PERICARDIOTOMY.

Paracentesis pericardii was first advocated by Riolanus (1649) and trephining the sternum (Riolan's method) was done by Skielderup (1818) and by Malle (1871); but such a severe operation is altogether unnecessary. Trousseau established the method of open incision in France, though Dieulafoy advocated aspiration. Clifford Allbutt (1866), a pupil of Trousseau, persuaded Wheelhouse to tap a pericardium much distended in the course of an attack of rheumatic fever. The patient was dying, and Clifford Allbutt got Wheelhouse out of bed to do the operation.[1] Recovery ensued. This was the first case of the kind in England, and the news of it was quickly followed by the publication of similar cases by Bowditch of the United States, Roberts of Manchester, and many others.

The operation of paracentesis pericardii, or aspiration of the pericardium, should be, I think, banished from surgical practice; just as puncture of the distended abdomen is no longer done in cases of obstruction. It is a leap in the dark, and many cases of wound of the heart or coronary artery have occurred in the course of this operation.[2] Free and safe exposure of the pericardium can be obtained by removing the sternal ends of the left sixth and seventh cartilages. The internal mammary artery must be drawn aside or tied and the triangularis sterni divided. The pulp of the surgeon's finger must be able to examine the pericardium before an incision is made. The knife should be employed to open the pericardial sac. The abundant literature that has accumulated, and the diversity of opinion as to the best site for puncture is of itself evidence that paracentesis is neither simple nor safe.

Trousseau graphically describes the signs and symptoms of gradual distension of the pericardium with fluid. The following is a paraphrase:—

> There is great oppression of the breathing and the facial anxiety increases from day to day. The pericardial dullness soon covers a wide area. It extends from beyond the right edge of the sternum to 3 or 4 cm. outside the nipple line and in the vertical direction from the third rib to the diaphragm. The precordial region is arched. The pulsations of the heart become obscure and muffled as if distant, and finally cease to be heard. The pulse is small and rapid. At the end of a few weeks the dyspnœa is extreme, the patient cannot lie down, the lips are blue, the skin cold and livid, the extremities œdematous, and the face puffy. There is no albuminuria.

Pericardiotomy.

A limited pericardiotomy is the operation of choice for hydrops. A point to remember is that the operator may not know in some cases before incising the pericardium whether the fluid within is serous, bloody, or purulent. Voinitch[3] recommends the resection of the left sixth and seventh cartilages and the adjoining edge of the sternum, thus opening up the costo-xiphoid angle and the costo-sternal interval in the diaphragm. The exposure seems unnecessarily wide for the relief of hydrops, but the point to emphasise is that the lower the opening in the pericardium the better the drainage. I agree with Matas that the lower the point selected for drainage the less likelihood is there of danger to the pleura and heart, and that it is well to strike the pericardial effusion where it is largest and most dependent. The danger of wounding the pleura in pericardiotomy is non-existent with moderate skill on the part of the operator. The idea is a relic of a bygone age of surgery.[4] The pleural edge can easily be displaced by gentle gauze manipulation. My experience of the treatment of aneurysm and tumour at the root of the neck is confirmatory of this statement. The exception is the case of a malignant tumour to which the pleura is adherent. If the pleura is opened the opening should be closed and at the termination of the operation the air in the pleura should be aspirated so as to allow the lung to expand. In an operation on the heart of a dog this always has to be done, because in this animal the heart cannot be reached except by the transpleural route.

Baron Larrey's[5] case is of great interest because it is clear that it led him to experiment and to devise a new operation which anticipated Allingham's suggestion by about 90 years.

> Larrey's patient was a man, aged 30, who stabbed himself with a knife in the left side of the chest; the pericardium and the left lung were wounded, the knife had passed through the fifth costal cartilage and was still in the wound when he was brought to hospital. Frothy blood escaped in jets with each systole. The knife was withdrawn and the wound dressed with plaster; the patient tore off the dressing and it was reapplied. The pulse was rapid and there was grave dyspnœa. Bleeding gave some relief. Some improvement took place, but later on he became worse, and in great distress requested Larrey either to open his chest or to give him a narcotic strong enough to send him to sleep. Operation 45 days after injury, incision through skin and cellular tissue in fifth space below nipple, carefully carried deeper until pericardium felt. With the left index finger on the pericardium as a guide an incision into the pericardium was made with a bistoury, the finger inserted, and the apex of the heart felt. About a litre of fluid with some blood clot escaped. Great relief. In ten days the wound closed and the

---

[1] Private letter from Sir T. Clifford Allbutt.

[2] Some cases are recorded in Mr. Stephen Paget's admirable Surgery of the Heart, 1896, and there are many others in surgical literature.

[3] Voinitch contributed in 1897 a careful study of the variations in the normal position of the anterior margins of the pleuræ, especially with reference to operation on the pericardium. His paper is illustrated by numerous figures. He finds that there is a triangle of safety, so that the sternal portions of the left sixth and seventh cartilages can be removed without any risk to the pleura. Lietopsis Ruskoi Khirurgia, 1897, p. 805, Fig. 88.

[4] "The artificial separation of the normal pleura is usually possible, and in pyopericarditis is always to be attempted by the surgeon in order that the underlying pericardium may be divided and the abscess material be evacuated without risk of pleural contamination. Delorme and Mignon maintain that fluid distension of the pericardium has little effect in displacing the median pleural reflection outward; but Glück and Curschmann take the opposite view. Drainage in children may be interfered with by infection of the anterior mediastinum." Eliot: Cases of Suppurative Pericarditis. Annals of Surgery, 1909, p. 60.

[5] Bulletin des Sciences Méd., vol. vi. (1810) and Clinique Chi. (1829), vol. ii.

symptoms recurred. Wound reopened with a probe, 4 oz. of pus escaped. Considerable improvement. Death 68 days after injury and 23 after operation. Autopsy: Suppurative mediastino-pericarditis.

Remarks by Larrey.[6]

"In pericardial effusion ...... I should carry out the operation at the most dependent point of the pouch formed by that membrane, and this point, which may be termed the seat of election, corresponds, as we have said, to the interval between the left side of the base of the xiphoid and the united ends of the seventh and eighth left costal cartilages. It is in this triangular cellular space that an oblique incision may confidently be made from the junction of the seventh costal cartilage with the sternum along its inferior border as far as the end of the eighth costal cartilage, which is closely united by fibrous tissue to the seventh costal cartilage. In this incision, which divides some fibres of the first digitation of the rectus and of the external oblique, is included the lamellar fibrous tissue which is continuous with that which is called the false layer of the peritoneum, on division of which the prominent point of the pericardium, appearing in the interspace between the first two digitations of the diaphragm, is encountered. The point of the bistoury carried carefully upwards and a little from right to left will enter the pericardium without opening the peritoneum. A small portion of the anterior border of the diaphragm is just cut as it is attached to the posterior surface of the seventh cartilage. No important vessel is met with.

"Thus this operation, easy to execute, is of all the methods the least likely to wound the heart, and offers the greatest chances of success."

He adds in a footnote:

"The patient should be seated on the edge of his bed and should have something to lean against, because in this perpendicular position the anterior border of the base of the pericardium is more inclined forwards, and in consequence more accessible to the instrument."

The advantages of the operation, according to Larrey, are as follows:—

1. At this point the inner surface of the pericardium is the further away from the heart, the greater the amount of fluid in the cavity.
2. The opening being dependent the fluid escapes more easily and without embarrassing the heart's action.
3. That if there are adhesions they are usually absent from the region of the diaphragm.

Larrey says that he has repeatedly tried this operation on the cadaver, and that it can be done with precision and ease. The idea of it was suggested to him by a case in which a man had accidentally suffered a similar operation. This case was a man aged 22, who with his right hand stabbed himself under the seventh rib in a direction upwards and a little to the left. There was a considerable hæmatoma and hæmo-pericardium. Larrey evacuated the blood serum by enlarging the wound and inserting a catheter which reached the heart, and after some vicissitudes the patient got well. Larrey had several bodies placed in the erect position and stabbed in a similar manner, and found that the knife in every instance entered the pericardium, so the method of operation he describes was evolved, but he does not seem to have had an opportunity of practising it.[7]

Allingham[8] describes what he called "the epigastric operation" for drainage of the pericardium. The details seem to be somewhat similar to those suggested by Larrey. Allingham makes his incision along the lower border of the seventh cartilage and then works through the costo-xyphoid space to the under surface of the diaphragm. The pleura is thus avoided and the peritoneum is in no danger. In some cases he says it is desirable to resect the sternal end of the seventh cartilage.

Trousseau[9] lectured on paracentesis pericardii. He recommends the use of the knife.

"I cut through the successive layers of tissue separating them by means of a grooved director. At last the point of the bistoury having penetrated a little too far some slight red serosity spurted along the blade." "I would make my incision in the fifth, sixth, or seventh space near the sternum. If it were necessary I should not hesitate to remove a cartilage so as to allow the pulp of the finger to reach the pericardium. It is necessary to be assured that there is sufficient distance between the heart and pericardium."

Trousseau relates the instructive case of *Roux*.

"Roux proceeded with extreme caution and made the opening by incision in preference to puncture; the result testified to his sagacity. When he reached the pericardium and introduced his finger into the wound he felt the heart beating and slight friction between it and the pericardium, without, however, detecting the slightest degree of fluctuation. The operation was suspended. At the autopsy there was found phenomenal dilatation (dilatation phénomenale), to use Dr. Vigla's expression, with attenuation of the walls of the heart; there were no valvular lesions and no serosity in the pericardium."

Delorme[10] and Mignon give the following directions for opening the pericardium. They systematised surgical knowledge up to the date of their paper.

1. Make a vertical incision from lower border of seventh cartilage to upper border of the fourth cartilage, 1 cm. external to left border of sternum.
2. Dissect off soft parts from ribs and cartilages for 1 cm. towards middle line and for two fingers' breadth outwards.
3. Disarticulate and resect a piece of fifth and sixth cartilage.
4. Carry the incision through intercostal muscles and perichrondrium down to triangularis sterni.
5. With a director worked parallel to posterior surface of sternum detach insertions of triangularis sterni, then introduce finger and completely detach soft parts from posterior surface of sternum. Then seek the pericardium just above the insertion of the cartilages into the sternum, and separate it with the finger from the cellular tissue which covers it; then, when its opaque surface is clearly exposed and its transverse fibres recognised, continue the separation through the whole extent of the wound. Thus the pleura and the internal mammary vessels are displaced outwards and not seen.
6. Pick up the pericardium with the forceps and incise it.

2. PARACENTESIS OF THE RIGHT AURICLE AND VENTRICLE.

These are, I believe, dangerous and freak operations. No more benefit, it would appear, can be derived from their performance than by a free venesection from the external jugular vein. In cases of overloaded right heart many of us must have witnessed the relief given by the taking of two pints of blood from this vein.[11]

The hollow needle for puncture of the right auricle is introduced in the third right costal space close to the sternum. To puncture the right ventricle the needle is introduced in the fourth right intercostal space, 1 inch from the sternum. Suction is necessary in the case of the auricle in consequence of the low pressure in that cavity. Such operations are desperate remedies, but so also, it is only fair to add, is the condition of patients for whom such remedies would be thought of.

[10] Revue de Chirurgie, 1895.

[11] Dr. Sloan's case (1894) is of great interest (but in his patient the heart had ceased to beat). "I plunged the needle of an aspirator through the fourth space, half an inch to the left of the sternum, 10 ounces of pure blood flowed rapidly into the bottle. As I was slowly withdrawing the cannula the heart made first a feeble irregular movement, then gave a sudden strenuous jump, and finally, like a pendulum regaining its swing or a runner his stride, it started to beat again in the race for life." She slowly recovered and was restored to health. (Trans. of the Med. Chir. Soc. of Edinburgh 1894–5.)

3. OPERATION FOR AIR EMBOLISM OF THE HEART.

The suggestion has been made that the pulmonary artery should be clamped and that the air should be aspirated out of the two branches of the pulmonary artery on the same principle which led Trendelenburg to operate for obstruction of the pulmonary artery by clot.

When I was in Leipzig before the war Trendelenburg demonstrated his operation, and I have since several times practised it on the cadaver. The second left cartilage and a portion of rib is removed, the internal mammary artery tied, the pleura pushed away, the pericardium opened, and the circulation through the aorta and pulmonary artery arrested. The pulmonary artery is then incised and the clot removed by means of forceps. The aorta and pulmonary artery must not be obstructed for more than one and a half minutes. The operation of incising the pulmonary artery, removing the clots and clamping the opening in the pulmonary artery, can be accomplished in 40 to 45 seconds.[12]

4. CARDIAC STIMULATION FOR ARREST OF MOVEMENT OF THE HEART.

An epigastric incision is the quickest route to the heart, though several other routes have been recommended. Speed is an essential factor; massage must be commenced without any delay. The heart is held through the diaphragm near the apex by the thumb and finger and the ventricles compressed rhythmically from 30 to 40 times a minute.

Ricketts[13] reported 39 cases. Of these the heartbeat was permanently re-established in 12 (34 per cent.). In one of the successful cases the heart function had ceased for 20 minutes before it was re-established. The ages of the successful cases varied from 22 to 65 years.

Many other methods of cardiac stimulation have been proposed, but none can compare with the above in safety, in rapidity of execution, or in the success which has attended its employment. Crile has combined massage with arterial infusion towards the heart. I witnessed at Cleveland an experiment in which a dog's heart commenced to beat 30 minutes after death. Crile caused blood from another dog to flow down the carotid towards the heart, an anastomosis having been done between the carotids of a living and the dead dog. The dead dog recovered; indeed, in 20 minutes it was running about as if nothing had happened. Crile told me that if a dog was revived after 40 minutes of death its moral character was altered.

5. CARDIOLYSIS.

This operation, designed to free the heart from the rigid chest wall in front, especially when its action is hindered by adhesions, and to relieve an enlarging heart from the compression of a too confined space, is an admirable operation in selected cases. It has been proposed that adhesions between the parietal and visceral layers of the pericardium should be separated surgically (Delorme (1898) and Weill of Lyons (1895)). Also, in 1909, Leriche[14] considered the operation justifiable, but suggested excision of pericardium as better. Neither of these operations has been performed, and the possible utility is not apparent, for if adhesions were separated they would soon form again.

For mediastino-pericarditis, when the heart's action is hindered by adhesions, two, three, or more costal cartilages are removed. The first operations of this kind were done in 1902 by Peterson and Simon at the suggestion of Brauer.[15] Thorburn,[16] of Manchester, discusses the question and gives a table of 15 cases collected from literature. He gives one case done by himself, and refers to two others operated on by Stabb at the instigation of Alexander Morison.[17] Morison refers to a similar operation done for him to make room for an enlarging heart in a case of aortic stenosis. He suggests the same operation for mediastinal tumour, especially when the heart is interfered with.

Thorburn's cases number 18; of these, 6 cases were greatly relieved by the operation and in others the results were encouraging, but the exact details in some were not recorded.

6. OPERATION FOR INJURY OF THE HEART ITSELF: CARDIORRHAPHY.

A. *Some general considerations and statistics.*—Bullets or other foreign bodies[18] may lodge in the pericardium. They may be free or fixed to the pericardial wall or external surface of the heart. They may produce signs and symptoms or may remain for years in the pericardium inert and without being the cause of any bodily disturbance. The pericardium and heart have been wounded in various ways and by various missiles. The wound may or may not perforate the heart. Sharp-pointed instruments may or may not carry infection; bullets or metal fragments usually do. The operator may diagnose a wound of the heart, but subsequently a wound only of the pericardium, possibly associated with a superficial wound of the surface of the heart, may be found, or a wound of a coronary artery or of one of the great vessels may be present. In each of these cases blood will occupy the cavity of the pericardium. It must not be forgotten that hæmopericardium may be due to hæmorrhage from a vessel of the pericardium, and there may be no other source of bleeding.

With the filling of the pericardium with blood under pressure a great emergency in surgery arises. The auricles are compressed and signs of venous obstruction appear; there is great dyspnœa and cyanosis. The respiration is laboured and shallow and the pulse small, rapid, and of low tension. It is urgent freely to open the pericardium and to *decompress* the heart.

If the operation is performed at a later stage the pericardial sac will be distended, as in old hæmatomata, with a dark fluid, composed of serum secreted from the pericardial wall, old blood and some fresh blood. Again, as in my case, there may be no excess of fluid in the pericardium, and no appearance of sepsis. When infection has taken place before operation, or follows the removal of a bullet, the sac will contain purulent fluid. In some of the war cases the virulence of the infection was a marked feature.

[16] Brit. Med. Jour., 1910, i., 10.

[17] THE LANCET, 1908, ii., 7.

[18] Salamoni (1901) collected 91 cases of foreign bodies in the heart which had entered the heart through the chest walls, chiefly the pericardial region. Of these, 40 recovered and 51 died. Quoted from Matas.

The complication of a wound of the pericardium or of the pericardium and heart with a wound of the pleura, or pleura and lung, is frequent. There will then be besides hæmopericardium also hæmothorax and probably hæmopneumothorax. These complications only clinch the necessity for immediate action on the part of the surgeon. During the war massive hæmothorax has been best treated by widely opening the thorax and removing clots and blood. In hæmopneumothorax the condition of urgency is greater in consequence of the danger ensuing from displacement of the heart. The collapse of the lung is an important factor in the control of hæmorrhage from a lung wound. Any way, whether the bleeding threatening life is external or internal, the surgeon's first duty is to stop it.

The heart.—Sudden death from heart failure occurs from many causes, and among these are perforating and non-perforating wounds. Injury to the muscular bundle of His causes rapid death. A wound of an auricle is said by some to be more fatal than a wound of a ventricle, as the walls are thinner and have less tendency to close. A wound of the right ventricle bleeds more or less continuously, while a wound of the left ventricle may bleed intermittently. In my case the bullet nearly passed through the wall of the right ventricle, but its base was fixed in the inner part of the wall, so that there was probably no bleeding into the pericardium from the cavity of the ventricle. An aneurysm may form at the site of a cardiac wound as in any other part of the arterial system from the giving way of the scar tissue. At a later stage the sac may rupture and sudden hæmopericardium will result.

The following tables give the statistical results of Fischer, Borchardt, Rehn, Vaughan, Peck, and Pool.

Georg Fischer[19]*: Statistical Results before Operative Interference was Attempted.*

Punctured wounds	44	Gunshot wounds	72
Incised wounds	260	Crush of chest	76
Total		452 cases.	
Right ventricle	123	Interventricular septum ...	7
Left ,, ...	101	Entire heart	16
Both ventricles	26	Right side of heart	4
Right auricle	28	Left ,, ,, ...	5
Left ,, ...	13	Coronary artery	2
Apex	16	Unspecified	57
Base	3	Pericardium	51
Total		452 cases.	

In 47 cases foreign bodies were found in the heart: Needles, 18; bullets and shot, 13; various, 16.

Of the 452 cases—

Recoveries.		*Deaths.*	
Heart wounds	50	Within a few minutes	104
Pericardial wounds	22	Later	219
	—	Time not stated	57
Total	72		—
		Total of deaths ...	380

In the pre-operative period 85 per cent. died and 15 per cent. recovered. The 15 per cent. include needle puncture, from which the mortality is not great.

In Borchart's[20] list of 78 cases of operation there were 39 deaths, 21 of which were due to sepsis.

In Rehn's[21] list of 124 sutured cases the left ventricle was wounded in 55, the right ventricle in 50, the left auricle in 3, and the right auricle in 4; 15 of the cases were gunshot wounds, and of these 6 recovered. Suture of the left ventricle, according to Rehn, is more successful than suture of the right ventricle. This list of 124 cases shows 40 per cent. of recoveries. The great majority of the fatal cases were due to hæmorrhage or sepsis.

Vaughan[22] gives a list of 150 cases of suture of the heart of man. Of these 98 died, 44 died after the first 20 hours, mostly of infection. Of 133 patients in whom the situation of the external wound is known 130 were on the left side, including 52 through the fourth space and 36 through the fifth space.

Of 140 cases in which the weapon was indicated 16 were caused by bullets; 7 recovered, or a mortality of 56 per cent. Of 142 patients—

The left	ventricle	was wounded	in	68	cases.
,, right	,,	,,	,,	68	,,
,, left	auricle	,,	,,	4	,,
,, right	,,	,,	,,	4	,,

2 had each 2 cavities wounded, 1 both ventricles, and 1 right auricle and right ventricle.

From an examination of the statistical results Vaughan says: "The lesson taught is to do away with drainage."

Peck[23] reports a case of wound and suture of the right auricle. The patient was a girl of 24 and recovered. In this case the heart tamponade had been extreme. The pulse returned immediately the incision in the pericardium was made and 300 c.cm. of dark blood escaped. The tension in the pericardium was great and the blood escaped in a gush. He says that of the 11 reported cases of auricle wounds operated upon, 7 have recovered, a mortality of 36·3 per cent., while the general mortality is about 64 per cent. The consequences of hæmopericardium is to render diastole difficult and aspiration insufficient, whence a progressive and dangerous weakening of the blood pressure.

Peck, combining the statistics of Lenormant, Rehn, and Vaughan, gives 161 cases of suture of heart.

Wounds of right ventricle	69	with	48	deaths.
,, left ,,	74	,,	45	,,
,, ,, auricle	5	,,	2	,,
,, right ,,	6	,,	2	,,
Multiple wounds	7	,,	5	,,
	—		—	
Total	161		102	

Thus more than a third of all the cases recovered.

Pool[24] says the immediate results of non-operative treatment are very poor as compared with those obtained by operation. Moreover, although some heart wounds heal without surgical intervention, there is always danger of secondary hæmorrhage from an unsutured wound, and the spontaneously healed heart wound, even a non-perforating one, leaves a weak scar which may rupture or become the site of aneurysm. Loison, as early as 1899, collected nine such cases.

Pool gives a table of 77 cases of heart suture reported in 1909, 1910, and 1911, including earlier cases not previously reported; these supplement the tables published by Peck in 1909, and bring the total up to 236.

The transpleural exposure with long intercostal incision is recommended especially because in a large proportion of heart wounds the pleura is already opened. An extrapleural operation is possible in exceptional cases. Fine vaselined silk on a curved intestinal needle is the best material for heart suture. The pericardium should be closed with sutures. Pleural drainage as a prophylactic step is unnecessary and harmful. It is noteworthy that in Pool's case, as in mine, large quantities of clear fluid escaped at the first dressing.

Pool's paper was published in 1912. Between that date and the Great War (August, 1914) there were more than 75 operations on the heart. The mortality of these operations has been slowly decreasing since 1896. I think that the death-rate before the war may be put at about 45 per cent. Adding the cases during the Great War, which number over 60, we have a certain total of at least 380 operations on the heart. Since the performance of Farina's operation I have no doubt, however, that there have been many more than 400 operations on the heart to the present date. Many cases, especially the fatal ones, have not yet been published. Of 58 war cases of which I have notes 44 recovered and 14 died—a wonderful record! The French surgeons seem to have been very successful in these heart operations.

Hartmann's case:

Soldier, wounded at Bapaume, August 27th, 1914, and taken prisoner by the Germans. Very slight symptoms at first. In February, 1915, pain, palpitation, and dyspnœa. In August much worse; frequent heart attacks with sensation of impending death. X ray examination showed bullet in heart. Sent to Switzerland, where he stayed till February, 1917. After being in various hospitals he reached Paris, April 7th, 1917. Operation: Excision of 10 cm. of fifth cartilage and rib from sternal junction. Pleura opened. Projectile could be felt through pericardium; 6 cm. of fourth cartilage and rib excised to give more room. Heart's apex adherent to diaphragm by a band as thick as the index finger. When this was cut through heart could be lifted up. Then incision and extraction of ball from wall of right ventricle. Suture without drainage. Recovery.

Jenckel's case:

The bullet was embedded in the posterior wall of the right ventricle. Operation was done six months after the injury, but had to be abandoned because the heart could not be brought forward enough to expose the posterior surface of the ventricle; the patient recovered. After waiting six months Jenckel operated again, and this time succeeded in removing the bullet, and the man made a good recovery.

Beaussenat's case:

Soldier wounded at St. Hubert, Oct. 1st, 1914. Operation Sept. 17th, 1915. Bullet in right ventricle. Recovery.

During the war there have been several cases in which a bullet has been expelled from the ventricle of the heart. In 1916 Deneke removed successfully a bullet impacted in the right axillary artery. It came as an embolus from the left ventricle. It had been seen in the ventricle and afterwards was located again by the X rays in the axillary artery. In another case the bullet was lodged in the right subclavian artery and was removed through an incision made in the vessel, but the soldier died of sepsis and hæmorrhage; arteriorrhaphy was performed after removal of the bullet.

B. *The operation.*—There are three types of operation which are suitable in these cases. Much depends upon whether the external wound has to be enlarged or not, and whether the pleura and lung have been injured.

1. *The Delorme-Mignon-Kocher Operation.*

When the surgeon can ignore the external wound he will be likely to choose the Delorme-Mignon-Kocher incision over the pericardial region. A square flap of the soft parts is reflected outwards, the fourth, fifth, and sixth cartilages are removed, the internal mammary artery ligated, the triangularis sterni dissected away, and the edge of the pleura and lung retracted by gauze. The pericardium is then exposed, and should be divided so as to get as large an opening as possible.

I dislike the chondro-plastic flap of Kocher; such an operation in the desperate circumstances of a heart wound appears to be out of place. What does it matter that there is a gap in the chest wall afterwards if the patient recover? Further, a chondroplastic flap means that a dead space is left at the close of the operation under the flap which might determine the onset of sepsis.

2. *The Spangaro Operation.*

Spangaro makes a long incision in the fourth interspace and then divides or disarticulates the fourth and fifth costal cartilages at their union with the sternum, and in some cases also the sternal ends of the third and sixth cartilages may be divided. The fourth and fifth ribs are then forcibly drawn apart by a rib spreader and a fine view of the pericardium, pleura, and lung obtained. Not only by this method can the pericardium and heart be thoroughly explored, but the pleura and lung come under observation too, and the injuries of all are exposed in such a way as to make thorough surgical treatment easy and simple. The fifth intercostal space may be chosen if the surgeon prefers, and he will certainly do so if the wound is in this space. In a large proportion of heart wounds the pleura is opened, and in these the Spangaro operation is to be preferred. When the Spangaro operation is chosen the boundary of the pericardium on the left side back to the posterior surface can be brought fully into view. This allows, therefore, of an incision being made in the pericardium which will effectually drain the cul-de-sac of Haller.[25]

3. *The Duval Operation.*

Some of the French surgeons expose the heart by a *median thoraco-laparotomy* (P. Duval). A paramedian incision is made from the level of the third cartilage to a point midway between the xyphoid and the umbilicus. The abdominal cavity is opened and the diaphragm incised. The sternum is cut through below the third cartilage and split longitudinally for the rest of its length. The halves of the divided sternum are then forcibly separated and a wide exposure of the pericardium results. Some of the French successes during the war have been obtained by this method.

To sum up, the cardinal point to bear in mind is that the organs that have been wounded must be widely exposed. It does not matter what type of operation is chosen by the surgeon as long as this fundamental principle is not departed from.

4. *The Wound of the Heart.*

The wound of the heart may or may not be bleeding. If there is no serious bleeding the blood and clots can most readily be removed from the pericardium by pouring into the sac sterilised warm salt solution. The traumatism of sponging should be avoided. The cavity can be afterwards dried with gauze. The anterior surface of the heart is next inspected, and if no injury is visible a suture should be passed through the apex. The apex is then drawn forwards, so that the posterior surface of the heart can be inspected and palpated. This displacement of the heart does not disturb its action in any way. "The heart is not the delicate organ it was once supposed to be. it has an enormous capacity to withstand mechanical insult."[26]

---

[25] Poirier and Charpy's Traité d'Anatomie Humaine, 1912, T. II., F. II., p. 163. Known by English anatomists as the oblique sinus.

When the wound is found, interrupted sutures should be applied in the usual way. The case is otherwise when blood is rushing from the heart and no view of the wound is visible. Matas describes these circumstances as "imposing," and no doubt they are, but chiefly so because of one's want of experience. The surgeon having this job in hand will take it all in the day's work, and just as he plunges his hand into the abdomen into a mass of blood in a case of ruptured spleen, or in a case of ruptured tubal gestation and seizes the bleeding spot, so he will now plunge his hand into the pericardium and seize the heart, and, by digital compression, control the hæmorrhage, and proceed to suture the wound. I once in a case of ruptured innominate aneurysm blocked the lumen of the vessel with my finger till it was possible to pass a ligature around it just above the arch of the aorta, and I imagine the procedure in hæmorrhage from the heart would be of the same character.

When the cardiorrhaphy has been completed the pericardium is to be sutured. If drainage is desired indiarubber tissue should be used. Gauze acts like a cork, and there are obvious disadvantages and dangers in the use of a rubber tube. When there is profuse suppuration the edges of the opening in the pericardium should be stitched to the skin.

5. *The Removal of a Foreign Body from the Heart.*

Supposing the foreign body has been found to lie in one of the ventricles, a fixation stitch is passed through the apex; the heart is held in the left hand and the line of incision for the extraction determined on. A few Lembert sutures are now applied along the proposed line of incision, so that they may be drawn tight as soon as the foreign body is removed. The loops of these ligatures are pulled out of the way, the incision made, forceps introduced, and the bullet extracted. It is just as the bullet comes out that a rush of blood will be likely to escape from the heart, but this can be limited by the pressure of the thumb of the left hand on the ventricle just above the line of incision. The pulling of the Lembert sutures tight immediately arrests the bleeding. It is only when the blood escapes that the blood pressure falls; during all the rest of the manipulation the heart does not appear to be incommoded at all.

The story of the wanderings of foreign bodies and bullets in the vascular system of man is very remarkable. A bullet may perforate the heart or aorta without causing fatal hæmorrhage. The hepatic vein or vena cava may be traversed so that lodgment will take place in the right ventricle, or a pulmonary vein may be perforated so that the bullet is carried into the left ventricle. A bullet may wander along the great arteries till its progress is arrested by the diminished size of the artery. Further, the bullet may be ejected from the right ventricle into the pulmonary artery, or from the left ventricle into the aorta. A round bullet may remain loose in the ventricle and be whirled about by the blood current. All those events have been graphically described by Sir John Bland-Sutton,[27] and Dr. A. Fullerton[28] described a case in which a bullet was ejected from the right ventricle into the upper, main branch of the right pulmonary artery.

Radiography is of immense value in accurately locating metal fragments in the heart and elsewhere in the chest, but in certain very urgent cases the operation must be commenced in consequence of hæmorrhage or pressure of the blood in the pericardium before radiography can be used. When this happens and circumstances permit, the fluorescent screen should be employed to assist the operator during the course of the operation in the location of a bullet.

6. *The Wound of the Pleura and Lung.*

All blood must be removed from the pleura. The lung will be collapsed and there will probably be no bleeding. If there is a serious lung wound a few stitches may be desirable, but the wound should first be explored for the presence of a foreign body; such might be found and removed either in the pleura or the lung. I did not experience any case during the war of secondary hæmorrhage from the lung in cases of hæmothorax and hæmopneumothorax after the clearing away of clots and blood from the pleural cavity; so this supposed danger need not be considered. At the close of the operation the opening in the pleura should be closed. It is seldom necessary to aspirate the air from the pleural cavity; it is well to leave a wounded lung at rest for some days. Drainage of the pleural sac is generally advised, because the bullet or dagger is likely to have introduced infection into the wound; but this is a matter for the individual surgeon to decide at the time. The modern method of maintaining the expansion of the lung during operation might be of service in some cases, when the lung is not bleeding and where the urgency is not too great for the requisite preparations to be made.

The following case recorded by Launay[29] of recovery after suture of two revolver bullet wounds of heart is a good example of the value of the operation of suture of the heart.

Man, aged 26. Suicidal revolver wound. There were hæmopneumothorax, hæmopericardium. A wound both on the front and the back of the left ventricle was sutured by Launay. Both pericardium and pleura were drained. Recovery followed without serious complication. The bullet was retained; X ray examination showed it was lodged in front of the vertebræ.

Observations of Rehn and Zesas respecting Operations on the Heart and Pericardium.

Rehn[30] says:—

Needles should be at once removed, larger objects, such as broken pieces of knives, daggers, &c., not until the heart is freely exposed, or at least not until all preparations are made to operate forthwith. In apparently moribund cases the heart sometimes begins to beat again directly the pericardium is incised; so that an operation begun without anæsthesia has to be continued under an anæsthetic. All cases of injury with symptoms of heart compression require at least incision of the pericardium. We cannot know whether it is a perforating wound of heart or a wound of the coronary artery. We only know that it is our duty to operate. No single method of operation is applicable to all cases. Preservation of a bony covering to the heart is the least important matter. In every case it is better to resect several ribs than to make a large flap of bone, cartilage, and soft parts. The pleura seldom escapes injury in wounds of the heart. It is not always possible to operate extrapleurally. Commence by intercostal incision in situation of wound; if there is no wound operate in the fifth space. If hæmothorax or pneumothorax is already present go straight through into pleura, seize lung and displace it outwards. If not enough room make a second incision in middle line, detach cartilages from sternum, and retract ribs and soft parts upwards and downwards.

[30] Archiv für Klin. Chirurgie, vol. lxxxiii.

Zesas[31] expresses the opinion that removal of foreign bodies in the heart is always indicated. In 118 cases 96 were through the chest wall, 12 came from the alimentary canal, 4 by way of blood stream, and 1 from the air-passages. There were needles in the heart in 54 cases, bullets in 38. Besides these, nails, thorns, iron pegs, splinters, and hairpins have been found. Hoch found a nail embedded in the heart of a man who died of unrelated disease. In Manteuffel's case, after the wound of entrance was sewn up on the anterior surface of the right ventricle, the bullet was removed by an incision of the posterior surface. The patient was a woman aged 21 and made a good recovery.

(To be concluded.)

EXPERIENCES OF
MALARIA IN THE EGYPTIAN EXPEDITIONARY FORCE.

BY PHILIP MANSON-BAHR, D.S.O., M.D., M.R.C.P.,
BREVET MAJOR, R.A.M.C.; ASSISTANT PHYSICIAN, ALBERT DOCK HOSPITAL; AND LECTURER, LONDON SCHOOL OF TROPICAL MEDICINE; LATE OFFICER IN CHARGE OF MALARIA STATIONS, E.E.F.

THE following summarised account of malaria in the E.E.F. deals mainly with epidemiological points of interest, the mechanism for microscopic diagnosis on a large scale under active service conditions, and the gross pathology of the pernicious cases, in so far as it has a bearing upon treatment. These observations have been made whilst serving with the Force during the last three and a half years. I divide my observations into two portions, the first of which concerns Egypt and the Canal Zone, the second Palestine.

The malarial fevers in both these regions are caused by two species of parasites—the benign tertian and the malignant or subtertian. The quartan, on the other hand, would appear to be almost non-existent in Egypt and to occur but rarely in Palestine.

Malaria in Egypt.

During the summer of 1916 but few cases of malaria were seen; those from the Delta were all of the benign variety, but one fatal unrecognised malignant case from Ismailia came under my notice.

1. *The Canal Zone.*—In August and September, 1916, I was investigating malaria in the southern sector of the Canal Zone, and collected notes of 100 cases among British troops, all fresh infections contracted in that zone of operations.

The special points to note were:—

(*a*) No fresh infections were recorded before the first week in June.

(*b*) Malignant malaria did not commence till August and reached its maximum in September.

(*c*) The difficulty in recognising malignant malaria from a clinical point of view. There were three fatal cases, all of which had been primarily diagnosed as sunstroke.

(*d*) The scantiness of the malignant parasites in the peripheral blood in the early stage of the disease and their tendency to cling to the edge of the red cell (accolée forms); this renders their detection more difficult.

(*e*) The relative scarcity of anopheles. The most abundant species were *Cellia pharoensis*, *A. turkhudi*, *A. mauritianus*.[1] The former two species bred in the borrow-pits in the vicinity of the Sweet Water Canal and in the "seepage" water derived from the subsidiary channels, but, owing to the large numbers of surface-feeding fish, not in the canal itself. The latter bred in highly saline water in the vicinity of the Bitter Lakes. *Cellia pharoensis* is a well-recognised carrier of the benign parasite, while *A. mauritianus* has never been proved capable of acting as an intermediary. Experiments on actual transmission of the malignant parasite demonstrated the suitability of *A. turkhudi* to act as an intermediary, while *Cellia pharoensis* was proved to be but a vicarious transmitter of this disease.[2]

(*f*) Carriers of the malignant parasite were proved to exist amongst the wandering Bedouins, as well as the Indian troops and employés of the Suez Canal Company.

2. *The Fayoum* (Senussi campaign).—A number of cases of malaria occurred amongst the cavalry stationed in this western oasis in November, 1916. The existence of two malignant cases was established by a microscopical examination; the great majority were benign. The most abundant species of anopheles was *Cellia pharoensis*.

3. *The Western Oases* (Dahkla) (Senussi campaign).—The Dahkla Oasis, a notoriously malarial spot, was occupied by the mounted troops in December, 1916. In January, 1917, a number of subacute cases of malaria occurred amongst the troops ten days after their arrival in the oasis. Special points to note were:—

(*a*) The fact that malignant malaria could be transmitted during the winter season when the surface temperature of the sand at night-time was as low as 1° C.

(*b*) The mild nature of the cases and the scantiness of the parasites in the peripheral circulation; often rings were not found till the third day of the pyrexia. Many cases were not diagnosed by the presence of parasites at all, but by the rapid increase in the large mononuclear cells, which rose as high as 35 per cent. Absence of a palpable spleen in these early cases was also noted.

(*c*) The high rate of infection amongst the native population. The splenic index of the children under 14 was 96·4 per cent.; the parasite rate was 59 per cent., all parasites being of the malignant variety.

(*d*) The mosquito intermediary was *A. palestinensis*[3] (differentiated from *A. turkhudi* by the white tips to palpi). Large numbers of these insects were breeding in the warm springs (temperature 80° F.) which water this oasis throughout the winter.

(*e*) The liability of clinicians, in the absence of a microscopic diagnosis, to mistake mild relapsing cases of this nature for relapsing fever or enteric.

Malaria in Palestine.

During their progress across the Sinai Desert no indigenous malaria occurred amongst the troops. After occupying the line of the Wady Guzze a few cases of locally contracted benign malaria were

---

[31] Fortschritte der Medizin, Band xxviii., No. 21, S. 649, 1910.

[1] In the desert on the eastern side of the Canal, where wells occur, as at Ayun Musa, the former two species were found breeding abundantly in the clear well water.

[2] Journal of the R.A.M.C., June, 1918, p. 606.

[3] According to Storey (Entomological Department, Cairo) it is possible that this species is merely a variety of *A. turkhudi*, while the Palestine form, or the true *palestinensis*, is distinct.

noted in August, 1917, but owing to the vigorous antimalarial measures taken they never reached any large numbers. In September a few malignant cases occurred with one death from coma. Once again the fact was impressed upon my mind that the nature of the illness had not been recognised till too late. Five cases with dysenteric symptoms due to malarial enteritis were seen, accentuating the necessity of distinguishing this complication from the more usual forms of dysentery.

1. *Experiences in 1917.*—Immediately after the successful military operations at Gaza in November, 1917, it became evident that the main body of the E.E.F. had moved forward into a highly malarial zone. From the available medical literature procurable dealing with this matter (Masterman, Huertemueller, Mühlens) it was ascertained that malaria, especially of the malignant variety, occurred along the whole zone from Jaffa to Jericho, and was apt to assume epidemic form during the autumn months, especially mid-October. In November and the early part of December a number of unrecognised and often fatal cases of malignant malaria occurred, and in the middle of December I performed six autopsies on cases with varying original diagnoses, such as debility and influenza. Such a large number of febrile cases occurred, all from two infantry brigades which were then holding the Auja line and which proved to be malignant malaria, as to warrant the suspicion that the infection had been locally acquired during the winter months. This was confirmed by subsequent work at Jaffa during January, 1918, and three more fatal cases occurred.

The main points noted in this connexion were:—

(*a*) The anopheles infected during the previous autumn appeared to be capable of conveying the infection during the winter to troops quartered in

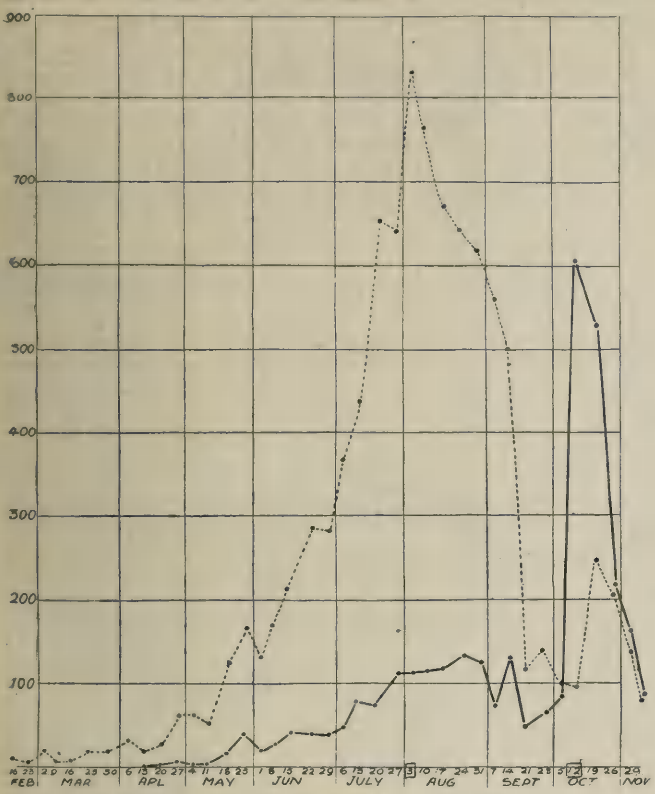

FIG. 5.—*Weekly Malaria Graph of the E.E.F. in Palestine, Western Sector of the Front (Jaffa to Ludd, 1918).*—This graph shows the epidemic of benign tertian malaria, beginning in June and reaching its maximum on August 3rd, 1918 (850 cases per week). *Anopheles maculipennis*, probably the intermediary host, appeared for the first time in large numbers on June 2nd, and extensive anti-malarial operations (draining of the marshes) were completed July 15th. The effect of these measures is well shown by the great fall which took place early in September. The epidemic of malignant tertian malaria follows later and coincides with the advance into enemy territory—i.e., the Plain of Esdraelon—which, being in Turkish hands, was unsanitated in the malarial sense. The maximum of this epidemic was reached on Oct. 12th (600 cases per week). These figures deal with fresh infections and not relapses.

These graphs have been constructed from 111,261 microscopic blood examinations performed by different military laboratories on this front within six months, of these 40,168 were undertaken by the six malaria diagnosis stations in the front line. The important dates are emphasised in brackets in the graph. The total force, British and Indian, employed comprised about 300,000 men. The dotted lines indicate benign, the continuous malignant malaria.

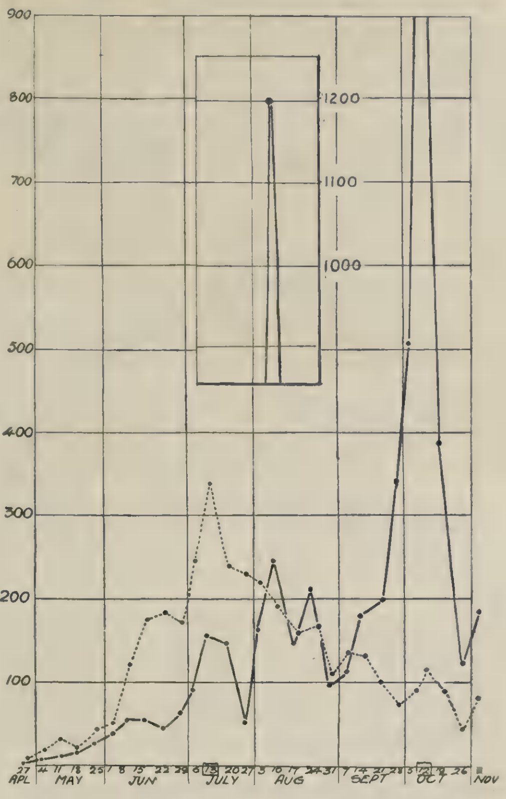

FIG. 6.—*Weekly Malaria Graph, Eastern Sector of the Front (Jerusalem to Jordan Valley).*—This graph shows a small preliminary epidemic of benign tertian malaria, reaching its maximum nearly a month earlier than on the Western side—i.e., July 13th. There is a tendency for malignant tertian malaria to predominate in the latter part of July and August, but, owing to the anti-malarial measures taken, it never assumed epidemic form. The great epidemic took place when the desert corps moved forward on the east side of the Jordan to Amman, and reached its maximum on Oct. 12th, after the occupation of Damascus (1200 cases per week). *Anopheles palestinensis* was the mosquito host and first appeared in large numbers about the middle of June and reached its maximum prevalence in October. These figures also deal with fresh infections. The occupation of Damascus was effected on Oct. 2nd, exactly ten days after the concentration at Beisan, where the actual infection was contracted. This period would appear to be the incubation period of malignant malaria.

native houses. The cases mostly came from two infantry brigades who successfully held the same portion of the line (Auja River) and occupied the same billets.

(*b*) Female anopheles (*A. bifurcatus*) were proved to be capable of laying ova during the winter season, and these ova were capable of hatching out and producing active larvæ in sheltered places, as in deep wells.

(*c*) The serious nature of the malignant infections. Three sudden deaths occurred a few hours after admission to hospital; autopsies were performed and large numbers of parasites demonstrated in the tissues. The alarming nature of these fulminating cases can hardly be realised. One man was found dead on the march after a halt, while two others died three hours after admission to hospital.

(*d*) The pleomorphic clinical forms which malignant infections could assume.

2. *Experiences in 1918.*—It became very probable that front line units would have to pass the greater part of the summer months in a highly malarial region, of which undoubtedly the worst areas were the Maritime Plain to the north of Jaffa and the tropical belt of the Jordan Valley.

It was realised that, though the incidence of the disease and the occurrence of pernicious and fatal forms could be minimised much by sanitary measures whilst the troops were stationary, yet the task was one of great magnitude, and the occurrence of a considerable number of cases could hardly be prevented in such a highly infected country; furthermore, that directly an advance was made further to the north sanitary precautions would become unavailing. The German statistics compiled in 1912 indicated that an epidemic of malignant malaria occurred in the autumn months, about mid-October (similar graphs have been recorded by Armand-Delille from Salonika).

Formation of malaria diagnosis units.—Realising that the safest plan in dealing with malignant malaria on a large scale consisted in early microscopic diagnosis, special mobile diagnosis units were formed, so as to ensure early diagnosis and early treatment. Six of these units, called malaria diagnosis stations, were formed, consisting each of one medical officer and two R.A.M.C. privates, who were given a month's special training in microscopic blood diagnosis and, when efficient, were distributed two to each corps. By the end of April, 1918, they were at work along the whole of the line. The equipment was of a portable and very simple character capable of being loaded on one G.S. wagon with four horses. The best form of portable tent for the purpose was found to be the I.P.G.S., 160 lb. The essentials provided were:—Tables, G.S., 3; forms, G.S., 3; lamps, hurricane, 3; microscopes, 2; and a supply of standardised Leishman's stain slides, distilled water, and spirit lamp. Central depôts for the further supply of reagents were formed at Ludd and Jerusalem.

The standardised Leishman's stain for issue to these units was prepared as follows:—Leishman's stain, 1 g. (Baird and Tatlock); Abs. methyl alcohol 200 c.cm.

The Leishman powder (1 g.) is placed in a glass mortar, 20 c.cm. of methyl alcohol are added, and the powder is ground down with a pestle until the alcohol is saturated. The fluid is now decanted off into a clean bottle and a further 20 c.cm. of methyl alcohol added to the residue in the mortar, which is again ground with the pestle until as much as possible is dissolved. The process is repeated, using successive fractions of methyl alcohol, until the whole of the powder is in solution. The volume is made up to 200 c.cm. finally with methyl alcohol, and 12 drops of a 1 per cent. NaOH solution are added and well shaken.

The method of staining adopted is as follows: The best portion of the blood smear is selected and marked off with a grease pencil. (The grease pencil marks confine the stain to that particular area of the slide, and when dealing with hundreds of films this practice effects a considerable saving of stain.) Raw Leishman's stain is dropped on to the slide by means of a pipette provided with a rubber teat; this is left for about 30 sec., the stain on the slide is now diluted with distilled water about 1 in 4 and left for a further 2–3 min. At the end of that time the stain is washed off with distilled water and the slides are arranged in a sloping position to drain and dry. The teat pipette was used throughout the process, both for adding the stain, for diluting the latter with distilled water on the slide, and for finally washing off. This method made for far greater economy of materials and cleanliness than would have been the case if a "drop-bottle" had been used.

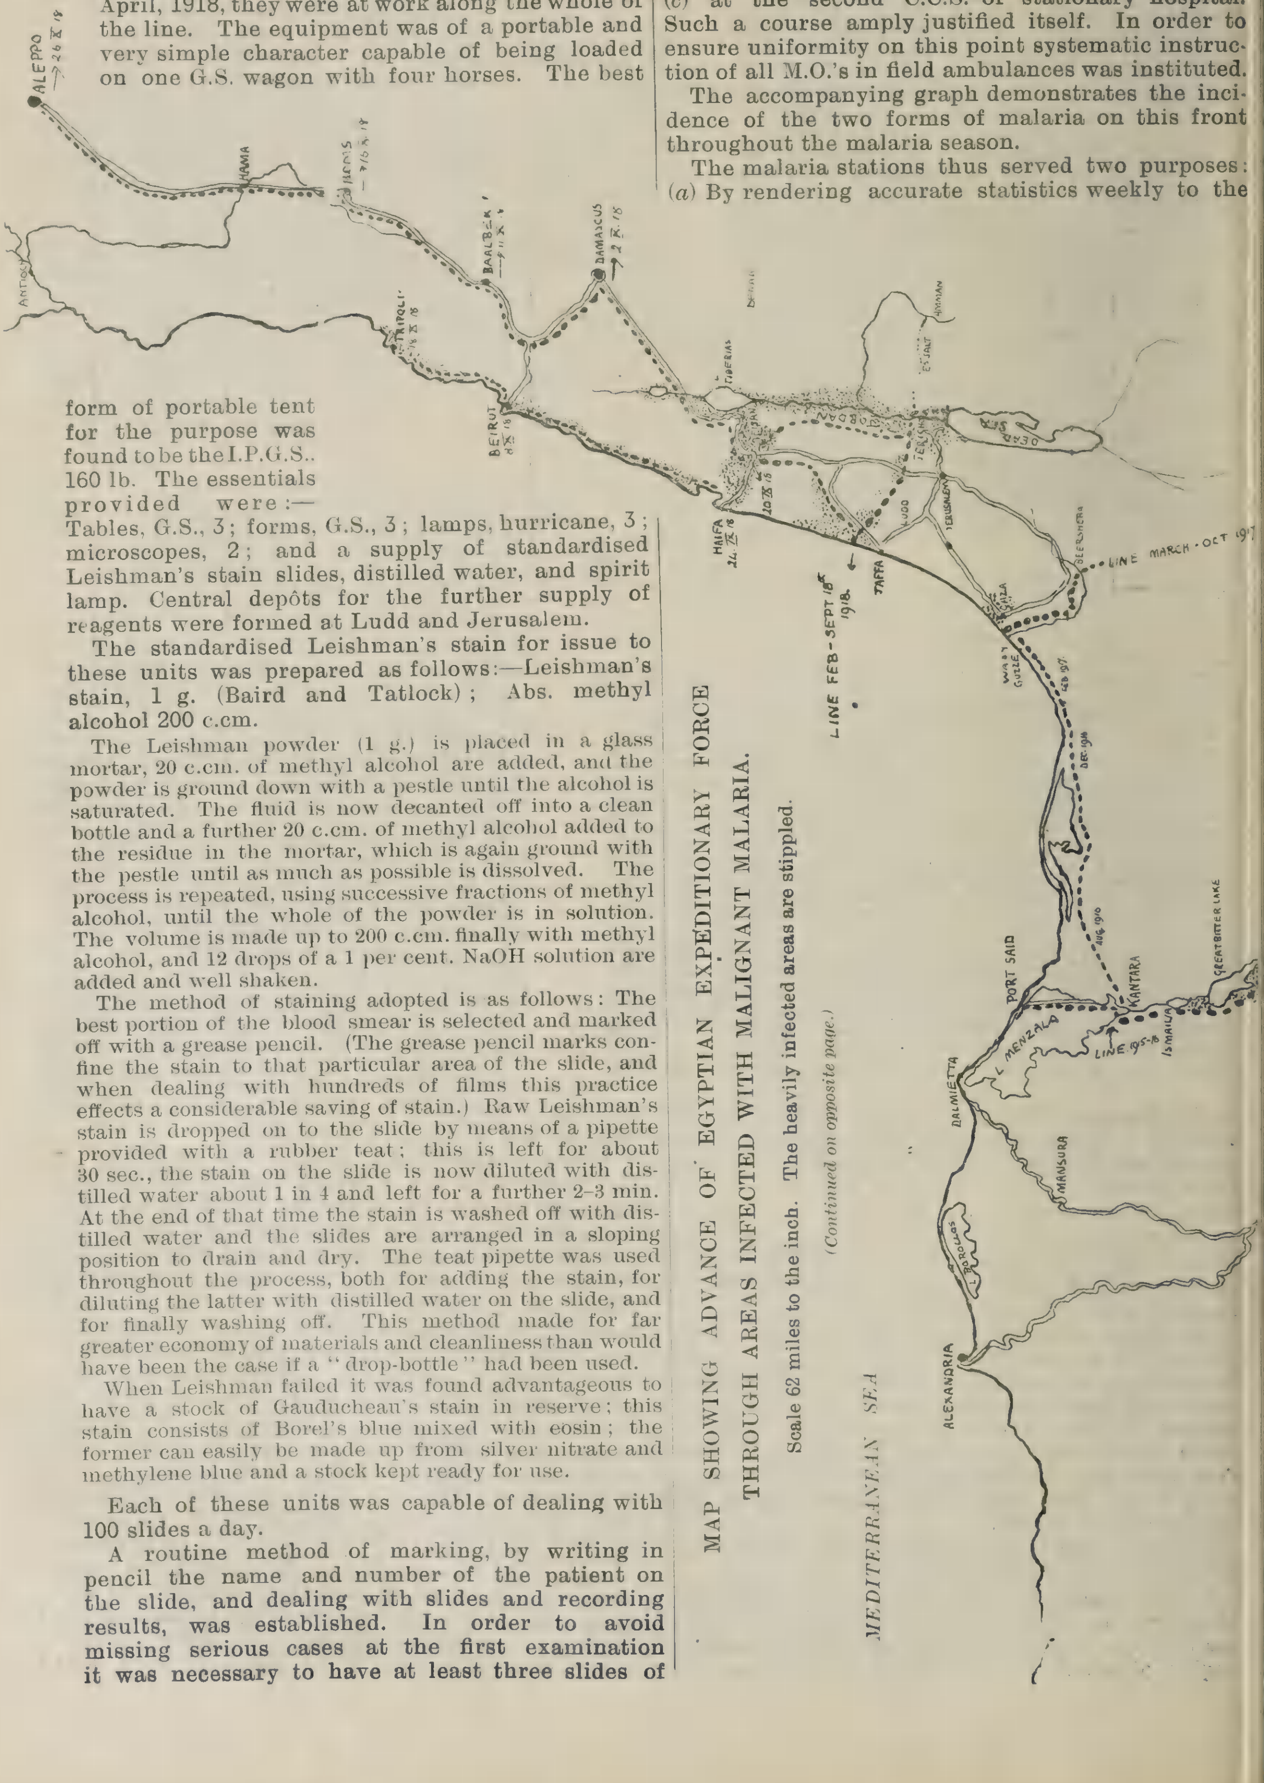
When Leishman failed it was found advantageous to have a stock of Gauducheau's stain in reserve; this stain consists of Borel's blue mixed with eosin; the former can easily be made up from silver nitrate and methylene blue and a stock kept ready for use.

Each of these units was capable of dealing with 100 slides a day.

A routine method of marking, by writing in pencil the name and number of the patient on the slide, and dealing with slides and recording results, was established. In order to avoid missing serious cases at the first examination it was necessary to have at least three slides of the same case examined at different periods before pronouncing a negative result. This was done (*a*) at the diagnosis station, (*b*) at the first C.C.S., (*c*) at the second C.C.S. or stationary hospital. Such a course amply justified itself. In order to ensure uniformity on this point systematic instruction of all M.O.'s in field ambulances was instituted.

The accompanying graph demonstrates the incidence of the two forms of malaria on this front throughout the malaria season.

The malaria stations thus served two purposes: (*a*) By rendering accurate statistics weekly to the



MAP SHOWING ADVANCE OF EGYPTIAN EXPEDITIONARY FORCE THROUGH AREAS INFECTED WITH MALIGNANT MALARIA.

Scale 62 miles to the inch. The heavily infected areas are stippled.

(*Continued on opposite page.*)

A.D.M.S.'s of the divisions and to the D.D.M.S. of the corps of the number of fresh infections occurring in different units, the type and *location* of the infection could be ascertained and steps taken accordingly; (*b*) ensuring, by early diagnosis, the *early exhibition of quinine by the intramuscular* route to all serious cases.

Classification of Clinical Symptoms of Malignant Malaria.

The experience gained of malignant malaria and the clinical forms it may assume can be classified as follows:—

I. *Pernicious or Rapidly Fatal Forms.*

(*a*) Cerebral (generally occurring in the summer).

Primary Clinical Diagnosis.	*Corresponding Clinical Variety of Malignant Malaria.*
"Sunstroke;" "heatstroke."	Comatose or delirious type, with hyperpyrexia.
"Mental derangement."	Maniacal type, with tendency to suicide.
"Epilepsy."	Epileptiform type.
"Cerebro-spinal meningitis."	Cerebral type.

(*b*) Abdominal (generally occurring in the winter).

"Dysentery," with blood and mucus.	Dysenteric type.
"Cholera" or "paracholera," with diarrhœic fæces and incontinence.	Choleraic or algide form, with subnormal temperature and collapse.
"Intestinal obstruction."	Condition due to gross infection of intestinal capillaries by malignant parasites.
"Appendicitis" or "cholecystitis."	Various forms of referred abdominal pain in malignant infection.

(*c*) Pulmonary (with pulmonary symptoms).

"Bronchitis"; "pneumonia"; pleurisy.	Malarial pyrexia, with pulmonary congestion and cardiac distress due to myocarditis. Pain over left hypochondrium, due to rapid enlargement of the spleen.

(*d*) Cases with skin lesions.

"Purpura" or "measles."	Septicæmic type of malignant malaria with multiple cutaneous hæmorrhages.

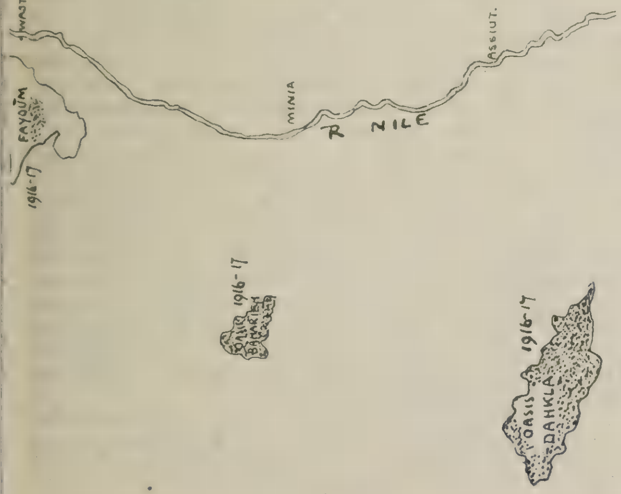
II. *Clinical Types of Average Severity.*

(*a*) Influenzal or myalgic.

"Influenza" or "rheumatism."	Pyrexia with joint pains.

(*b*) Enteric with steppage rise of temperature.

"Enteric," "sand-fly fever," "trench fever," "relapsing fever."	Splenomegaly with pyrexia.



(*c*) Icteric with bilious vomit.

"Jaundice" or "infective jaundice."	Bilious remittent form, with vomit of bile or "coffee grounds," remittent pyrexia, and hæmolytic icterus.

(*d*) Nephritic.

"Acute nephritis."	Albumin, blood, and pus cells in urine.

III. *Sequelæ.*

(*a*) Cachexia and anæmia.

"Pernicious anæmia," "leucocythæmia," "debility."	Enlarged spleen and great anæmia due to blood destruction.

(*b*) Blackwater fever (methæmoglobinuria).

"Hæmaturia."	Methæmoglobinuria and pyrexia.

In accounting for the comparatively high proportion of pernicious forms of malignant malaria in Palestine the probability of different *strains* of the parasite in different countries and their effect upon the human body must not be lost sight of. A similar analogy exists in the case of trypanosomiasis.

At the time of the advance on Sept. 19th/20th, 1918, the number of malignant tertian cases diagnosed by laboratories and diagnosis stations was, on a weekly average, 60 on the line Jaffa-Ludd and over 200 on that part of the line extending from Jerusalem to Jericho. At the beginning of October a very marked increase in the number of cases was noted, which reached its maximum in the week ending Oct 12th, when 1800 fresh infections were recorded. At the same time the clinical type of the disease was a very severe one, and there were many fatal cases. The diagnosis stations attached to the cavalry divisions were able to accompany them to Damascus. Their presence there was very necessary. A large number of serious cases developed soon after the occupation of that town and there was a tendency for medical officers to diagnose them on clinical grounds, especially from the associated diarrhœic symptoms, as dysentery. The majority of these infections appear to have been contracted in the plain of Esdraelon, and especially during the concentration around Beisan. The advance from this latter place to Damascus occupied 10 days—the incubation period of malignant malaria. The Anzac division operating on the right of the Jordan towards Es Salt and Amman also suffered heavily.

The situation was, moreover, complicated by the presence of the influenza epidemic, thus rendering a diagnosis of malignant malaria, without microscopic aid, almost an impossibility.

The Chief Points Summarised.

The following summary of the chief points in connexion with malaria in Palestine in the summer of 1918 may be given.

1. On the seaboard and the plain of Sharon the benign variety predominate, while east of Jerusalem the converse was the case, with a tendency for the malignant disease to assume epidemic form in the autumn months, especially mid-October. (M.T. malaria is endemic in the Jordan Valley; the splenic index of native children in Jericho was assessed as 65 per cent. and the parasite rate 54 per cent., mostly of the malignant type.)

2. The main mosquito intermediary in the benign tertian zone appears to be *A. maculipennis* and in Jordan Valley *A. palestinensis* (other anopheles found were *A. superpictus* (or *A. sinensis*), *A. fragilis* *A. bifurcatus*, and *A. turkhudi*)

3. The incubation period of malignant malaria in epidemic form is one of from 10–14 days.

4. The efficacy of early intramuscular quinine (gr. xii. in 2 c.cm. saline) early in the course of the disease. (A point to note in the distribution of quinine is that ampoules containing sterilised solutions of quinine should be supplied to front line units, while stationary, or general hospitals can more advantageously utilise sterilised solutions of quinine made up in vaccine bottles with rubber caps.)

5. The fatal nature of the infection if undiagnosed and untreated for a period of five days.

6. The most acute cases die of heart failure (apparently a toxæmic myocarditis), and therefore stand rapid evacuation badly.

7. The undesirability of intravenous quinine in acute cases with cardiac involvement: owing to the large numbers of parasites in the peripheral circulation it would appear that injection of large doses of quinine by the intravenous route destroys them with great rapidity, and in so doing floods the body with liberated malaria toxins which completely paralyse the cardiac mechanism.

8. The mechanism for early diagnosis and early treatment broke down on a rapid advance into a highly malarious country, with a consequent great increase in the number of fatal cases and pernicious infections.

9. The malignant tertian infection is much more amenable to quinine treatment than is the benign. This may sound paradoxical, but in the case of the former parasite it is a case of either kill or cure, and it is a remarkable fact that in Jordan Valley malignant infection relapses were not frequent. Very often a primary infection when treated early with quinine appeared to die out entirely. On the other hand, the benign infection, though amenable to quinine for the time being, relapses only too often in spite of it, and is therefore from a military point of view in many ways the greater obstacle of the two.

Bearing of the Pathology upon Treatment of Pernicious Forms of M.T. Malaria.

In the official returns for the whole force from May to end of December, 1918—i.e., eight months—the number of deaths proved to be due to malignant malaria was 853; of these, 75 were recorded during the first five months, and 773 during the last three—that is, subsequent to the advance into Syria.

The following is a summary of 67 consecutive post-mortems on malaria cases performed at Ludd during the period Oct. 1st to Nov. 8th, 1918.

Uncomplicated malignant malaria, 35.
Complicated by influenzal broncho-pneumonia, 32.

Of these *uncomplicated* M.T. malarias: (*a*) died in collapse with right heart failure, 24; (*b*) died with generalised hæmolytic icterus, 8; (*c*) died in coma with œdema of brain and blood-stained fluid in ventricles, 3.

In only four cases could parasites be demonstrated in the tissues, none of which had been adequately treated with quinine. There were four cases of terminal secondary infection with staphylococci, streptococci, and pneumococci. In no case had the diagnosis of malignant malaria previous to death been made without microscopic confirmation. Nor did any case come to autopsy in whom the infection had been missed during life after the adoption of the three-slide rule.

The first point to note is the evidence of a malarial toxæmia as against the hitherto accepted theory of a mechanical obstruction of the capillaries by the malignant parasite. For instance, no such obstruction could be substantiated in cases with cerebral involvement after quinine treatment. The œdema of the brain, the increase in the cerebro-spinal fluid suggest lumbar puncture as a means of alleviating urgent symptoms. (This was adopted by some clinicians with a fair amount of success.) The tendency to mental derangement[4] and suicide in malignant cases must be borne in mind. Heart failure has been mentioned and emphasises the paramount importance of *rest* in all malignant infections. The toxæmic cases with generalised hæmolysis indicate the close relationship between this type and blackwater fever, and consequently their treatment on similar lines.

It was demonstrated that three intramuscular quinine injections of gr. xii. each, on three separate consecutive days, cause not only a complete *temporary* disappearance of the parasite from the blood-stream, but also, after this amount had been absorbed, the size and condition of the spleen rapidly returns to normal. Therefore more frequent injections are not indicated in order to overcome the acute crisis of the disease. On the other hand, intravenous salines (1–2 pints) are indicated as a means of eliminating the toxins, and in cardiac cases in which there is engorgement of the right heart, abstraction of venous blood previous to this injection.

The adoption of this line of treatment was distinctly favourable in the few apparently desperate cases in which it was tried. Two German prisoners, for instance, who had remained comatose for two days in spite of quinine, recovered completely with intravenous saline without any further administration of this drug.

The Effects of Intramuscular Quinine upon the Tissues.

Observations were made at autopsy upon cases injected intramuscularly with quinine (quinine bihydrochloride gr. vi. to saline 1 c.cm.). Within four hours of injection, on incising the gluteus, a considerable serous effusion could be demonstrated in the muscle. Within 24 hours a superficial grey necrosis of muscular fibres was evident, but within the next few days these effects were no longer visible.

The effects of continuous injection at the same site were different; patches of necrotic tissue about the size of an almond, often communicating with other loculi of the same nature, could be demonstrated. Sometimes these cavities were occupied by blood clot, but more often by dead muscular fibres of a dark brown or greenish hue. *There was no evidence of pus formation.* Extensive necroses were most often observed when the injection impinged on the ilium itself. In one fatal case there was a generalised streptococcal infection of the necrotic tissue, probably of hæmic origin, as there was no evidence of any external infection obtainable.

The general indications are that continuously repeated intramuscular quinine injections in debilitated, anæmic, and emaciated subjects are to be avoided, if possible, as being liable to cause extensive necrosis of the muscular tissue. It must be remembered that the blood-forming mechanism of the bone marrow is inhibited by the malarial toxins and renders the body more liable to secondary infections of all kinds.

---

[4] Three cases which came under observation were so odd in their behaviour that they had been regarded by their regimental officers as men whose minds had become deranged by the stress of battle.

The suggestion is that greater dilution of the quinine for intramuscular injection would be followed by better results, but this is hardly practicable in the routine treatment of so many cases in C.C.S.'s on a large scale.

The moral of all this is that intramuscular quinine judiciously administered has its distinct beneficial usage, but it is open to *abuse.* There is no advantage in making one's patients' buttocks into pincushions, and one should remember that it is worse than useless to continue exhibiting quinine by this route after the parasites have disappeared from the circulation. One must treat one's patient, as well as destroy his parasites. The lesson is that a few injections of quinine are capable of destroying all the parasites in the spleen and of reducing that organ to normal size.

Defects of Scheme for Early Diagnosis and Treatment of Malaria in Palestine in 1918.

The main defects in the scheme I have outlined are that provision for diagnosis was not sufficient to meet the needs of the moment on such an extensive and rapid advance into enemy territory as that of September, 1918. The difficulties of continuous supply of the diagnosis units 200 miles from the base were considerable, nor was it possible for them to examine slides for field ambulances scattered over so wide an area.

Remedies Suggested.

That each field ambulance in an Eastern theatre of war should have on its strength one medical officer specially trained in the microscopic diagnosis of malaria. His equipment need be very simple and consists of a microscope and minimal requirements of slides, stains, &c. Attached to him there should be an orderly specially trained in this microscopic diagnosis, in which it has been proved that an R.A.M.C. private of average intelligence can become expert after a month's continuous training.

That to each corps there should be attached one expert pathologist to supervise the scientific work of these officers. That he should be provided with a Ford box-car fitted up with cases containing spare microscopic parts, Leishman's stain, slides, distilled water, spare hypodermic syringes, syringe needles, and quinine ampoules. He should be so situated as to be able to supply any deficiencies at a moment's notice and, at the same time, to be very mobile.

That a uniform method of recording results and quinine treatment upon field medical cards should be adopted. These should be stamped in indelible ink and different symbols for the designation of malignant or benign infection utilised. When written on in pencil, as is so frequently the case, the *primary diagnosis*, which is so important, is apt to be rubbed off as the patient is evacuated down the line.

It is most important, and I do not think this is sufficiently realised, that a primary microscopic diagnosis once made must be adhered to.

Advisability of Adopting a Standard Method of Differentiation Between the Parasites.

It is suggested that standard rules for the differentiation of the two main forms of parasite be adopted. The main points are that the benign tertian parasite invariably enlarges the red cell which it inhabits. This is a much safer rule than the presence of "Schüffner's dots," which are not invariably present in early infections. On the other hand, the points of importance in connexion with the malignant parasite are: (*a*) Its smaller size; (*b*) no alteration in size of red cell; (*c*) tendency to multiple invasion of same red cell; (*d*) presence of two nodules of chromatin.

It must be remembered that in the very heavy acute infections further developmental forms of the malignant ring may be seen in the peripheral blood, such as immature schizonts and gametes. Even sporulating forms of this parasite were found on two occasions in the peripheral blood—an extremely rare occurrence. These are apt to be confused with the quartan parasite. Possibly this fallacy accounts for the comparatively high proportion, 25 per cent., of quartan[5] infections recorded by German observers in Palestine.

My thanks are due to the D.M.S. E.E.F., Major-General Sir R. Luce, K.C.M.G., C.B., A.M.S., and to the late Lieutenant-Colonel W. Angus, R.A.M.C., for permitting me to make use of information gathered in the course of my duties. I have to acknowledge my gratitude to my A.D.M.S., Lieutenant-Colonel J. J. Abraham, C.B.E., D.S.O., for his sympathy and encouragement in carrying out this scheme. I am indebted also to the officers in charge of military laboratories and diagnosis stations for permitting me to utilise their returns over the period under review; to my orderly, Private T. R. Goddard, R.A.M.C., who loyally assisted me during the last two years of the campaign; especially do I wish to thank my colleague, Captain E. C. Myott, R.A.M.C., for compiling the graphs which illustrate this report from statistics submitted to me weekly in the ordinary routine.

DIVERTICULITIS.

Being the Introductory Remarks to a Discussion at the Section of Surgery (Subsection of Proctology), Royal Society of Medicine, on Jan. 7th, 1920,

BY W. H. MAXWELL TELLING, M.D. LOND., F.R.C.P. LOND.,

CLINICAL LECTURER IN MEDICINE, UNIVERSITY OF LEEDS
HONORARY PHYSICIAN, LEEDS GENERAL INFIRMARY, ETC.

THE subject of diverticulitis is one in which the Subsection of Proctology has naturally a very special interest, but of which a full practical knowledge should be possessed by every abdominal, gynæcological, and genito-urinary surgeon, as well as by physicians and morbid anatomists. I will here concern myself with the broad lines of the subject, and mainly in its clinical aspects.

In 1917, when last reviewing the subject, I wrote[1]:—

> "Diverticulitis is a condition which has now passed out of the realm of doubt and uncertainty into that of proved and accepted fact. It has an important place in medical literature, and in the experience of every operating surgeon of large practice. This last statement is not as yet true of all clinicians, some of whom are still apparently unaware of the condition, and not a few of its frequency and clinical importance. Not until a morbid condition is described in all the ordinary student's text-books[2] of medicine and surgery can it be said to have attained complete recognition, and this is not yet the case with diverticulitis."

This is practically the situation to-day. Diverticulitis means any inflammatory change in any diverticulum or series of diverticula. In practice, however, usage has restricted the term to the inflammatory changes and secondary pathologic processes generally occurring in or in connexion with a certain type of diverticulum. This type is the secondary acquired, multiple, false diverticula of the *large* bowel, particularly and nearly always found in the sigmoid flexure. The diverticula occur mainly in the lower part of this structure in small or great numbers, but may be found elsewhere, as in the descending colon, the other flexures, the cæcum, the rectum, or throughout the entire large bowel. They may be limited to these special positions, though are more usually associated with sigmoid lesions as well; if so limited, they may give rise to puzzling and anomalous symptoms. The cæcal cases especially are of considerable interest, and merit much more attention and investigation than they have already received. Occasionally there is a widespread tendency to diverticulum-formation throughout the whole intestine. For convenience, however, I shall confine my remarks to the typical lesion as it occurs in the sigmoid flexure.

---

[5] The quartan parasite was found nine times out of 40,168 blood examinations by malaria diagnosis stations within six months.

[1] Brit. Jour. of Surgery, vol. iv., No. 17. To this article reference may be made for a detailed study with analysis of cases.

[2] A small paragraph first appeared in the 1910 edition of Osler's Medicine.

"*Stabilisation*" *of the Subject.*

Historically, diverticulitis may fairly be said to be a new subject. Odd specimens had been described from time to time during last century, but such descriptions were "buried" and isolated, and the clinical aspects of the lesion were for all practical purposes unknown. In 1898 Graser[3] described examples associated with fibrous hyperplasia, causing stenosing tumour-formation—*peri-diverticulitis.* Similar cases were then described in America, and Patel[4] in France drew particular attention to the more acute inflammatory lesions—sigmoiditis and peritonitis. I observed my first case in 1899 and finding nothing about it in the literature, or even any onewho was familiar with the condition, I thence onwards made it a practice to examine almost every sigmoid flexure personally at the autopsies I made. The result was the accumulation of a considerable amount of material. In 1907, Moynihan[5] published the first case in England of the Graser-tumour type, and this induced me to analyse and classify my cases. This I did in 1908,[6] and this was the first time the subject had been treated as a whole and the various pathological findings and clinical symptoms correlated, or that any complete arrangement and classification had been attempted. That classification has been in essentials accepted by almost all subsequent writers and observers, and writing now, 12 years later, when a very considerable number of cases has been observed and recorded, I have no important modification to offer.

The reason that this early "stabilisation" of the subject was possible is this: Given the occurrence of a tendency to the formation of multiple hernial out-pushings of the mucosa in the sigmoid flexure every secondary process that does in fact occur may be logically deduced a priori, by general pathological comparison and study. I am not proposing to deal with the vexed question of *why* these diverticula occur in the first place except that there is no doubt that they are largely, if not entirely, due to increased pressure from within the bowel. Constipation, therefore, plays an important part, but I feel convinced that flatulent distension, often co-existing, of course, has a rôle that cannot be overlooked and needs more study.

Anatomy of the Diverticula.

A knowledge of the anatomy of these diverticula is of the first importance in understanding the secondary pathologic processes, and also in detecting them at all, either in the dead-house or at operation. At this point the inquiry is pertinent as to how it comes about that the condition has for so long escaped practical recognition, having regard to the large number of cases recorded—not a tithe of those observed—since 1898. The answer, is, I think, to be found in three facts. Firstly, the majority of demonstrators of morbid anatomy fail to devote special and personal attention to the sigmoid flexure, and perhaps to those surgical autopsies in which the surgeon has "spoiled" the abdomen generally and a specimen in particular by his manipulations; particularly when the structures operated on have been more or less inflamed, adherent, and "mixed-up." Secondly, the diverticula themselves are "adepts" at concealment; this I will return to later. Thirdly, the secondary pathologic processes are liable to be so extensive and disproportionate to the comparatively insignificant diverticula as to hide the true nature of the case from any but patient and skilled observers. This must be the general experience of all who have studied a series of specimens in situ.

The second of these points, the "self-concealment," turns upon the anatomy of the diverticula. Firstly, they are small, varying from minuteness up to the size of the last joint of the little finger; more commonly they are 1/3 to 1/5 this size. Their apertures are often minute, from 1/16 to 1/3 of an inch in diameter, and these apertures usually occur in two rows, mostly opposite the appendices epiploicæ, and often completely concealed by the rugose mucous membrane. On the outside of the gut the diverticula are seldom observed, except by the trained eye, because: (1) they mainly enter the appendices epiploicæ as stated; and (2) the gut in which they occur is very frequently fat-laden, necessitating careful dissection to discover them at all. The occurrence of adhesion to other structures and of peri-diverticular hyperplasia tends still further to conceal and almost to obliterate their presence. Even so, the fact that isolated observations on them for over a century should have failed to lead to complete recognition is a little remarkable, but none the less a fact.

I am stressing these anatomical points rather carefully, as they must be fully appreciated by every operating surgeon if he hopes to recognise the condition at the time of the operation.

Once the diverticula are "in being" the whole series of possible consequences depends upon the following three facts: (1) being formed by pressure from within they tend to enlarge; (2) they tend to harbour fæcal or other harmful contents; and (3) as a consequence they tend to undergo various secondary pathologic processes. In their enlargement they become flask-shaped, with a bottle-neck; this bottle-neck may greatly elongate, its lumen remaining very narrow. This elongation is brought about by *peri-diverticular hyperplasia*, which often pushes the "flask" to its circumference, where it "sits" on the surface of the tumour and works special mischief of other kinds, such as adhesion, perforation, and fistulous communication.

Secondary Processes.

The narrow mouths tend to promote the retention of fæcal contents, soft or forming actual concretions. Here analogy with appendicitis will largely help us to prophesy results, except in regard to the remarkable hyperplastic peridiverticulitis. The fæcal contents form a bacterial nidus, a reservoir of toxins and a source of mechanical irritation. As a result secondary changes supervene; if not, the condition remains a harmless pathological curiosity and gives rise to no symptoms or trouble. Perhaps the large majority of instances are largely or entirely innocuous.

---

[3] Cent. f. Chir., 1898.

[4] Lyon Chir., 1911, vi.

[5] Edin. Med. Jour., 1907, xxi., p. 228.

[6] THE LANCET, 1908, i., 843.

The main secondary processes which do occur, separately or variously combined, are: (1) Ulceration of the mucosa of the diverticula. (2) Perforation as a consequence. (3) Adhesion to other structures which, when combined with (2), leads to fistulous communication. (4) Peridiverticular fibrous hyperplasia leading to tumour-formation and, as a sequential result, stenosis of the bowel.

Confining our attention to these main and usually secondary processes, which, as has been stated, may be variously combined, a few moments' consideration will show how protean and puzzling the resulting clinical manifestations may be. In the first place, mucosal ulceration will weaken the wall of the sac. This will facilitate perforation, and a concretion will be specially liable to be driven through at any time of increased pressure or violent effort, causing a local or general peritonitis. In quite a number of cases this has actually happened.

The mucosal ulceration also sets up inflammation on the outer surface of the diverticulum leading to adhesions. These *may* produce no important results, but *may* produce vesical or pelvic syndromes or an acute intestinal obstruction by band or kink. Adhesions plus perforation lead either to local abscess with its varied symptoms, signs, and sequential risks and possibilities, or to fistulous communication with other viscera, of which that with the bladder is the commonest, most interesting, and surgically the most important instance.

Peridiverticular Hyperplasia.

The culminating interest is reached, however, in the production of the fourth type of lesion, the peridiverticular hyperplasia. This may exist with mucosal ulcerations of the diverticulum, but not infrequently occurs without it, and is a common and characteristic result, the one which first led to a systematic investigation. It is undoubtedly due to a chronic leakage of toxins or bacteria, or both, through the sac walls, producing a hyperplastic fibrous-tissue formation somewhat similar to that found in hyperplastic tuberculosis of the cæcum, or more closely resembling a scirrhous cancer. Because of the hyperplasia, which may amount to an inch or more in thickness on section, a tumour is produced; because it is fibrous the tumour contracts and stenoses the bowel, tending towards chronic intestinal obstruction. This thickening and stenosis may be so local as to make an annular stricture, and it will be realised how close is the mimicry of carcinoma. In this way, doubtless, many of the cases of so-called "cured" cancer in this region may be explained, as well as the placing on museum shelves examples of peridiverticulitis labelled cancer. Others besides myself have found them.

There is, however, a very special relationship of the condition to true carcinoma. A simple peridiverticular stenosis (or possibly other diverticular lesion) may develop carcinoma secondarily, as in the case of a chronic gastric ulcer. A small number of cases have now been put on record, and since my last records were published in 1917 I have had a further case. The patient was riding and felt a sudden pain in the left iliac fossa, followed by temperature and signs of inflammation. I made a diagnosis of perforative diverticulitis, and Sir Berkeley Moynihan operated and confirmed, finding multiple diverticula, one of which had perforated and set up general peritonitis. There was also some thickening and stenosis, but no naked-eye evidence of malignancy. A year later a second surgical inspection was made, and malignant disease was then obvious and inoperable.

It is not too much to say, therefore, that no surgeon ought to decide about or operate on a supposed carcinoma of the sigmoid flexure without an accurate knowledge of what may be termed "diverticular possibilities," nor ought any such tumour removed by operation to lack a complete and *skilled* examination for the presence of a diverticula. It was only by this means that Moynihan detected and recorded the first of such cases in the English literature.

Groups of Secondary Processes.

We can usefully divide the secondary processes into two such groups: (*a*) mechanical (mainly), and (*b*) inflammatory (mainly). Both processes may go on in the same case, just as there may be present together varying types of inflammatory reaction.

A. *Mechanical.*

1. Formation of fæcal concretions in the diverticula.
2. Torsion of the diverticulum.
3. Lodgment of foreign bodies within the diverticular sacs.
4. Perforation.

B. *Inflammatory.*

1. Diverticulitis: (*a*) Gangrenous; (*b*) acute; (*c*) subacute; (*d*) chronic; (*e*) latent.
2. Passage of organisms without perforation.
3. Peridiverticulitis—chronic proliferative inflammation with tendency to stenosis of the bowel.
4. Perforation of the diverticula, giving rise in particular to: (*a*) General peritonitis; (*b*) local abscess; (*c*) fistula, especially into the bladder; (*d*) suppuration in a hernial sac.
5. The formation of adhesions, especially to: (*a*) The small intestine; (*b*) the bladder; (*c*) the female genitalia.
6. Chronic peritonitis, local.
7. Chronic mesenteritis of the sigmoid loop.
8. Metastatic suppuration.
9. The secondary development of carcinoma.

By the aid of this pathological series it is not difficult to forecast the main clinical symptoms and also to surmise that they will be liable to be variable, complex, and puzzling. This is so in fact, as a study of case records abundantly proves. At the same time, the majority of cases conform more or less to the following types: (1) Inflammatory trouble or tumour in the left lower quadrant of the abdomen; (2) general peritonitis; (3) vesicocolic fistula; (4) pelvic syndromes; (5) intestinal obstruction; (6) mimicry of carcinoma.

The frequency of tumour or abscess formation in association with any or all of these is considerable (about 30 per cent.), and one may say that any case from the age of 30 onwards, presenting these symptoms, calls for a mental reservation as to the possibility of a diverticular origin, and in some instances the diagnosis can and has been made with certainty and accuracy.

As general clinical points it must be remembered that cases occur mostly at or after middle age (though a few cases in early life have been noted)—in males more frequently than females; usually with a history of constipation and very seldom causing blood in the stools. A few comments are called for on some of the foregoing clinical types of case.

Inflammatory trouble, more or less acute, in the left lower quadrant of the abdomen.—Cases of this type constitute by far the largest group. Erdmann has gone so far as to say that the occurrence of left-sided pain, with mass or not, but with tenderness and rigidity, is practically pathognomonic of diverticulitis. This is the extreme view, favoured by the main supporters of the almost exclusive rôle of diverticula in inflammatory troubles in this quarter. Fitz in 1912 said that the cases comprised in this "inflammatory" group made a fairly complete picture of what must be recognised as a new disease of the lower abdomen—diverticulitis of the left quadrant, analogous to appendicitis of the right quadrant. Bladder and pelvic symptoms are not uncommon.

Various sub-types of the inflammatory group may be distinguished, and a useful clinical classification is as follows:—

1. *Acute and fulminant* (gangrenous).—Symptoms practically identical with acute right-sided appendicitis.
2. *Recurrent.*—Acute or subacute attacks over a long period.
3. Cases ending in *spontaneous recovery.*

Protracted cases.—Those which continue till the clinical picture is changed by one or other of the following developments: (*a*) Simulation of carcinoma; (*b*) intestinal obstruction (acute or chronic); (*c*) bladder perforation; (*d*) general peritonitis; (*e*) incidence of pelvic symptoms.

Trauma.—The mode of onset of many of the acute cases is of interest as showing the great part which trauma of various kinds may play. It has a definite diagnostic value when diverticulitis is under suspicion, and acts as an exciting cause of, at any rate, the acute manifestations. These have occurred straining at stool; during the administration of an enema; following a dose of castor oil; jolting in a motor-car; following a heavy meal; while lifting a weight, jumping, or hunting; while at work; and during an abdominal operation.

In this group pain of one kind or another (often recurrent and colicky) and tenderness are very frequent. Tumour-formation has been noted in 30 per cent. of the cases, and the tumour is not infrequently and then characteristically variable. Abscess-formation is very frequent, consequently fever and leucocytosis are often present. Bladder and pelvic symptoms are not uncommon. Apart from actual fistulous communication with the bladder, which constitutes a separate clinical group, there are frequently symptoms of bladder irritability, probably due to the nearness of inflammatory foci or to actual adhesion. Pelvic symptoms are of some frequency and sometimes make the clinical picture.

Vesico-colic fistula and bladder symptoms generally. In a recent review[7] Bryan has stated that "diverticulitis" is the most frequent cause of sigmo-vesical fistula. Moynihan was the first observer in England to emphasise this fact. He wrote in 1907:—

> "The formation of a vesico-intestinal fistula seems to be one of the tendencies of a perforated false diverticulum; a search through the literature has shown that it is far more common than was supposed. In cases where a hard growth in the intestine is accompanied by the passage of flatus and fæces by the urethra, a diagnosis of carcinoma seems irresistible, yet the *probability* is that 'the growth' would be simple, and that the cause of the fistula would be a false diverticulum which had burrowed its way through all the coats of the bowel, and thence through the wall of the bladder, which had become adherent."

Experience has abundantly confirmed the truth of this statement, and its recognition has been followed by some brilliantly successful cases at Leeds, cured by operation after long periods of suffering.

Pelvic syndromes.—Much has been written in recent years about the close pathologic relationship between the sigmoid flexure and the other pelvic viscera. Much of it has been without any or a very extensive knowledge of the rôle of the diverticulum. It is not surprising to find diverticulitis increasingly frequent in the practice of gynæcological surgeons. Pelvic symptoms of one kind or another existed in 7 per cent. of my collected cases, and a number of examples have been placed on record in which the symptoms were entirely pelvic, bowel symptoms being absent. There is no doubt that Shoemaker[8] strikes the right note in saying that in any suspected case of pelvic or utero-ovarian disease a routine and thorough examination of the recto-sigmoidal bowel and its functions is just as important as a vaginal and uterine examination.

Diagnosis.

This can only be made after a careful consideration of all the facts of the case. Inflammatory trouble in the left lower quadrant in a person of middle or advanced age carries with it a strong *prima-facie* possibility of a diverticulitis being the cause, but beyond this exact diagnosis is often difficult, and all special aids to diagnosis may have to be requisitioned. These include (1) the sigmoidoscope, which has been disappointing in the main in this condition, though perhaps some members may have had more fortunate experience; (2) the cystoscope, which has been of particular value in a small number of cases; and (3) examination by X rays. This last procedure holds out most promise, and has been greatly developed during the last few years. As may be expected, the technique is not of the easiest, and there are many fallacies in the appearances noted, but there is no doubt of the general diagnostic value.

The outstanding condition calling for differential diagnosis is carcinoma. It may be, and often is, impossible, not only before operation, but at operation. The following summary of the chief points differentiating diverticulitis from carcinoma may be of use.

1. The absence of the "shadows of malignancy" from the general picture.
2. Tendency to obesity and maintenance of good nutrition generally.
3. Long history of attacks of abdominal pain in the left lower quadrant.
4. History of tumour-formation with subsequent disappearance.
5. Absence of blood (visible to the naked eye) in stools over a prolonged period.
6. Presence of a vesical fistula, in which malignancy can be excluded by cystoscopy.
7. Negative sigmoidoscopy as regards malignant disease.
8. X ray demonstration of diverticula.
9. Pyrexial attacks.
10. Examination of blood, the presence of neutrophilic leucocytosis, and the absence of the specific nuclear changes characteristic of cancer.

---

[7] Ann. Surg., 1916, lxiii., 353.

[8] Ann. Surg., 1914, lix., 422.

In carcinoma of the sigmoid loss of flesh is early, pain and tenderness are late, and are often preceded by tumour.

There are certain other conditions which have to be considered in arriving at a differential diagnosis. They are: (*a*) sigmoiditis; (*b*) hyperplastic tuberculosis; (*c*) actinomycosis; (*d*) syphilis; (*e*) pelvic conditions generally.

Treatment.

This is comprised in a single word—surgery—unless operative interference is specially contraindicated. As a physician I shall not venture to discuss particular surgical procedure, but confine myself to a few general points.

In view of the potentiality for mischief of diverticula, all diverticulum-bearing gut should be removed. At operation, search should be made, whenever possible, for further diverticula. Recurrence after operation has occurred, presumably from neglect of this point. There seems to be a special liability to post-operative peritonitis, possibly due to the chronic infection of the inflamed tissues in some cases.

Care should be taken in handling the gut, as at least one instance has occurred of rupture of a diverticulum by surgical traumatism. The good results already obtained in certain bladder fistulæ should stimulate surgeons to deal with such cases. In at least one very successful case the possibility of successful intervention had been negatived by several surgeons of eminence.

Lastly, no case of supposed carcinoma of the lower bowel must in future be regarded as inoperable, either before or at laparotomy, unless diverticulitis has been remembered, fully considered, and systematically investigated.

Leeds.

A SUGGESTED SCALE FOR
FEEDING INFANTS ON DRIED MILK.

BY VYNNE BORLAND, M.B., CH.B., B.SC. GLASG., D.P.H. LOND.,
ASSISTANT MEDICAL OFFICER OF HEALTH, WILLESDEN URBAN DISTRICT COUNCIL.

IT is now generally recognised that many diseases of early childhood, and in some cases of later life, are due to over-feeding at an early age. This refers more particularly to babies artificially fed than to breast-fed babies, and since in later years dried milks have come very much into use for baby feeding there is a greater tendency towards over-feeding.

While attending the consultations at an infant welfare centre one is soon struck by the great differences in weight of babies of a similar age. If they are bottle fed one finds, with very few exceptions, that, although there may be as much as 3 lb. or 4 lb. difference between their weights at the same age, they are receiving practically the same quantity of milk in 24 hours. The reason for this is that feeds are given according to the age of the child, the weight being considered only in a haphazard way. This occurs more particularly in those cases that are fed on the various "baby foods and dried milks" which bear the instructions for feeding on the covering label. This matter becomes more important under the present difficult conditions when, owing to the decreased value of money, a large number of nursing mothers go out to work in order to lessen their financial troubles, and consequently their babies are no longer breast fed. At the same time, owing to the scarcity of fresh cows' milk, the demand for specially prepared milks has very materially increased, and many local authorities have adopted "dried milks" as the most convenient form of distribution in connexion with a welfare clinic, either at cost price or free in necessitous cases.

A Plan for Feeding Babies in Accordance with their Weight.

Taking these facts into consideration, it is desirable that a more appropriate method of arriving at the necessary feeds should be adopted than by calculating quantities of feeds according to age alone. Therefore it is suggested here that it would be an infinitely better plan to feed a baby in relation to its weight. This method has produced very satisfactory results in Willesden, where it has now been practised for over two years. It might be argued that regular weighing is difficult, but in view of the increasing number of infant welfare centres throughout the country this difficulty vanishes. The middle and upper classes generally have scales at home, or they can have their babies weighed at a chemist's shop.

It is not intended to discuss here the advantages or disadvantages of dried milk for infant feeding, as that has been fully dealt with elsewhere,[1] but only to endeavour to present a scale of feeds that may prove of use to such local authorities or others who adopt this form of milk distribution. The present scale is based chiefly on a full-cream dried milk which has been modified to resemble human milk, but others not so modified have answered satisfactorily when given according to scale.

If the suggested scale of feeds is to be adopted it is essential that it should fulfil the following conditions: 1. It must be practicable. 2. It must be easily understood by doctors, nurses, mothers, or any person having charge of the baby. 3. The calculated amount of feed must produce a satisfactory gain in weight per week. 4. The stools must remain normal.

The investigation was carried out primarily on 69 babies of ages ranging from 3 weeks to 8½ months and weights ranging from 6 lb. 7½ oz. to 21 lb. 1¾ oz. The smallest feed which produced a satisfactory gain, the baby otherwise being in good health, was chosen from the clinic cards and noted. In this way 188 feeds at various weights were obtained. These were arranged in successive increasing weights and an endeavour made to produce a simple formula that could be used for guidance.

It has been the practice of the writer to arrange breast-feeding at intervals of 3 hours, 3½ hours, and 4 hours, according to the age of the child and the progress made. The 4-hourly intervals are begun as early as possible. In the case of the 3-hourly intervals the number of feeds given in the 24 hours is six, in 3½-hourly intervals five feeds, and in 4-hourly intervals five feeds. It has been remarked that in a large number of cases fed every 4 hours four feeds in the 24 hours produce satisfactory results. Accordingly, when a baby is artificially fed this principle is adhered to and only four bottle feeds are given in the 24 hours.

A Formula for Babies' Feeds.

After trying several means of obtaining a suitable formula it was found that by adding the number 9 to the weight if below 7 lb. and the number 10 to the weight from 7 to 16 lb. inclusive the required number of level teaspoonfuls of dried milk to be given in 24 hours was obtained. From 17 lb. upwards when the child is having four feeds in the 24 hours the second figure of the number of pounds' weight is taken as one feed. For example, if the weight is 17 lb. then four feeds are given each containing seven level teaspoonfuls of dried milk. It might just be mentioned at this point that all the various "full-cream dried milks" are reconstituted by a dilution of 1 in 8—i.e., one level teaspoonful to an ounce of water.

---

[1] Report to the Local Government Board. By F. J. Coutts, M.D., B.Sc., D.P.H. (Food Reports No. 24.)

This formula will then be as shown:—

Below 7 lb. add 9 to weight = up to 16 level teaspoons in 24 hours.

From 7 to 16 lb. add 10 to weight = 17 to 26 level teaspoons in 24 hours.

From 17 lb. upwards take second figure as one feed = 28 teaspoons upwards.

Table I. shows how the formula works out in practice. The formula was applied to obtain the required feeds of 47 babies attending the clinic for the first time and which were already being fed on full-cream dried milk, but without proper regulation of feeding.

TABLE I.

Age.	Weight in lb., oz.	No. of teaspoons per feed.	No. of feeds.	Intervals in hours.	Total in 24 hours.	Gain.
7 wks.	6 2½	2½, 2½, 2½, 2½, 3, 3	6	3	16	8¼ oz. in 7 days.
4 ,,	6 8½	2½, 2½, 2½, 2½, 3, 3	6	3	16	2 ,, ,,
5 ,,	10 0	4, 4, 4, 4, 4	5	3½	20	4¼ ,, ,,
5 mths.	12 11½	5½, 5½, 5½, 5½	4	4	22	5 ,, ,,
8 ,,	18 9	8½, 8½, 8½, 8½	4	4	34	6½ ,, ,,

Another series represents the feeds of 25 babies, calculated according to formula, that were started on full-cream dried milk for the first time. In practically every case a satisfactory gain in weight was procured.

It will probably be argued that there is no guarantee that only the prescribed number of feeds with the proper quantity are given by the mother. In answer to this one may say that the dried milk is strictly rationed and the mother given very definite instructions that she must on no account exceed the quantity prescribed. Also it may be stated that the large majority are necessitous cases, receiving their supply free of charge, and they are informed exactly how long their supply should last. With very few exceptions the supply lasts until the day they are due to receive a fresh lot.

With the increasing scarcity of milk it has become the practice of the writer not to give any more than 30 level teaspoons per day save in exceptional cases. That is to say, when a baby weighs 17½ lb. it receives four feeds per day, each containing 7½ level teaspoonfuls of dried milk. This, when reconstituted, amounts to about 1½ pints. At this point small quantities of fine milk pudding are added, and the results are very satisfactory.

Table II. has been drawn up to show how the feeds may be given according to the formula. It will be noticed that the feeds only rise up to 7 teaspoonfuls given four times, but it must be left to discretion as to whether one ought to give more than 7½ teaspoonfuls four times—equal to about 1½ pints—when the child can assimilate small quantities of milk pudding. It is an established fact that the power of assimilation of infants is very variable, and, accordingly, one cannot say dogmatically that a child of a given weight should only require a certain quantity of milk in 24 hours. But if a child weighs so many pounds, then by giving a certain minimum quantity we can gauge to a great extent the assimilative power of that child and regulate the feeds accordingly.

TABLE II.—*Arrangement of Feeds According to Formula.*

Weight in lb., oz.	No. of level teaspoons per feed.	No. of feeds.	Interval in hours.	Total in 24 hours.
6 8	2½, 2½, 2½, 2½, 2½, 3	6	3	15½
8 0	3, 3, 3, 3, 3, 3	6	3	18
11 8	4½, 4½, 4½, 4, 4	5	3½	21½
15 0	6½, 6½, 6, 6	4	4	25
17 0	7, 7, 7, 7	4	4	28
17 8	Same plus ½ teaspoon pudding one feed.	4	4	28
18 0	Plus ½ teaspoon pudding two feeds.	4	4	28
18 8	Plus ½ teaspoon pudding or porridge three feeds.	4	4	28
19 0	Plus pudding or porridge four feeds.	4	4	28

The formula given above is not only useful as a starting-point, but can be used for guidance from week to week. A feeding programme can be given for as long as four weeks, so that the mother need not come to the clinic unless something happens to the child in the interval. This is arranged by giving each week one ½ teaspoonful more to the total quantity per day—i.e., one feed is increased by one ½ teaspoonful each week.

A SIMPLE MEANS OF LESSENING OR ELIMINATING

ALIMENTARY TOXÆMIA.

BY R. CHETHAM-STRODE, M.B., C.M. EDIN.;
AND
J. D. BENJAFIELD, M.D., B.S. LOND., M.R.C.S., L.R.C.P.,
BACTERIOLOGIST, KENSINGTON GENERAL AND WESTERN SKIN HOSPITALS.

THE important part played by an alimentary toxæmia in the causation and aggravation of disease is now generally accepted by the medical profession as a whole. The large intestine has been credited in the past as the chief offender in this respect, and many attempts, both medical and surgical, have been made to reduce its power of formation and capacity for absorption of toxins. Sir Arbuthnot Lane has adopted his operation of short-circuiting, a heroic measure to say the least of it, and one not invariably attended by corresponding benefit on behalf of the patient. Metchnikoff and his school have drawn attention to the longevity of certain races of mankind in whom the only common factor was the consumption of some sour-milk product. He therefore assumed that such products, whose active constituent is known to be lactic acid, would produce correspondingly beneficial results in other races.

Assuming, then, that a lactic-acid fermentation in the large intestine is the condition to be aimed at, the problem reduces itself to one of simple chemistry. We know that lactic acid is produced in milk by the fermentation of the lactose by bacteria. We have in the large intestine numerous bacteria capable of effecting this. We have, therefore, to find some means of supplying the necessary lactose. Carbohydrates administered by the mouth in the usual easily digestible form will not supply this ingredient, as they are broken up and absorbed during their passage through the stomach and small intestine. Thus the carbohydrate must be supplied in some form in which it can resist the action in part, at least, of the gastro-intestinal ferments.

The simplest means of overcoming this difficulty, and the one adopted by us in our practice, is to administer the carbohydrates in the form of coarse uncrushed oatmeal. This may be taken raw or cooked sufficiently to soften the outside of the grain, only leaving behind a hard core. The result is that the partially digested grain reaches the large intestine in the form of carbohydrate. The centre of the grain is composed of unaltered starch, whilst the outer layers, which have been subjected to the digestive action of the juices of the mouth, stomach, and small intestine, are composed of simpler molecules, the disaccharides, and hexoses. Both these latter can be rapidly converted into lactic acid and CO_2 by a suitable bacterial flora.

The fæces of the average individual are neutral or alkaline to litmus, and from what we have already said it would appear that the production of a lactic-acid fermentation was quite a simple matter. This takes place in many cases, more especially when dealing with the young, but there remain quite a large number of individuals whose excreta do not at all readily become acid. It is with this group of cases that we must deal in some detail, as they are the ones that concern us most closely, and we must apply ourselves to the discovery, if possible, of some preventive factor. The causes which may prevent the acid fermentation may be grouped under the following headings: (1) Stasis; (2) presence of unsuitable organisms in the fæcal flora; (3) absence of essential organisms from the fæcal flora; (4) an unsuitable dietary.

1. *Stasis.*

On examining Gram-stained films of the fæces of individuals who are more or less constipated one finds the following bacterial elements: (*a*) Gram-negative bacilli of coliform group; (*b*) Gram-positive cocci and diplococci and short chains of streptococci; (*c*) Gram-positive and Gram-negative bacilli containing spores; (*d*) Gram-positive coarse bacilli without spores (Bulgarian group). In a case where stasis is marked those classified under (*a*), (*b*), and (*c*) will all be present in fæcal films in large numbers, whilst (*d*) will only be found after some search. On the other hand, films from a case where stasis is absent will show a very different picture—that is, complete absence of spore-bearing bacilli, very few streptococci, a large number of bacilli of the Bulgarian group, and the remainder coliform organisms. Another difference between the two microscopic preparations will be seen; in the first the definition of the organisms will be poor and the stain taken up irregularly, whilst in the second specimen the converse will be the case. However, the most marked difference between the two specimens is to be found in the relative proportion of the Bulgarian to the coliform organisms. In the first case they may be in the proportion of 1–250 coli, whilst in the second case they may constitute a much higher ratio—e.g., 1–5. Thus this ratio, which one may legitimately term the "Bulgar Index," can be accepted as an indication of the presence or otherwise of intestinal stasis.

On abdominal examination of cases in this group one will probably find that there is some enteroptosis of the transverse colon, and on percussion of the gut in the neighbourhood of the cæcum dullness may be elicited. In such a case deep abdominal massage may be the determining factor in producing lactic-acid fermentation. This we consider to be a very powerful adjuvant in procuring the required result, for not only does it act by causing the contraction of the muscular walls of the gut, and the consequent propulsion of the contents, but also by improving the blood-supply of the gut wall it increases the secretions into the lumen. It is also essential that the oatmeal should reach the large intestine without too much delay; for this purpose again the abdominal massage is most useful.

Aperients may also be required. We find aloin is generally most useful. Calomel may be used occasionally, but should not be given too frequently as it appears impossible to maintain a lactic fermentation if any mercury is being administered. Liquid paraffin is also contra-indicated, as it again prevents this fermentation from taking place, possibly by forming a film-coating over the oat grains, and so preventing their interaction with the necessary bacteria.

In long-standing cases of stasis matters may be somewhat accelerated by washing out the large intestine at the commencement of treatment. The possibility of stasis must not be overlooked in a patient who gives a negative history as regards constipation, for on examination these may prove to be well-marked cases in whom the daily action is to be regarded merely as being an overflow from an already full cesspool.

2. *Presence of Unsuitable Organisms.*

Should a case resist the above measures, it will next be necessary to plate out the fæces on some differentiating medium. MacConkey's neutral red-bile salt-peptone-lactose-agar we have found to be the most generally used for this purpose. A thorough search for any non-lactose fermenters should be made, and in an obstinate case the examination should be repeated on several occasions before definitely excluding their presence. Should any non-lactose fermenters of the coliform group be present, a vaccine of this organism should be administered, for, from experience, it appears that the presence of a very small proportion of organisms of this class are fatal to the production of the desired fermentation. Usually after a few doses of an autogenous vaccine the invader disappears and the patient's stools become acid.

The organisms of this type most frequently encountered give the following sugar reactions: lactose, 0; glucose and mannite, acid and gas; dulcite and saccharose, 0. For the sake of convenience we call them enteritidis group; they do not usually agglutinate with the patient's own blood serum, nor with any of the high-titre sera of the paratyphoid group.

Other organisms met with which are apparently equally capable of preventing the desired result are *B. coli mutabile*, *B. fæcalis alcaligenes*, *B. proteus*, and, more rarely still, organisms of the dysentery group. Other cases may prove to have a large excess of *Streptococcus fæcalis*, which again may inhibit the desired reaction. Thus it is advisable to conduct fæcal examinations from the commencement, for not only do they assist one in diagnosis and prognosis, but a sure guide of the patient's progress may be obtained from the "Bulgar Index." Also much valuable time may be saved by the discovery at any early stage of a non-lactose fermenter.

3. *Absence of Essential Organisms from Fæcal Flora.*

This class of case may be recognised by the failure to produce acid fermentation, in spite of the fact that severe stasis has already been relieved, and by the failure to isolate non-lactose fermenters from the stool. In such instances the fæcal films do not show a good "Bulgar Index," but the proportion of the Bulgar group to the coliform organisms remains about 1–40. These require a sour-milk preparation which is rich in the required organisms.

4. *Unsuitable Dietary.*

For reasons not well understood there are some articles of diet which effectually prevent a lactic-acid reaction being maintained. The most notable of these are whisky, asparagus, pears, and salmon. After all the measures already detailed have been tried there will still remain a small residue of cases in whom one cannot produce an acid fermentation and who are not materially benefited by the treatment. For this reason it is obvious that the possible criticism that the beneficial results of the treatment are due merely to the amount of purging the patient is subjected to, cannot stand. The presence of the lactic-acid fermentation appears to be an essential one, and once this is obtained the rapid results achieved are almost incredible. Possibly the explanation is merely one of improved drainage—that is, the large intestine becomes much less tolerant to an acid content and therefore is in a constant state of peristalsis.

We are of opinion that this is not the sole explanation, for were it so one would expect much more frequent evacuations of the bowel, whereas in actual practice two, or at least three evacuations in the 24 hours are all that are necessary for the maintenance of the acid reaction. The facts that the offensive odour of the stool is rapidly lost on attaining the lactic-acid fermentation, and that the ordinary products of putrefaction (indol and skatol, &c.) are rapidly reduced in quantity, render it probable that the lactic acid actually exerts an antiseptic action on the organisms concerned in these processes.

One of us (R. C.-S.) has been combining this course of treatment with the ordinary symptomatic methods in his medical practice for the last 15 years. During this period the treatment has become more elaborated, and some of its difficulties realised and overcome. Failures have been met with, but they have all been failures in that the lactic-acid fermentation could not be obtained. In all cases where this fermentation has been established the condition of the patient has been materially improved. We select the notes of a few typical successful cases.

Typical Cases.

CASE 1.—Mrs. C., aged 48. Rheumatoid arthritis. Disease commenced in 1905 in wrist-joint, spreading later to the small joints of hands and feet. First seen in 1908 when the disease was well advanced; there were typical swelling and deformity of small joints of hands and feet and wrist, the knees also were commencing to become involved. The treatment was continued for 12 months and considerable benefit was derived, pain being much diminished and the progress of the disease being temporarily arrested. Treatment was then discontinued until 1913, and the patient once more became bedridden owing to deformity and pain of the knee-joints. A lactic-acid fermentation was once more established in July, 1913, and maintained with rare remissions until March, 1914, when she could walk with comparative ease and comfort. Since this time she has been able to perform all her housework. The treatment was discontinued two years ago, and it is only at the present time that the disease shows signs of renewed activity.

Note.—In this case treatment was not commenced until late when bony deformity was marked, but, in spite of this, progress has been completely arrested.

CASE 2.—Mrs. W., aged 57. Severe neurasthenia. Seen first in 1912, when headaches, insomnia, loss of memory, and palpitation were marked. At this time she also suffered from attacks of semi-collapse which lasted for 24 hours or more, when she would remain in a lethargic state. These attacks had been getting more frequent and occurred every four or five days; during them she appeared bloated and repulsive-looking, and to her friends had the aspect of a drunkard. She had no wish to live. On examination her heart was found to be dilated, cardiac dullness extending to one inch outside the mid-clavicular line; mental dullness and apathy were marked. Dullness over the cæcum was present, and the transverse colon had dropped to the brim of the pelvis. A lactic-acid fermentation was established in the large gut after three weeks' treatment and was at first maintained with considerable difficulty. Improvement commenced after a month's treatment and was at first manifested by a lengthening of the interval between the attacks. After 12 months she had regained her normal health and has since remained quite well.

CASE 3.—Mrs. H. J., aged 42. Ulcerative colitis. First seen in 1910. Illness commenced in 1905, and for the following five years she suffered from intermittent attacks of general abdominal pain, which had no relation to the taking of food. The pain was so severe that at times morphine had to be administered. She was habitually constipated, though attacks of diarrhœa occurred not infrequently. Blood and mucus was commonly passed during these attacks. She also suffered from severe attacks of depression and palpitation. Treatment commenced in May, 1910. Lactic-acid fermentation was easily established by means of oatmeal and massage. Symptoms rapidly cleared up, and the patient has shown no signs of any relapse.

CASE 4.—A. G., aged 17. Asthma. The patient had suffered from asthmatic attacks since a baby of six months. The attacks were characterised by a difficulty in breathing and "stuffiness" of the upper air-passages. At the end of 1916 he was having severe attacks of typical asthma, lasting about three days once a fortnight; during the attacks he was very breathless, having to sit up and fight for breath. There was no sputum. These attacks were commonly brought on by indigestion or head cold, the former being a very troublesome symptom throughout. His tonsils and adenoids were removed in 1912, after which there was a considerable improvement for a year. Commenced treatment in January, 1917. A lactic-acid fermentation in the large intestine was easily established by means of abdominal massage, oats, and aloin; improvement was very rapid, no definite attack of asthma since February, 1917. He is now able to eat anything, plays football, cricket, &c., and has not lost a day from work or school since that time.

CASE 5.—J. M., aged 42. Severe toxæmia presenting clinical picture of neurasthenia. Chief symptoms, headache, sleeplessness, palpitation, and loss of memory. History of two years' illness. On examination he was found to have a marked anæmia and some cardiac enlargement; no physical signs in the nervous system. Practically no improvement followed early efforts in treatment, and a lactic-acid fermentation could not be established. Three fæcal specimens had been examined without the isolation of any non-lactose fermenters. The plate of the fourth specimen showed 50 per cent.

colonies of an organism of "Enteritidis" group. An autogenous vaccine was administered. Five weeks later a lactic-acid fermentation was established, and the patient rapidly recovered normal health.

From the above rather dogmatic statements it may perhaps be thought that we advise this line of treatment as a "panacea of all ills," but this is not the case. What we do maintain is that a lactic-acid fermentation in the large intestine is a most desirable possession, both in health and disease, and that if it can be produced in the latter so much the better. We are not advocating that all other symptomatic or specific treatment should give way to the suggestions we have made, but we do think that, wherever possible, they should be combined with it.

THE PARATYPHOID B GROUP.

BY HARRY SCHÜTZE, M.B., B.S.MELB., M.D.WÜRZ.,
BACTERIOLOGIST, LISTER INSTITUTE.

SINCE Bainbridge and his collaborators in 1911 declared that it was possible by means of the absorption test to differentiate between Aertrycke and paratyphoid B organisms, various workers have attempted to prove the invalidity of the differentiation, while others have advocated the use of certain cultural tests to supplement the serological characterisation of the two groups.

During the examination of a number of strains the present writer has come to the conclusion that not only, as is becoming universally recognised, is it possible to differentiate, by the investigation of their respective absorptive characters, an Aertrycke bacillus from a paratyphoid B, but to subdivide, by means of the same test, the Aertrycke organisms into a number of types.

Fallacies in Classification by Clinical and Cultural Methods.

There are three main biological features which might be of use in the classification of paratyphoid B–Aertrycke members of the Salmonella group—their clinical manifestations, their cultural characters, and their serological characters. The clinical manifestation is not to be accepted as a guide to the nature of the causative organism in every case, and it is doubtless the failure to recognise this fact which has influenced Uhlenhuth in deciding that Aertrycke and paratyphoid B organisms are identical.

Bainbridge and Dudfield[1] have published a case of acute gastro-enteritis due to what was serologically paratyphosus B, while this paper will bring evidence of illness of an enteric nature presumably due to an organism which must undoubtedly be placed, according to the agglutination and absorption tests, among the "Aertryckes." Uhlenhuth,[2] it will be remembered, started out with a number of strains labelled paratyphoid B, suipestifer, food-poisoning bacteria, psittacosis, &c., and proceeded to show that some suipestifers remove paratyphoid B agglutinins from paratyphoid B serum, while some paratyphoid B strains do not. It is clear, then, that two groups of organisms, one absorbing and the other not absorbing a certain type of specific agglutinins, have been demonstrated, but the significance of the result was disregarded because the grouping did not tally with a previous labelling, which was doubtless clinical or zoological, in the sense that the psittacosis was isolated from a parrot and the suipestifers from pigs. If the absorption test may be discarded because two strains differentiated by it cause diseases clinically resembling one another, why should one not proceed further on the same lines and refuse to pay attention to the agglutinatory and even cultural differences of organisms such as paratyphoid A and B, which resemble one another so greatly in their clinical manifestations.

In differentiating strains by means of their cultural reactions one deals with a test of a much simpler nature than that afforded by an animal body during the process of infection, and a number of characteristics have been suggested for this purpose in the case of the organisms here under consideration; for instance, the fermentation of dulcite,[3] the production of H_2S in lead acetate agar,[4] and the reduction of fuchsin in glucose serum water.[5] Whatever groups of Salmonella organisms may be mapped out by these tests the response by the ten paratyphoid B and 46 Aertrycke strains, serologically diagnosed and investigated here, was practically identical with that of the paratyphoid B group as described by Krumwiede, the only exceptions being hog cholera Arkansas (an "Aertrycke" of uncertain origin) and Kruse (an organism identifiable as belonging to the same type of "Aertrycke" as 23 other strains not giving this cultural reaction). These two organisms gave the fuchsin and lead acetate reactions, characterised by Krumwiede and his fellow workers as indicative of the suipestifer group, but on the other hand did not behave like suipestifers in dulcite peptone water; both fermented this, hog cholera Arkansas after some inducement (subculturing through dulcite) giving both acid and gas in two days, and Kruse, though it so far refuses to give any gas, having always produced acid well after one day's incubation.

These cultural reactions, therefore, do not serve to differentiate, and may even, as is recognised, cut across serological groups; the organism Kruse, for example, belongs, by virtue of its agglutinogenic and absorptive properties, to a very definite Aertrycke group, but differs from all its fellow members in not reducing fuchsin in Krumwiede's glucose serum water, not producing H_2S in lead acetate agar, and not producing gas in dulcite. Dulcite is notoriously uncertain as regards fermentation, though the only other "Aertrycke" that has so far consistently refused to do more than produce acid is one isolated in Port Said, which, in respect of all the usual carbohydrates, is a non-gas-producing variety.

Krumwiede, Kohn, and Valentine recognise a group of organisms which correspond culturally with paratyphoid B, although they fail to do so absorptively. These organisms, which he labels B. choleræ suis (intermediate types), would agree, then, in the main with the "Aertryckes" here described.

The Value of Serological Tests in Classification.

It has been seen that the type of illness associated with a particular organism does not necessarily serve to indicate how that organism should be classified, and also that it has not been possible to differentiate paratyphosus B from "Aertrycke" and the various "Aertryckes" from one another by cultural tests; what, then, are the serological differences which have served to trace out these groups?

The form in which the absorption test was carried out is as follows: ½ c.cm. of the serum to be absorbed in a 1/50 dilution (titre about 1 : 6000) is added to one agar slope of culture (25–35,000 million organisms) rubbed down into ½ c.cm. saline;

absorption for one hour and agglutination for two hours at 37° with a fresh living watery suspension of bacteria. All agglutinating sera were made by the intravenous inoculation of rabbits with heat-killed emulsions.

Owing to the complexity of the reaction and the difficulty of reading the results, the introduction of a *tertium quid* should be avoided in the absorption test. By this is meant an attempt to see if X can, for example, remove Y agglutinins from a Z serum. Only by discovering whether X can remove the specific agglutinins from Y serum can light be easily thrown on the relationship between the two organisms X and Y.

As Kruse[6] has pointed out in connexion with his work on the dysenteries, in establishing the absorptive relationship between two organisms, X and Y, it may be necessary not only to test X's power of absorbing specific Y agglutinins, but also Y's capacity for removing specific X agglutinins. This has been the writer's experience also, and may be the case for two reasons. X may agglutinate badly with Y serum, in which case it has always been found that it will absorb equally badly. For instance, the case of the organism Piper I., isolated from the urine of a paratyphoid convalescent six weeks after the onset of illness—typical para. B. was isolated from the fæces on the same day; five days later normal para. B only was recoverable from the urine. (Table I.)

TABLE I.

Paratyphoid B serum.	Agglutination against—	$\frac{1}{200}$	$\frac{1}{400}$	$\frac{1}{800}$	$\frac{1}{1600}$	$\frac{1}{3200}$	$\frac{1}{6400}$	$\frac{1}{12800}$
Unabsorbed.	Para. B Tidy.	+++	+++	+++	+++	+++	+++	+
	Piper I.	+	–	–	–	–	–	–
Absorbed with Piper I.	Para. B Tidy.	+++	+++	+++	+++	+++	+++	+++

Controls –.

While culturally Piper I. resembled para. B, agglutination and absorption with para. B serum did not further the diagnosis; it was only after preparing a Piper I. serum and carrying out an inverse or "mirror" absorption test that the fact was revealed that Piper I. was a true paratyphoid B, a typical Schottmüller removing from the Piper I. serum all its specific agglutinins. (Table II.)

TABLE II.

Piper I. serum.	Agglutination against—	$\frac{1}{200}$	$\frac{1}{400}$	$\frac{1}{800}$	$\frac{1}{1600}$	$\frac{1}{3200}$
Unabsorbed.	Piper I.	+++	+++	+++	+	–
	Para. B Tidy.	++++	+++	+++	+	–
Absorbed with Para. B Tidy.	Piper I.	–	–	–	–	–

Controls –.

On the other hand, a strain may agglutinate well with a certain serum and yet not absorb the specific agglutinins sufficiently to justify diagnosis.

T 4 F 6 is a culture isolated from the fæces of a mouse dying five days after feeding with para. B Tidy.

TABLE III.

Para. B Tidy serum.	Agglutination against—	$\frac{1}{200}$	$\frac{1}{400}$	$\frac{1}{800}$	$\frac{1}{1600}$	$\frac{1}{3200}$	$\frac{1}{6400}$	$\frac{1}{12800}$
Unabsorbed.	Para. B Tidy	++++	++++	++++	++++	+++	+++	–
	T 4 F 6.	++++	++++	++++	+++	+++	+++	+
Absorbed with T 4 F 6.	Para. B Tidy.	++	++	++	++	++	+	–

Controls –.

Whether this strain fished from the fæces plates is a selected "sub-strain" of the original Tidy, an altered Tidy, or even an alien paratyphoid B strain altogether, does not matter here; it illustrates the type of organism which while agglutinating does not absorb completely. (Table III.)

In spite of its being a good agglutinator, T 4 F 6 absorbed specific para. B agglutinins too poorly to settle its identity, but the "mirror" test was conclusive; paratyphoid B removed the specific agglutinins from a T 4 F 6 serum completely. (Table IV.)

TABLE IV.

T 4 F 6 serum.	Agglutination against—	$\frac{1}{200}$	$\frac{1}{400}$	$\frac{1}{800}$	$\frac{1}{1600}$	$\frac{1}{3200}$	$\frac{1}{6400}$
Unabsorbed ...	T 4 F 6	++++	++++	+++	+++	+++	–
	Para. B Tidy	++++	++++	+++	+++	+++	–
Absorbed with Para. B Tidy.	T 4 F 6	–	–	–	–	–	–

Controls –.

Thus it has been found that in a certain number of cases where the strain under examination is an "inagglutinable" para. B like Piper or one resembling T 4 F 6 in character, the "mirror" as well as the usual absorption test is needed to complete diagnosis, though in most cases para. B organisms of the Schottmüller type disclose their identity by at once absorbing the specific agglutinins of a para. B serum. Both forms of the test, however, are necessary in the diagnosis of an "Aertrycke"; the complete qualifying conditions being that the organism falls culturally within the bounds of the paratyphoid B group, and while either an active or a passive agglutinatory relationship to the paratyphoid B of Schottmüller is shown (i.e., either its serum agglutinates para. B, or the organism is agglutinated by para. B serum) no absorption by either organism of specific agglutinins from the other takes place.

Differentiation of B. Paratyphosus B *into Various Types.*

The serological relationship between "Aertrycke" and paratyphosus B having been so far established, it remained to be seen how the various "Aertrycke" strains stood towards one another, and the absorption test at once demonstrated the fact that there was a variety of "Aertrycke" types, differing from one another in exactly the same way as "Aertrycke" strains in general differ from paratyphoid B—i.e., the specific agglutinins of one "Aertrycke" type are not absorbable by an "Aertrycke" of another type. It is, of course, again necessary to carry out both forms of the test (to absorb X with Y as well as Y with X) before two organisms can be definitely declared of different types.

Working on these lines, the writer has been able to relegate the 46 "Aertrycke" strains into a number of types (the differentiation of the "Mutton" and "Newport" types has already been published by Captains H. Marrian Perry and H. L. Tidy, R.A.M.C.[7]), as tabulated below.

"Aertrycke" Strains.

1. *Mutton Type.*
    - Mutton. (Food-poisoning outbreak, Newcastle, 1911.)
    - H. (Food-poisoning case, Dublin, 1915.)
    - Hearfield. (Isolated by Captain Fletcher, R.A.M.C., from fæces and urine of dysentery carrier, Southampton, 1917.)
    - Wells. (Isolated from food-poisoning case by Captain Fletcher, R.A.M.C., Southampton, 1917.)
    - Port Said. (Isolated by Captain A. H. Priestley, R.A.M.C., from case during food-poisoning epidemic, Port Said, 1917.)

Allen, Blackwell, Dodds, Strong, Woodhead. (Isolated by Lieutenant-Colonel Martin, A.A.M.C., from cases in food-poisoning epidemic, France, 1918.)
A, B. (Received from Captain Perry, R.A.M.C., sporadic cases of gastro-enteritis, France, 1918.)
Brooks. (Isolated by Captain Fletcher, R.A.M.C., from fæces of Shiga carrier, Southampton, 1918.)
Amara. (Isolated from epidemic in guinea-pigs, by Major Gloster, I.M.S., Mesopotamia, 1918.)
Calf 6. (Isolated from epidemic in calves, by Captain Lawrence, R.A.V.C., Mesopotamia, 1918.)
Barnes, Hawker, Phillips, Stock. (Isolated by Surgeon-Captain Bassett-Smith from food-poisoning cases, Greenwich, 1919.)
Fulham Child. (Fatal food-poisoning case, London, 1902.)
Psittacosis. (Laboratory strain. Presumably of avian origin.)
G. Lab. (Laboratory strain. Of unknown origin.)
Kruse. (Laboratory strain. Of unknown origin).
Wassermann. (Laboratory strain. Of unknown origin.)

2. *Hirschfeld Type.*
   Priddis. (Isolated from case diagnosed as P.T.A. Peshawar, 1914 or earlier.)
   Hirschfeld's "Para. C"[10] (From case of enteric nature, Salonika, 1916.)
   Baghdad strains (9). (Isolated by Macadam,[11] Mackie and Bowen[12] from cases of enteric nature, Baghdad, 1918.)
   Witts. (Obtained from Professor Andrewes. Isolated from case at St. Bartholomew's Hospital, 1919.)
3. *Newport Type.*
   Newport. (From food-poisoning case, Newport, 1915.)
   Fentry, Hough. (Isolated by Captain Perry, R.A.M.C., from food-poisoning cases, France, 1918.)
4. *Stanley Type.*
   Stanley. (Isolated by Professor Hutchens from case of food poisoning, Stanley, 1917.)
   Britton. (Isolated by Captain Fletcher, R.A.M.C., from fæces, urine, and blood of case of enteric nature, Southampton, 1917.)
5. *Binns Type.*
   Binns, Timson. (From food-poisoning cases, France, 1917.)
6. *Arkansas Type.*
   Hog Cholera Arkansas. (Laboratory strain. Of unknown origin.)
7. *G. Type.*
   G. (From mesenteric gland of monkey dying during experiment on dietetics. London, 1917.)
8. *Reading Type.*
   Reading. (From water-supply. Reading, 1916.)

Five of the types will be seen to be definitely associated with disease in man, being represented by 24, 12, 3, 2, and 2 strains respectively.

The *Mutton* group claims over 50 per cent. of the strains, and would appear to be the most important; it includes strains from various countries and from animal as well as human epidemics; all members, as far as is known, gave rise to acute gastro-enteritic symptoms in the human cases.

The *Hirschfeld* group is, so far, a more or less geographical as well as serological entity; all cases have occurred in the East or had close connexion with Eastern countries. The clinical symptoms have been those of enteric. Further reference to this group will be found later in the paper.

The *Stanley* group is interesting in that while one member (Stanley) came from an acute gastro-enteritis, the other (Britton) was isolated on the fourth day of illness from the fæces, urine, and blood of a case clinically resembling paratyphoid fever, and was the only organism found.

Variability of Bacteria.

It is still too soon to say how constant and dependable these types are. The whole Salmonella group is considered a particularly variable one. Baerthlein[8] claims to have produced variation in paratyphoid B towards *B. typhosus*; Sobernheim and Seligmann[9] have grown strains which they regard as intermediaries between Gärtner and paratyphoid B. The only variation, however, met with in the course of this investigation has been what appears as more in the nature of a disclosure of identity, the organism becoming more agglutinable, more responsive to serological experimentation, than in the nature of a change of character necessitating the transference of the organism from one group to another. An illustration of this is afforded by the behaviour of the "Aertrycke" culture, Hearfield, which agglutinated badly with Mutton serum soon after isolation in 1917, and consequently did not absorb specific Mutton agglutinins; it was regarded as not being of the Mutton type. The making of a Hearfield agglutinating serum was frustrated on more than one occasion by the unexpected toxicity of this strain, otherwise the relationship to "Aertrycke" Mutton might have been established at once; it was only when the organism was re-tested in 1919 (with the same Mutton serum) that it could be grouped without the help of homologous serum. Hearfield had now lost its primary inagglutinability and came down to titre limit, and removed the specific Mutton agglutinins completely.

While, in the light of work done on the variability of bacteria, the possibility of impermanence in the membership of the groups here described cannot be denied, it would seem as if a sufficient degree of stability has been demonstrated to warrant attention being drawn to their existence. The acid agglutination test of Michaelis was not found useful in classifying the strains. For, although a certain correspondence was sometimes apparent, for instance, with Michaelis's lactic acid-sodium lactate mixture, all three members of the Newport group gave two agglutination maxima, the 2nd and 5th tubes, and the maximum of both organisms of the Stanley group was in the 4th and 5th tubes, yet, for the most part, the results were sufficiently confusing to prevent any classification; the Mutton group had members with maximum agglutination in the 3rd, 4th, 5th, 6th–7th, and 3rd–9th tubes. The tube of predilection for the majority of all "Aertryckes," as of paratyphoid B strains, was the 5th.

Estimated Relationship between Different Serological Types of B. paratyphosus B.

Apart from the constancy of these serological types the extent of their independence, one from another, has to be considered. It has been already stated that the "Aertrycke" types differ from one another in the same way as they all differ from the paratyphod group, but when one applies a test which, like the absorption one, is capable of detecting the finer serological differences betwen bacteria, one may expect to bring to light intermediaries existing between what are after all very closely related groups of bacteria, and this has happened apparently in one case, that of the strain Brooks. This organism, in virtue of its power of absorbing specific agglutinins from Mutton serum, has been placed in the group of that name; but it is also capable of absorbing specific agglutinins from Binns serum and must therefore be regarded as an intermediate strain between these two groups. There is this, however, to consider: the Binns group (two strains from the same epidemic) is not as sharply circumscribed as the others; it shows marked relationship to the Mutton group, as the following absorption tables (V. and VI.) illustrate. The same result is obtained with the other strain, Timson.

TABLE V.

Special mention must also be made of the Hirschfeld group, members of which have been labelled by some workers,[10] [11] [12] paratyphoid C. That this is not an historically correct classification is probable. Paratyphoid C, as described by Uhlenhuth[13] in 1908 and by Heimann[14] and Sobernheim[15] in 1912, is a Salmonella with no agglutinogenic relationship, either active or passive, to paratyphoid B. And while a number of strains in the Hirschfeld group remain unagglutinated by paratyphoid B serum, others do respond to a greater or less extent, and all give sera which agglutinate paratyphoid B strains to a considerable degree.

The following table (VII.) illustrates the varying extent of agglutinatory relationship existing between paratyphoid B and the Hirschfeld group; some badly agglutinating paratyphoid B and "Aertrycke" strains (not of the Hirschfeld group) are included for the sake of comparison.

TABLE VII.

Schottmüller's Para. B.	Para. B Tidy.	+++	+++	+++	++	++	–	–	–

Controls –.

The agglutinatory relationship, both active and passive, of paratyphoid B to the Hirschfeld type of organism may not be as well marked as it is to most "Aertrycke" types, but, as is seen in the above table, it frequently equals, or even exceeds, its relationship to certain organisms undoubtedly "Aertryckes," and, indeed, to some paratyphoid B strains themselves.

The only fundamental distinction between the Hirschfeld group and paratyphoid B is that afforded by the absorption test; it has therefore been considered to show sufficient serological relationship to paratyphoid B to be placed alongside it and the other "Aertrycke" types, rather than be accorded a position as far removed as that of *B. enteritidis Gaertner* and *B. paratyphosus C* (of Uhlenhuth). Unlike those of the Hirschfeld type, these latter organisms have no agglutinins in common with paratyphoid B and the "Aertryckes."

Nomenclature.

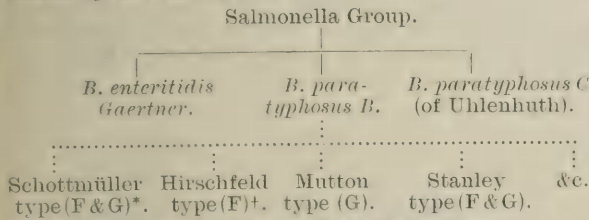
Apart from the question of relationship lies the question of nomenclature. In this paper the Hirschfeld type of organism has been regarded as an "Aertrycke." Hirschfeld labelled his strain paratyphoid C. Historically, the name paratyphosus C belongs to the organism which was described by Uhlenhuth as long ago as 1908 and by others since, and which, according to published accounts (a culture of this bacillus has not so far been obtainable), does not resemble serologically the Hirschfeld type. In view, however, of the so far constant association of illness of an enteric nature with the Hirschfeld type of bacillus, it may eventually be decided that the term paratyphosus C is more reasonably applicable to it than to Uhlenhuth's organism, which, apparently, has been isolated from human beings only in cases of acute gastro-enteritis. On the other hand, as it does not appear possible to limit consistently the term paratyphoid to organisms manifesting themselves clinically by disease of an enteric nature (Cf. Bainbridge and Dudfield's organism), there may be less reason for transferring the term paratyphosus C from one organism, to which it has been already applied, to members of the Hirschfeld type.

We have here, then, a series of organisms which includes Schottmüller's para. B, Hirschfeld's para. C, and the various types of what have been called "Aertrycke" organisms, all identical culturally, all resembling one another agglutenogenically to greater or less extent, but each type differing from the others in not being able to absorb their specific agglutinins. So long as there appeared to be but two types in this group of the Salmonellas, one represented by Schottmüller's organism and the other by De Nobele's Aertrycke bacillus, there was little need to find a name in common for them, but, with the recognition of an increase in the number of types, it has been considered justifiable and advantageous to classify them under one heading, and simplest to give this group the name of paratyphoid B. The alternative of naming the group after Durham or De Nobele, who first marked it off by the agglutination test, would still have left one with the task of inventing a whole series of new "species" names for the various types now found to exist alongside of para. B and *B. enteritidis Aertrycke*.

It is suggested, therefore, that the group be called paratyphoid B and the various subgroups regarded as so many different types of paratyphosus B—e.g., the Schottmüller type, the Hirschfeld type, and so on. The term "Aertrycke" has been omitted, as it is not yet known to which type De Nobele's strain belongs. Should, however, the Aertrycke bacillus, as is quite likely, be found to correspond with the Mutton strain it would, of course, serve as the prototype, and give its name to the group at present labelled Mutton. This amalgamated paratyphoid B group will almost certainly be found to be a very widespread and extensive one, comprising many "types" and including many of the strains obtained from diseased and healthy pigs which have been labelled *B. suipestifer*.

The Salmonella group would thus fall into two divisions (or three if paratyphosus C of Uhlenhuth is established as a separate entity), which are distinguishable one from another by the agglutination reaction, active and passive. The paratyphoid B group, with which the writer has been concerned, is further divided into types by the application of the absorption test.

Diagrammatically, the relationship of the various groups may be expressed as below. (The continued lines lead to groups differentiated by the agglutination test; the dotted lines lead to groups differentiated by the absorption test.)



* Prototype: *B. paratyphosus B* of Schottmüller.
† Prototype: *B. paratyphosus C* of Hirschfeld, MacAdam, Mackie, and Bowen.
F = Known to occasion continued fever in man.
G = Known to occasion acute gastro-enteritis.

Conclusions.

1. By means of Castellani's absorption test it has been possible to divide the "Aertrycke" group of organisms into a number of types, of which one (Mutton type) is by far the most largely represented, 24 organisms from 16 foci belonging to this type out of 46 strains from 28 foci.

2. As the various "Aertrycke" types serologically agree with, and differ from, one another in the same way as each agrees with, and differs from, paratyphosus B, the "Aertryckes" and paratyphoid B have been placed together in one group, of which they thus represent a series of types. There is some evidence for concluding that just as paratyphosus B may occasionally produce acute gastro-enteritis in man, so may a typically Aertrycke-like bacillus occasion continued fever resembling enteric. Thus there seems no good reason for separating one para. B type off from a series of Aertrycke or otherwise named types, and it is suggested as simple and justifiable that paratyphosus B be used as species-name for the whole group, the particular variety being indicated by the addition of a type-name, such as Schottmüller, Mutton, Hirschfeld, and so on.

3. Reasons for regarding as a member of the paratyphosus B group that organism which in the East is apparently of particular importance, and has been called by some workers paratyphosus C,[10 11 12] are here set forth, and the question of nomenclature is considered.

I wish to express my obligation to Professor F. W. Andrewes, Surgeon-Captain P. W. Bassett-Smith, Captain W. Fletcher, Professor H. J. Hutchens, Lieutenant-Colonel J. C. G. Ledingham, Lieutenant-Colonel C. J. Martin, Captain H. Marrian Perry, and Captain A. H. Priestley, and my gratitude for their kindness in supplying me with cultures and details of the cases in their charge.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

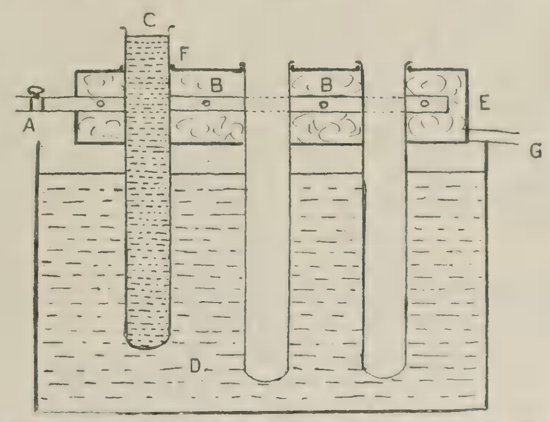
DETECTION OF ALBUMIN IN URINE:

A WHOLESALE METHOD OF HEATING TEST-TUBES.

BY GUY BOUSFIELD, M.B., B.S. LOND.,
FLIGHT-LIEUTENANT, R.A.F.M.S.

IN hospital practice the testing of a large number of urines for the presence of albumin is a matter of daily routine, and involves considerable waste of time in heating individual test-tubes over the flame. The method described below was devised with a view to time-economy, but was found afterwards to give very sharply defined results.

The apparatus consists of a flat copper steam bath, 1¼ in. deep, which is made in sections that do not communicate with each other. The upper and lower surfaces of the bath are perforated with holes, to allow of the insertion of well-fitting glass test-tubes (see figure).



A, Steam-supply pipe and cock. B, Perforated metal pipe, for steam-supply within bath. C, Test-tube, slightly raised, containing urine. D Cold-water bath. E, Steam bath. F, Raised rim to facilitate tube removal. G, Outlet pipe for condensation water.

The edges of the upper set of holes are slightly raised in order to facilitate the removal of the tubes. By this arrangement it will be seen that the heating element encompasses the upper inch or so of the test-tubes, and that owing to the division of the interior of the bath, any number of sets of tubes from, say, 5 to 40, may be subjected to the steam, allowing the apparatus to be adjusted to the number of urines to be treated, by the turning on or off of the cocks which are provided for each section of the bath. The actual distribution of steam within the bath is effected by means of perforated metal pipes which pass along the interior of each section. The perforations are so arranged that the jets of steam play between the tubes and not on to them. Reference to the figure shows that about four-fifths of the length of the test-tubes projects from below the heating element, and a cold water bath is provided to surround the greater part of this lower portion of the tubes.

Consideration of the effect of the various arrangements described above shows that (*a*) the top inch or so of the contents of a tube is heated to 100° C.; (*b*) the middle portion is brought to a moderate heat; (*c*) the lowest portion remains quite cold. The advantage of these conditions is demonstrated in the case of a highly phosphatic urine, which should be treated as follows:—

A test-tube is taken from the apparatus, filled with the urine, acidified with dilute acetic acid, and replaced in the bath. Steam is now turned on for five minutes, and on removing the tube a beautifully clear and sharply defined result is obtained. The albumin, if present, is visible in the strongly heated layer of urine, even in the merest traces. The contents of the middle portion of the tube are quite clear, owing to the fact that the heating has been sufficient to clear the phosphates in acid urine, without being strong enough to bring down the albumin. The lowest portion of contents is cold and in its original condition, and serves to contrast with the heated layers.

When dealing with a large number of urines much saving of time is effected, as 40, or even many more samples can be heated in five minutes, according to the size of the apparatus. Most hospitals have a steam-supply laid on, but failing this advantage a very small boiler on a gas-ring has been found to produce all the steam required for a 40-tube apparatus. The boiler may be started in the morning by the nurse, so that when the physician arrives the apparatus is ready for use.

The method was used by me for several months in a London fever hospital, where the number of urines tested daily was large, and I believe the original experimental apparatus is still in use there.

TWO CASES OF

TRAUMATIC RUPTURE OF INTESTINES WITHOUT EXTERNAL INJURY.

By G. E. PEPPER, L. & L.M., R.C.P. & S. IREL.

THE interesting cases reported by Mr. E. Gerald Stanley in THE LANCET of Oct. 25th lead me to record two further cases of the above injury treated by me during the war.

CASE 1.—A private in the R.A.V.C. was thrown by a restive horse, the animal falling on top of him. On admission to hospital half an hour later I found him very collapsed and complaining of great hypogastric pain. T. 96·8°F., P. 100. No dullness of abdomen on percussion, but marked rigidity. He had a hard irreducible hernia the size of a hen's egg in the left inguinal canal, but stated that it had existed for years. Catheter specimen of urine normal. One hour later he appeared worse (pulse 120), and I opened his abdomen in the middle line below the umbilicus. There was no free fluid or blood in the abdominal cavity. The hernia proved to consist of the entire great omentum, which had dragged the transverse colon down to the lower part of the abdomen, remaining attached to it by a pedicle 2 in. long. As this pedicle was severely lacerated I ligatured it and removed the mass of omentum. Four inches distal to the base of the pedicle there was a rupture of the transverse colon 1½ in. long, and this I closed with Lembert sutures. At this point of the operation the patient collapsed, and it was necessary to close the abdomen hurriedly by through-and-through sutures, one pint of normal saline, T. 100°, being poured into the abdomen. Patient rallied after the operation, but died 18 hours later. Post-mortem examination revealed a second rupture situated in the jejunum 6 in. below the duodeno-jejunal flexure.

CASE 2.—A private in the R.A.S.C., whilst exercising a restive horse, was thrown on to the pommel of his saddle, and from there fell to the ground. I saw him two hours later, and found him suffering from severe hypogastric pain, with an intense desire to micturate. There was marked dullness on percussion over the lower abdomen, and blood was obtained on passing a catheter. T. 97°, P. 100. I diagnosed intraperitoneal rupture of the bladder, and opened abdomen in middle line above the symphysis. A large quantity of blood and urine poured out, and an extensive rupture of the bladder presented; after sponging the cavity dry I closed it by two layers of catgut sutures. On examining the intestines I found two small ruptures of the ileum close to the ileocæcal valve, and closed them by purse-string sutures. The abdominal cavity was sponged dry, a large drainage-tube passed to the bottom of the pelvis, and the wound closed by layers. A catheter was tied into the urethra and was removed on the third day, the patient passing urine normally. The abdominal tube was removed on the fifth day, and the patient made an uninterrupted recovery.

These cases emphasise two points of great importance—the urgent need for early operation, and the necessity of examining the whole length of the intestines at the time of operation.

Dublin.

CASE OF

LABOUR OBSTRUCTED BY A TUMOUR.

By THOMAS H. MORSE, F.R.C.S. ENG.

SOME years ago I published a paper[1] on the Treatment of Obstructed Labour when Caused by the Impaction of a Tumour in the Pelvis, illustrated by four cases. Since then another similar case has occurred as follows:—

CASE 5.—I was asked to see Mrs. D., who had then been in labour 48 hours, and was becoming exhausted. Pulse was 120, and pains were recurring about every three minutes. On examination per vaginam a semi-solid tumour occupied the pelvis, and with difficulty the finger could reach the presenting head, which had not yet engaged in the pelvis, but remained above the brim; the os uteri was fully dilated. The pelvis was so blocked that forceps and other instruments could not be passed into the uterus.

I decided to open the abdomen. She was at once removed in a cab to a surgical home. An incision about 11 in. long was made in the middle line of the abdomen as rapidly as possible, and the whole fundus of the uterus turned out. Mr. A. Ross, who assisted at the operation, very carefully kept it covered with hot sponge cloths. The right Fallopian tube and round ligament formed a tight cord passing behind the fundus down into the pelvis. On tracing this I found it attached to a tumour filling the hollow of the sacrum; this was about the size of a cocoanut, it was not adherent, and was easily drawn upwards and out of the wound; its pedicle was long and twisted upon itself. Having ligatured it with silk, the tumour was cut away; on examination it proved to be a dermoid ovarian cyst. The uterus was now with some difficulty replaced, as the parietes seemed insufficient to cover it; however, this was finally accomplished. The whole operation had to be rapidly performed, the pulse having reached 130 per minute before beginning. Brandy enemata were given and strychnine hypodermically, and the patient rallied quickly. The wound was dressed temporarily, and then Mr. Ross applied forceps and delivered the child, which, although well developed, was dead, the result, no doubt, of the prolonged labour. The after-treatment was quite satisfactory, and the patient was quite well in a week.

As cases of this kind will recur it will be a gratification to me to find that the method described above has become the recognised form of treatment, and that it can be easily carried out by the surgeon of the present day.

Deal.

Reviews and Notices of Books.

THE GREAT WAR AND THE R.A.M.C.

By Lieutenant-Colonel F. S. BRERETON, R.A.M.C. London: Constable and Co., Ltd. 1919. Pp. 300. 12*s.* 6*d.*

IT is a truism that, for the combatant and non-combatant sections of an army, war and battle wear different aspects. The combatants face death, nerve-racking situations, hunger, weariness, and, sometimes worse than all, retreat. But against all these they have one great item on the credit side—namely, that sensation which is referred to again and again in the finest and oldest battle story in the world, the Iliad, as χάρμη, "the joy of man-ennobling battle," to quote Homer's phrase. For the non-combatants all the ills are present without this redeeming feature. Transport, ammunition columns, despatch riders, and, above all, the R.A.M.C., face every conceivable hardship and risk, while this "battle joy," when theirs, is theirs in other circumstances. It is one thing to fight when it is a question of kill or be killed, but far other to do duty with the chance of being killed, knowing that reprisal is not in the official programme. The R.A.M.C. above all others glean the sad aftermath of the harvest of war. To use homely language, they have to clean up the mess, and in the volume before us, which is the first of a series dealing with the medical work of the war, we have the record of the R.A.M.C. during the first two months of the conflict, comprising the operations around, and during the retreat from Mons, and the events of the battles of the Marne and the Aisne. The medical service was sufficient in size and equipment for the comparatively tiny army which was our first contribution to the war, except in the matter of transport; but as the army grew, an almost new medical service had to be improvised. After the first two months the auxiliary aid of the Red Cross Association and the St. John Ambulance Association had to be called in, to say nothing of the thousands of civil hospitals that were founded in private houses and municipal buildings for the care of the ever-increasing number of wounded. These matters, however, are outside the scope of the volume before us.

We have said that the medical service was deficient in transport, but Colonel Brereton is careful to point out that this was not the fault of the medical authorities. Horse transport there was in plenty, but the Director-General even before the war had foreseen the necessity for the increased mobility afforded by motor ambulances, had asked for them, and had been refused. The result of this unhappy decision became only too evident in the first hours of the war. "Seek the evidence of wounded officers and men who passed through purgatory on horsed ambulances and motor lorries. Question those unfortunate men of Mons, prisoners since 1914, wounded in the first hours of the war—abandoned for lack of transport. The dead yield no word of these doings. Yet men died for this self-same reason." Not until the operations on the Aisne were the motor-ambulances, so urgently asked for by the Director-General, supplied, and the lack of transport and its results during the great retreat from Mons are vividly described by Colonel Brereton—a retreat marked by misery and heroism only comparable to those historic retreats of the Athenians from Syracuse and the British from Astorga to Corunna, which live for ever in the narratives of Thucydides and Napier. Again and again we read of field ambulances breaking down, of wounded having to be abandoned, of ambulance horses being utterly worn out, and of the wounded having to be carried on artillery wagons and impressed civilian carts, with the result that the artillery horses also broke down, so that the guns were held up. There is more than mere sentiment in the beautiful prayer of the Russian Church in time of war: "And then for those, the humble beasts which with us bear the burden and heat of the day, we pray Thy pity, Master and Lord," for the avoidable sufferings of animals react with untold evil upon men.

Colonel Brereton's account of the heroism of all units of the R.A.M.C. is a moving tale, told with all due reserve; he mentions many names, but every man, from officer to stretcher-bearer, did his duty, and that under circumstances of inconceivable hardship, and many a one laid down his life. Nor must we omit to remember those whose deeds are enshrined in the report of the committee which investigated the typhus outbreak in the camp at Wittenberg. It will be within the recollection of all that the German Medical Staff abandoned its duties when typhus broke out, but the German Government sent six British medical officer prisoners—Major Fry, Major Priestley, Captain Sutcliffe, Captain Field, Captain Vidal, and Lieutenant (afterwards Captain) Lauder. Of these six Major Fry and Captains Sutcliffe and Field were attacked by typhus soon after their arrival and died. The other three lived to return. What they did may be read in Appendix II. of Colonel Brereton's book. As to the medical orderlies, "They, all of them, with full understanding, for they were all warned, risked their lives without a thought, and many of them died at their posts." We congratulate Colonel Brereton upon this, the first instalment of his book, which should stimulate readers to expect with eagerness the sequel.

ANESTHÉSIE À LA STOVAÏNE.

En Chirurgie et en Médecine Vétérinaires. By GUSTAVE PÉROL. Paris: Masson et Cie. 1919. Pp. 32 and plates. 3 francs.

GENERAL anæsthesia is ill-adapted to the larger animals, and M. Pérol in this little treatise shows good reason why local and regional analgesia deserve much wider recognition than they have yet received from veterinary surgeons. The risk and inconveniences inseparable from the felling of animals, necessary when no anæsthetic is employed, are all avoided, and the beast, moreover, experiencing no pain, is amenable when it comes again under treatment. A solution of 2 per cent. stovaine is recommended, and as much as 100 c.cm. may be injected into a horse without producing any general reaction. Cocaine, on the other hand, gave rise to trembling and profuse sweats. Adrenalin (1 in 1000) is used with the stovaine. Details of various common operations are printed, and a few excellent photographs of the method at work.

LE MYTHE DES SYMBIOTES.

By A. LUMIÈRE. With 47 illustrations. Paris: Masson et Cie. 1919. Pp. 209. 6 francs.

IN "Les Symbiotes" Portier proposes that all animals and plants are double symbiotic organisms, and that each of their cells contains a special microbe which plays an indispensable part in their life and metabolism. He was able to cultivate this remarkable organism from the tissues of healthy animals, and finds that it is identical with the mitochondria of cytologists and the vitamines of the bio-chemist. In the present volume, well printed and illustrated and cheap, Lumière points out, firmly and quite gently, that the available facts do not altogether support the hypothesis. It is well known that bacteria of one sort and another occasionally gain entrance to, and may be cultivated from, healthy tissues, and in an interesting review of symbiosis, cell inclusions, and vitamines, he traverses various biological problems in a readable fashion. The book closes with a graceful word of thanks to Portier for starting such an entertaining and profitable hare—thanks in which we may all join. For it is certainly proper to consider and reflect on the relations which have been established between moulds and the growth and germination of orchids and heaths, on the nature and meaning of the intracellular bacillary bodies in Blatta and Cyclostoma, on the real possibilities of a healthy aseptic existence, on the connexion between vitamines and the synthetic activities of intestinal bacteria, and generally on the due limitation of the imagination. There is a useful bibliography of 49 pages.

CHILD WELFARE.

The Teachings of Certain Dentists. School Medical Officers. Medical Officers of Health, and other Medical Men. By J. SIM WALLACE. London: Baillière, Tindall, and Cox. 1919. Pp. 102. 5*s*.

THE works of Dr. Sim Wallace are always interesting. His latest book is really a reprint of papers contributed to various societies and journals since 1914. In company with a few leaders of dental thought in this country, he realises that the pathology and ætiology of caries are sufficiently well known to support effective measures for the prevention of this disease, which is probably more easy to prevent than any other. And although the methods of prevention have been taught for at least the last 15 years, dental caries is still rampant in our midst. Dr. Sim Wallace believes that the onus of spreading the knowledge of how to prevent dental disease is upon all those who come into intimate relation with parents and children—i.e., medical practitioners, school medical officers, nurses, and school teachers. He has some hard words to say about those responsible for educating the medical man, and lays particular blame on the physiologists for their lack of knowledge of the elements of oral hygiene, feeling that, until these laws are understood by those responsible for the welfare of the child, progress will be slow in preventing dental disease.

The amount of dental disease amongst the individuals forming the nation lowers the health of the nation as a whole, and depreciates the economic value of the worker. There are signs that an attempt is to be made to deal with this problem by the creation of a public dental service. We draw the attention of those responsible for the creation of any service to this little book, for it will help them to recognise that the right way lies not in starting curative centres, but in the broadcast dissemination of the means of prevention. Thousands of pounds of public money may be saved in this way, and dental disease effectively combated.

AN ATLAS OF DENTAL EXTRACTIONS.

With Notes on the Causes and Relief of Dental Pain. By C. EDWARD WALLIS. Second edition, with 11 plates. London: J. and A. Churchill. 1919. Pp. 23. 5*s*.

THE author has designed this small work for the use of medical students and practitioners, and he has, we think, succeeded in producing a very useful book. The medical man who is called upon, in an emergency, to extract a tooth has not at hand a modern dental operating chair, and has therefore to make shift with an ordinary arm-chair. The author, having realised this, has shown how the operation of tooth extraction can be carried out in an "improvised dental chair." The technique of the methods of removing the different teeth is clearly and concisely stated, and should prove of great practical value. We think that the book will reach another edition, and we would therefore suggest to the author, when he is revising his work, to describe more fully the method of plugging sockets in cases of bleeding, and also to make quite clear that the bleeding is not always from the tooth socket, but sometimes from torn vessels in the gums. We would also point out that calcium lactate is more efficient when freshly prepared.

THE PHYSICAL CHEMISTRY OF THE PROTEINS.

By T. BRAILSFORD ROBERTSON, Ph.D., D.Sc. London: Longmans, Green, and Co. 1918. Pp. 484. 25*s*.

THE protein group has received intensive study during the last decade with results of increasing interest and importance. The situation as it stands is admirably presented in this volume and it is doubtful whether a more complete or up-to-date account exists, the author having taken extraordinary pains to exhaust past and current literature on the subject. Proof of this is seen in the references to such an important investigation as that of Van Slyke, who developed an accurate and simple method of determining free amino groups; to the work of Pauli upon the combining capacity of de-aminised proteins; to that of Schmidt and B. af. Ugglus upon compound proteins; of Procter upon the swelling of protein jellies; of Reichert and Brown upon the crystallography of hæmoglobin, and of Dabrovsky upon the molecular volumes of proteins dissolved in water and in solutions of coagulating salts. The book is a valuable and welcome contribution to the subject.

AIDS TO THE MATHEMATICS OF HYGIENE.

By R. BRUCE FERGUSON, M.A., M.D., B.C. Cantab., D.P.H. Eng. London: Baillière, Tindall, and Cox. 1919. Pp. 186. 3*s*. 6*d*.

THE fifth edition of this valuable little pocket-book is even better than the previous editions, the most notable new points being an explanation of the term millibar which is now so frequently used in barometrical records, and an important addition to the chapter on Energy, Exercise, and Diet. Questions that have been set in the various D.P.H. examinations are given on each subject; most of them have been worked out in full, and are so clearly and simply expressed that the most unmathematical reader can easily understand them. The following is one example: How much sewage would be discharged in three hours by a sewer, circular in shape, with a diameter of 18 in. and a fall of 1 in 180, running half-full? The amount is shown to be 2,565,427 gallons. The chapters on the construction of a hospital ward and on vital statistics are especially noteworthy. It is not merely a book for students, but is a reliable book of reference that might well be on the table of every public officer of health.

OPERATIONS ON HUMAN CORPSE AND LIVING DOG.

Operationsübungen an der menschlichen Leiche und am Hund. Von Professor Dr. G. AXHAUSEN. With 132 plates. München: J. F. Lehmann. 1919. Pp. xii + 308. 50 marks.

THIS work is not a text-book in the ordinary sense, but is rather a series of "exercises" in academic operative surgery, and it gives us throughout an impression of being divorced from reality. It contains descriptions of a series of operations on the dead human body and on the living dog, and an industrious German student, having worked conscientiously through it, would no doubt imagine that he was well equipped to face the exacting demands of the operating theatre. But he would be mistaken. It is a book with large pretensions; the descriptions of operations are clear; but the author's omissions are, to an English reader, remarkable and some of the methods described still more so. Certain examples may be given. In the section on amputations we have very full descriptions of the operation of amputation of the foot according to Chopart and Lisfranc, but Syme's operation, which, by English surgeons at any rate, is preferred to any other, is not even mentioned. It is difficult to believe that the author's choice really represents the result of German experience. In the section on cranial surgery the ordinary operation of trephining is not described; the author concentrates on the fashioning of an osteoplastic flap, but gives the impression that the only method of opening the skull which is known to him is effected by means of the chisel and mallet, the more refined methods of modern surgery not being mentioned. In describing the operation of appendicectomy the author refers to the pararectal incision, but dismisses it as inferior to the "outer incision." He then describes this very fully, and remarks that the muscles may be divided in the line of their fibres, but he evidently regards this as an unnecessary precaution, for all his very careful drawings of the stages of the operation show the muscles ruthlessly divided in the line of the skin incision.

That part of the book which is devoted to operations on the dog points to a difference in national systems of education. The German student is able to familiarise himself with the technique of abdominal surgery by practising on the dog; in this country such work is only done by experts and for cause shown.

An immense amount of trouble and expense has been devoted by the author and the publishers to the illustrations, which are extremely good. The numerous coloured plates are masterpieces of colour printing, a process in which Germany has long excelled.

THE LANCET.

LONDON: SATURDAY, JANUARY 10, 1920.

Rewards for Medical Discovery.

WE publish in another column a report which is to be presented to Government at an early date by a Joint Committee of the British Medical Association and the British Science Guild, the object being to ensure that medical discovery shall be more adequately rewarded by the State than it is at present. The Joint Committee, it will be seen, has a strong personnel, and the document sets out their considered point of view in clear terms. Medical discovery is defined, under two heads, as being (1) the ascertaining of new facts or theorems bearing on the human body in health, and the nature, prevention, cure, or mitigation of injuries and diseases of human beings; and (2) the invention of new methods or instruments for the improvement of sanitary, medical, and surgical practice, or of scientific and pathological work. With these definitions no one can quarrel, but it will occur immediately to all minds that considerable discussion may arise over the word "new." Medical science is essentially evolutionary, the departures of the present being alike founded on the knowledge of the past and directed towards the developments of the future. At almost every point in the history of a medical discovery part of the work is old while part of it is new. A great proportion of medical investigation is necessarily engaged at first on the testing and perfecting of the old: at what point does the work become "new," and therefore eligible for an award under the definitions of the Joint Committee?

The reasons for rewarding medical discovery are set out as twofold—to encourage medical investigation, and to discharge a moral obligation incurred by the public for its use of private effort. In the first of these reasons we find some answer to the difficulty we have set up. It is to encourage medical investigation that money is required, so that rewards for the results of discovery may, partly at least, be received while the inventor is engaged at his work. The more this situation is encouraged, the further into the background recedes the need for pensions. Undoubtedly at the present moment the scientific investigator, as far as the profession of medicine is concerned, is quite unfairly rewarded. Apart from titular honours and dignities, he can have little to look for except small professorial or tutorial fees, or some inadequate return for his educational work; while alike as professor, demonstrator, or lecturer he spends a large part of his time aloof from any commercial contact with the public. Most of our educational leaders have been persistently underpaid for that part of their work; now that we all see in properly directed research the great future of medicine, it follows that those who direct should be properly remunerated. From their work will come the discoveries that mean immeasurable benefit to the State.

The Report divides medical discoveries into those which have cost the investigator direct or indirect monetary sacrifice, those which have brought return to him by an increase of professional emolument, and those which involve neither gain nor loss to him, the last class being the largest. It is clearly unjust that medical discovery which may be of extreme value to the public should entail financial loss upon him who has made it, and where this is the case compensation should be forthcoming, though the determination of the actual figure will often be a delicate task. The Report suggests that the following four things should be taken into account: Width of application, difficulty of work done, immediate practical utility, and scientific importance; and under the last three of these four headings a properly selected body of almoners should have no difficulty into coming to just decisions. But when such a body of almoners come to consider width of application of a medical discovery they will at once be faced with the difficulty which we have foreshadowed above, and the Report reveals this, although not in so many words, when it says that the work of many of the older anatomists, physiologists, and parasitologists, of PASTEUR, and of investigators of immunity, has affected most recent discovery. The wider the good effected by the departure the more difficult will it be to decide if it is "new." We have purposely set out some of the difficulties before the Joint Committee in making out the case; it only remains to say that we are wholly with the spirit and objects of the representation.

◆

The Outlook in Psychotherapy.

"IN the world there is nothing great but Man; in Man there is nothing great but Mind"—the words of Sir WILLIAM HAMILTON are engraved in letters of gold on the walls of his old classroom in the old University of Edinburgh. Is the day at length dawning that is to see full recognition of their truth, and is the medical profession to play a leading part when Mind comes to claim its kingdom, or shall it be content to follow where others lead? He who reads the signs of the times is aware of a surging movement towards the doors beyond which opens the world of the psyche, an insistent stretching out for the key to unlock its mysteries. No material explanation of the simplest phenomenon satisfies the man for whom modern journalism caters: CARPENTIER prevails, because of the glamour of hypnotism; untutored ladies know not what they paint, but lo, on reversing the picture, it is seen to have become, through "spirit guidance" and by "psychic power," a head of the CHRIST. What though the smile of superior knowledge curl on the lips of the sceptic?

What though the persons concerned can ridicule the pretensions to mysterious influence with which they have been credited? Has not the average man heard on every side of communication with those who are gone, of visions on the eve of battle, of the angels of Mons and the Poltergeists of Sir Arthur Conan Doyle?

Let those of us, however, who are indifferent to such examples of the will to believe, bethink themselves how closely they are concerned in the equally insistent trend towards mental healing. No consultant but learns how patients drift off to some irregular practitioner with electricity in his finger-tips, no sufferer but has heard of the cures, invariably marvellous, effected by some who are outside the pale, and of whom it is alleged we are jealous. Yet why should we be? The proper and rational application of psychotherapy in suitable cases is being successfully conducted by scores, nay hundreds, among us, who have their grateful patients just as much as any Eddyite, faith-healer, or "new-thought" expert. If we ask why it is that such self-constituted therapists flourish in our midst, the answer is obvious. In the first place, a proportion of the medical profession still looks askance at anything savouring to them of the mysterious or the unknown; for them hypnotism suggests mesmerism and disgusting public performances of other days, not free of a considerable admixture of the fraudulent; Freudian psycho-analysis means a nasty mind, wallowing in sexual garbage to the detriment of practitioner and patient alike; suggestion implies the merest trifling with a symptom, to the exclusion of any genuine effort to find a cause. The prejudices of these our confrères, be it said plainly, are based on simple ignorance of the facts. And this leads to the second point, which is that no schools of rational psychotherapy have ever been established for the instruction of the student of medicine, undergraduate or post-graduate; as he is laboriously taught how to stain a section of a fatty liver but not how to prevent the liver from becoming fatty, so the complete paranoiac is paraded before him in the institution, but no systematic initiation into the prevention, recognition, and cure of the earliest stages of the mind diseased is ever attempted. When have we had in this country a school of psychotherapy with the reputation of the schools of Nancy and the Salpêtrière, faded though it now may be? Why are the great names in psychotherapy monotonously foreign? The student picks up a few crumbs in a haphazard fashion, but how many of us, by the day we received our diplomas and were licensed to practise medicine, had actually seen cases of functional nervous or mental disease treated and cured by an expert in the subject? It is little wonder, then, that a valuable paper such as that published by Dr. W. A. Potts, on Psychotherapy in Ordinary Practice, in a recent number of The Lancet,[1] should seem to not a few a departure, opening a new field of the existence of which they have been in regrettable ignorance. It is no answer that treatment by psychotherapy is as old as the hills, and the ancient platitude that physicians employ suggestion habitually, if perhaps unintentionally and unconsciously, no longer suffices. Until the approved methods receive recognition in the medical schools, and the application of theoretical knowledge to concrete cases is there displayed, so long will dissatisfied patients flock to those who may, indeed, be unacquainted with the morbid anatomy of general paralysis, and have never heard of schizophrenia, but who can remove a psychic neuralgia or give the weary sufferer sleep. There is no reason in the world why the same proportion of our young graduates should not turn their steps in the direction of psychotherapy as at present are attracted by any of the specialties.

It has ever been the boast of the profession that they have tried to elevate mankind to their own standard of scientific knowledge, and that improvements in the mental and physical hygiene of the race have been preceded by the discoveries of medicine. We must see to it that we lag not behind in our application of psychological methods to psychological disease or to functional symptoms in organic disease. Undeterred by the indifference of some in the high places of medicine, and equally uninfluenced by the exaggerated claims of the extremists and the absurdity of their attitude, we should seek to ensure that the new generation in medicine will at least have the chance of learning its psychotherapy under happier auspices, and in a different atmosphere than in the days that are passed.

War Nephritis.

The problems of military medicine are always changing. When one disease has been apparently scotched, another raises its head. Typhoid and dysentery were reduced to comparative impotence in this war, though veritable scourges in the South African war. Malaria has proved a more serious matter, while nephritis, so rare in warfare, assumed an epidemic form—so far as we know, only for the second time. Among the Allies it appeared first in Flanders among the British in March, 1915, but did not affect the French until July of the same year. Less common among the Belgians than either the French or the British, it was infrequent in the Italian army. The Germans first recognised it in the troops on the swamps at the Eastern front. It would be of great interest to know whether it appeared there earlier than on their Western front, in view of the suggested infective origin. It might be held that it is unlikely that an epidemic would start at two widely separate points, but, remembering the free transference of troops between East and West practised by the Germans, this argument can carry little weight, especially as it was the British observations which first called attention to the existence of the disease on the Western front. It is noteworthy that on both fronts it first appeared in swampy or flooded territory. Our authorities, with the coöperation of the Medical Research Committee, lost no time in investigating the disease. Wards were set aside for its observation at St. Bartholomew's Hospital, and a preliminary report was issued in the *Journal of the Royal Army Medical Corps* for July, 1915, by Dr. LANGDON BROWN. Both in France and in this country many observations were made, and in 1917 the Committee provided the services of Dr. HUGH MACLEAN, who designed and carried out in France an investigation of a far-reaching character. Captain DE WESSELOW and Captain J. A. WILSON were associated with this work and reports appeared from time to time. A final report has now been issued by Dr. MACLEAN in a convenient form, which embodies not only his own able and laborious research, but also a generous acknowledgment of the work of others.

---

[1] The Lancet, 1919, ii., 1123.

That war nephritis could be due to military training seems, a priori, unlikely, since it has been an unusual accompaniment of wars in the past, and it occurred early in this war before the less fit population was drawn upon. But it is not sufficient to rely on a priori considerations, and it is well that Dr. MACLEAN has taken the opportunity to investigate this point fully, since it helps to throw light on the ætiology of nephritis in general. He examined 50,000 men who had practically completed their training, and found that not more than 2 per cent. gave any definite indication of kidney disease as indicated by the presence of albuminuria and a fairly large number of casts. Other definite signs of renal disease were found in about 1 per cent. The albuminuria produced by sudden severe exertion passes off on resting, and does not become any more marked with prolonged training. Nor does the incidence of albuminuria and casts tend to increase with length of service; it is, indeed, commoner in the younger soldiers from 18 to 20 or so. No relationship could be made out between albuminuria and previous occupation in civil life. The subsequent history of these 50,000 men is instructive. Only 161 were returned as possibly suffering from nephritis, and of these only 28 had shown albuminuria before going into the trenches. It is curious to note that the disease generally attacks its victims fairly quickly after their arrival in the trenches, for of these 161 49 became ill within two months, while within four months 106 cases had developed. This suggests that there may be some special liability in those affected, but the influence of training for active service can be eliminated as a factor in that liability; nor is pre-existing albuminuria responsible, since the majority of the men who contracted the disease were known to be free from albuminuria a short time before.

Reviewing the ætiology, MACLEAN agrees with LANGDON BROWN and others that exposure, water-supply, diet, alcohol, metallic poisons, and previous illnesses cannot be held responsible, and concludes that war nephritis is probably due to some special infective agent. But he shows that once the disease was established in the army there was a definite seasonal variation, the curve of incidence showing an inverse relationship to that of the temperature. But he holds that cold and exposure do not initiate the mischief, though they no doubt often aggravate it. There is evidence that slight but undoubted symptoms of nephritis, developing during the summer but not necessitating admission to hospital, may recur during the winter months in a severer form, and then for the first time figure in the statistics. That war nephritis is due to an infection cannot be regarded as definitely proved, since the various claims to have isolated the infective agent have never been confirmed. But if it were dependent on any circumstance connected with the war other than infection, it would almost certainly give a higher incidence in those with inadequate kidneys, which is not the case. It is interesting to note that a unit with a high incidence of nephritis at the front continued to show it for some time when at rest, which would indicate that when the infection is once established it persists apart from locality. Colonel A. B. SOLTAU found that when troops were stationed in certain localities which appeared to be more infected they developed a high rate of nephritis in course of time. MACLEAN adduces evidence suggesting the conveyance of the infection by means of body vermin—probably lice—and is of opinion that if this assumption is granted all the anomalies and difficulties in connexion with the ætiology of the disease disappear. That it is an epidemic infection associated with prolonged occupation of trenches is further suggested, as pointed out by LANGDON BROWN, by the conditions under which it appeared in the American Civil War, the only previous war in which nephritis occurred in an epidemic form. That the infective agent is a filter passer is probable but not proven. The very uniformity of the clinical symptoms may be taken as further suggesting a common infective origin. Later observers have added very little to the early descriptions. Dyspnœa, which is such an important symptom in war nephritis, remains its only special peculiarity, and is possibly due to the local lesions in the lung described by DUNN and MCNEE. The morbid anatomy may be summed up as an acute lesion in the form of blocking of the capillaries of the glomeruli and less marked changes in the epithelium of convoluted tubules of the kidney, accompanied by desquamation of epithelium in the bronchioles and pulmonary alveoli, with fibrinous deposits on the denuded surfaces.

It is noticeable that hydræmia was present in the majority of cases, and appeared to be closely connected with the rise of blood pressure. Cardiac enlargement chiefly occurred in those patients who had struggled on for some time before admission to a field ambulance, and was usually of a temporary character. Urea retention occurred in the earlier stages of moderately severe cases, but, as soon as the kidney lesion improved to some extent, this retained urea exerted its diuretic action with the result that marked polyuria occurred. There is a distinction between an azotæmic form showing little œdema, with the output of diastase and urea diminished, while that of the chlorides is normal, and a hydræmic form with œdema, normal output of diastase and urea, but that of chlorides much reduced. In the former type MACLEAN advises a low protein diet until nitrogenous retention disappears. In the latter he only restricts protein diet in the acute stages, but cuts off salt. He agrees with most other observers that stimulating diuretics are valueless; nor has he much to say about the benefit of any other drugs. Venesection for convulsions, hot-air baths and purgation for œdema, and gradual exercises in convalescence, all meet with his approval. The immediate mortality throughout was low—probably about 2 per cent. Dr. S. C. DYKE found complete recovery in 60 per cent., while in 40 per cent. the re-establishment of renal function was incomplete.

So far this report summarises in convenient form observations which in the main have already been published. But in addition four tests for renal efficiency are described. Three of these had been previously employed—the estimation of the urea in blood by Van Slyke's method, the estimation of urinary chlorides, and the estimation of urinary diastase introduced by WOLGEMUTH which was applied to the earlier cases in this epidemic by MACKENZIE WALLIS with marked success in determining prognosis. But the remaining one is new and simple, and may prove of value in ordinary nephritis. Fifteen grammes of urea are dissolved in 100 c.cm. of water, and the mixture flavoured with a few drops of tincture of orange. The patient empties his bladder and then drinks the solution. He empties it again one and two hours later, and the percentage of urea in these specimens is estimated by the hypobromite method. A concentration of 2 per cent. or more in the first specimen may be taken as evidence of an efficient kidney, rendering examination of the second unnecessary. A moderately efficient kidney may show a concentration of 1·5 per cent., while 1 per cent. or less means that the kidney is seriously damaged. It is claimed for this test that it has been of great value in assessing the degree of disability produced by war nephritis. The part played by Sir WALTER FLETCHER, the secretary of the Medical Research Committee, has been very valuable; his initiative and persistent interest in the subject have made this important series of observations possible.

MONYHULL COLONY FOR EPILEPTICS AND THE FEEBLE-MINDED.—Monyhull was during the war an important section of the 1st Southern General Hospital, which had taken over large buildings recently erected. These buildings will now revert to their proper use for epileptic and feeble-minded children, and form an addition to the older colony for adults. The committee have wisely expressed the view that great opportunities will be provided for investigation, and have decided to make arrangements for medical research. The colony will be the largest establishment of its kind in the country.

Annotations.

"Ne quid nimis."

SCIENCE AND INDUSTRY.

UNDER the stress of war, especially in the last two years, time-honoured prejudices yielded to a fuller and freer discussion of essential aims. As a result of this salutary process many kinds of industry came into more intimate touch with scientific research, which in its turn found new objectives of great interest. Science, in fact, began to rejoice in its heritage of vivifying and explaining the common things of life. Of the institutions in this country which contributed to this desirable result none earned a higher place than the Imperial College of Science and Technology at South Kensington. Enjoined by its Charter to train students in science, with special relation to the needs of industry, this college, on the recommendation of the Haldane Commission on University Education in London, became a constituent unit of London University in the faculty of science. In the final report of the Commission it was stated, in contrast with other foundations, that the Imperial College was so well equipped and so efficiently staffed that no further provision was held necessary in order to qualify it for inclusion as a constituent college of the University. At the same time the Royal Commission expressed a difficulty in regard to a faculty of technology. "It would be unfortunate," the report runs, "if the teaching of pure science were altogether removed from the college. It would be detrimental to the students by narrowing the range of intellectual interests represented among them, and equally detrimental to the technological teachers whose work is based upon the principles of pure science and who find in the investigations of the pure scientist the support and suggestions which lead to fresh applications of a practical kind." The hope was expressed in the report that the Committee for Technology should not organise their departments in a way detrimental to the faculty of science as a whole. The misgivings of the Commission do not seem, however, to have been realised quite in the way expected, for in a letter to the *Times* of Dec. 31st, over the signatures of 22 members of the professorial staff of the Imperial College, it is asserted that the college has, from its foundation, endeavoured to carry out the injunction to train students in science with special relation to the needs of industry, not by sacrificing the methods of science but by adapting them to specialised needs. The signatories, who number among them 13 Fellows of the Royal Society, claim that there is room both for the more academic and the more utilitarian aspects of science, and admit no fundamental deviation in principle involved in training with industrial needs in view. The brief period of association with the University of London has been felt by the college staff, not as a stimulus to scientific work, but as a drag upon the best prospects of development, and this feeling took the form of a deputation to Mr. Balfour and Mr. H. A. L. Fisher on Dec. 15th, when the case for the granting of its own degrees by the Imperial College was ably set forth by Professor W. W. Watts and others. The force and cogency of their arguments cannot be resisted, and upon them they build a plea that their specialised and independent curricula should lead to degrees granted on their own responsibility alone. The final science examinations of the University of London are different in plan and in character, with the result that second-rate students of the Imperial College may obtain first-rate degrees and vice versa. The needs of industry are so pressing, and its scientific development is changing so rapidly from year to year, and almost from month to month, that flexibility must be regarded as an essential part of any union of science and industry. Professor M. J. M. Hill, in a reply to the joint letter published in the *Times* of Jan. 3rd, states that public opinion is not yet ripe for dispensing with external examiners in science degrees, or, as another writer has put it, "branding your own herrings." Professor Hill suggests a modification of the statute allowing the examiners for the degree to consist of the student's teacher and an external examiner, plus a referee to act only in the event of a difference of opinion arising between the other two. It is doubtful whether such a liberal concession as this will now content the professorial staff of the Imperial College. They have a vision of science in relation to industry not less noble than the academic science of the last generation, and we have little doubt that they will attain their object. If they do so it may set the precedent for the disruption of the University, as Professor W. H. Bragg and Professor E. H. Starling plead for a similar release of University College and King's College from what they have in practice found to be a deterrent influence. Dr. H. E. Armstrong, in another contribution to this correspondence, would grant autonomy to each college, encouraging each to assume special features: the Imperial College as a centre for physical science and engineering, University College as a centre for biological science, King's College as a centre for arts. As this would mean that certain faculties might be unrepresented in a particular University strong resistance can be anticipated.

VACCINATION AND THE WAR.

IN the Swiss medical journal *Correspondenz-Blatt* of Dec. 4th, 1919, Professor G. Sobernheim, of Bern, contributes some observations on the behaviour of small-pox and vaccination among the Central Powers during the war, with special reference to precautions which may be requisite to keep small-pox out of Switzerland. Vaccination was again on its trial, the occasion was unique, and there was an experiment on the grandest scale. Once again the protective value of vaccination was proved beyond all shadow of doubt. It is chiefly as a source of illustrations of this thesis that Professor Sobernheim's ten pages of observations are of value. The German military machine had suffered from small-pox in 1870–71. Accordingly universal compulsory vaccination was installed in 1874 as a military measure. The testing time arrived, and the wisdom of the vaccination policy was abundantly vindicated. Dr. Sobernheim makes the interesting observation, for instance, that small-pox among the civil population in Berlin was a disease of older persons, in whom vaccination had partly worn out; in 1917 80 per cent. of the small-pox cases in Berlin were over 40 years of age. The younger people, in whom vaccination was recent, scarcely suffered at all from the disease. Another striking fact was the behaviour of small-pox among the various classes of Poles. Among many of the Jewish population hygiene was of a low standard; their houses were poor and insanitary; the inhabitants were dirty; typhoid and other infections were prevalent, with the exception of small-pox, which had a strikingly small incidence. Among other classes of Poles who were cleaner, more hygienic, and better circumstanced in sanitation generally, small-pox had a very heavy incidence. On a review of all the factors and circumstances which could bear on this remarkable difference in the incidence of small-pox, there was to be found only one explanation which could account for the phenomena—namely, the fact that the Jewish population was well vaccinated, the others were not. It was evidently a case of survival of the fittest, and the Jews, knowing how to look after themselves, survived.

As regards the incidence of infectious disease among the soldiers, the same events which occurred among British troops are related by Dr. Sobernheim to have occurred among the German troops—that is to say, it was recognised that individual hygiene was impossible; men could not possibly escape infection as they could in civil life, nor could cases of small-pox be isolated as they occurred. Therefore the only available expedient was to immunise the individual in order to make him efficient. This was done by revaccination on the soldiers joining up, and also, where necessary, in the camp and field. Vaccination of the civil population was less efficient. The result was seen in 1915, for instance. In that year small-pox attained such proportions in Austria that the deaths from it were 23,500 (giving a case-incidence of at least 100,000). But the disease did not spread in Germany. There was hardly more small-pox there than in peace-time. Dr. Sobernheim's paper also refers to the usual objections to vaccinations; he appreciates the protection enjoyed by Switzerland owing to the efficiency of vaccination in Germany; nevertheless he has important recommendations for Switzerland, which are well worth the notice of legislators here. Notes are added about the method of spread of infection, and about recent research into the nature of small-pox infection. Altogether a notable epidemiological contribution, if only for its appreciation of a fact imperfectly understood on this side of the Channel—namely, how much the work of army medical officers protected the civil population at home.

REFORM IN THE LAW OF DEATH CERTIFICATION.

RECENTLY in the House of Commons Mr. John Davison asked the Minister of Health whether, in connexion with his consideration of intended reforms in the present law of death certification, he would take note of the desirability of providing that no medical practitioner should certify a death without having first inspected the body, and that all deaths occurring suddenly after operations or vaccination or inoculation or drug injections should be reported to the coroner by the medical practitioner in attendance. To this question Dr. Addison replied that the points referred to should be considered. Doubtless, Mr. Davison meant more than his question implied. We are not aware that medical men do "certify *deaths*" without first inspecting the body; it is certainly not desirable that they should. On the other hand, that no medical man should certify as to the *cause* of death of a person under his care, whose death is reported to him, without satisfying himself by inspection that death has occurred, is quite another matter. At present, of course, a doctor is prohibited by statute from making any charge in respect of a certificate of the cause of death; but, if the State desires to cast further statutory duty and responsibility upon medical men, the discharge of such duty and responsibility will not be acceptable—we must speak frankly—unless the State provides for just remuneration, in certain cases at least, and removes the present proscription of fees from persons who are in a position to pay them.

The second portion of the question asked by the honourable Member for Smethwick contains a suggestion which, if carried into effect, would entail consequences that can hardly be foreseen by him. We do not envy the draftsman called to define the terms "suddenly" and "after," in this connexion, and if, as would appear probable, it is the desire of the honourable Member to impose some form of check on the professional treatment of persons undergoing it, we do not see why he does not suggest that *all* deaths occurring suddenly after treatment of any kind by a qualified medical man should be reported to the coroner, just as all sudden deaths occurring without treatment are now so reported. True, we should require many more coroners and should have many more inquests. But, in all seriousness, is it not obvious, if special surgical and medical procedures, when followed by the death that they have perhaps been undertaken to avert or postpone, are to involve, if not in every case a formal inquest, at least a coroner's officer's inquiry, that the public generally will be averse from sanctioning these procedures, and that doctors will hesitate to act without express sanction? We do not fear that any hasty or ill-considered legislative efforts will be initiated by the present Minister of Health; but there seems need for the public to be instructed, and, in the absence of such instruction, unwise or even foolish public demands are apt to become so insistent that ultimately "something" is "done" that would better have been left undone.

CAROTINÆMIA.

UNDER this title Dr. A. F. Hess and Dr. V. C. Myers,[1] of New York, describe a systemic pigmentation caused by the introduction of an excess of carotin in the food. The colouration is not confined to the face, but involves to a less extent the entire body, being most evident on the palms of the hands, which show also distinct signs of desquamation. The sclerotics are not at all affected. The urine is amber, and the stools are normally yellow. The two children in whom this new clinical picture was observed were receiving a daily ration of carrots in addition to new milk and cereal. On omission of the carrots from the diet the skin gradually lost its yellow colour, and in the course of some weeks regained its normal tint. The discolouration of the skin was accompanied by a similar yellow tinging of the blood serum and the plasma, the pigment in the blood being identified as carotin. As this substance is a constituent of almost all vegetable foods, the writers are of opinion that carotinæmia is not a rare occurrence, but has probably been frequently overlooked, confused with mild grades of icterus, or attributed to some obscure metabolic disturbance. They found that when carotin was injected subcutaneously, or given by mouth, the pigment appeared rapidly in the urine. This occurrence is of interest in view of the fact that there is a general tendency to regard urinary pigments as formed solely from bile or its derivatives.

THE VENTILATION OF SUBMARINES.

BOTH aeroplanes and submarines have introduced new physico-medical problems, or rather they have made of old physical problems matters of great medical importance at the present time. Two or three articles have appeared during the last 18 months in the French medical press on submarine hygiene, the most recent being a contribution by Dr. L. Brodier in the *Paris Médical* for Dec. 20th, 1919. The French submarines vary considerably in size, but an average air capacity appears to be about 400 cubic metres, which allows roughly 12 cubic metres per man. On a smooth sea, when the submarine is riding on the surface, a moderately efficient ventilation is afforded by the port-holes, but should the sea be at all choppy these openings must all be closed and an auxiliary system of ventilation becomes necessary. The American vessels have a ventilation pipe accompanying the periscope. The French submersibles are fitted with two "air sleeves." Fresh air is sucked through one and foul air expelled through the other by means of electric fans. When the boat is submerged new problems arise. Communication with the atmosphere is excluded. In addition, hydrogen evolved from the accumulators cannot be carried away, and as its proportion in the atmosphere rises the danger of explosion is increased—8 to 10 per cent. will be detonated by a spark from the motors. Other gases more directly poisonous are also contributed by the electric apparatus, as when sea-water coming into contact with a current is electrolysed, with the formation of chlorine. To complete the medley of evil odours it is only necessary to remember that all life must be carried on in this confined space. It is comforting to learn that, according to the researches of Kress, there are fewer bacteria present in this mixed atmosphere under water than when the boat is fully ventilated on the surface. The replenishment of oxygen is found to be one of the least of the difficulties to be overcome; 16 per cent is held to be the lower limit for oxygen content of the air. In the *Daphné* (380 cubic metres for a crew of 33 men) the oxygen content was found to be still 17 per cent. after a dive of 16 hours without oxygen replenishment. The elimination of carbon dioxide and poisonous gases is a more serious difficulty. In the experiment just quoted the *Daphné's* CO_2 content was found to have risen to 1·6 per cent. in six hours only, the limit being considered as 3 per cent. Many of the methods used for purifying the atmosphere are still kept secret by the various powers, but one or two are disclosed in Dr. Brodier's paper, the German and Italian methods being described in some detail. The principal in each case is to pass the vitiated air over some chemical mixture which will absorb the impurities. Arsenuretted hydrogen is a special danger. The English accumulators are made of selected metal from which every trace of arsenic has been eliminated. In addition, each chamber is adorned with paper treated with bichloride of mercury to detect traces of this dangerous gas in the atmosphere. The French meet the danger by including potassium permanganate amongst the chemicals over which the impure air is passed. The danger of fire from explosion would appear to be ever present, and, in the German submarines at least, fire extinguishers are furnished in every compartment.

---

OLD-AGE PENSIONS IN 1920.

THE increased price of the necessaries of life rendered imperative some increase in old-age pensions, which were originally fixed by an Act of Parliament passed in 1908, and the opportunity has been taken to introduce a few administrative improvements to a measure already amended in 1911. In the financial circumstances produced by the war it could hardly be expected that an augmentation would be granted upon a scale that would substantially improve the situation of pensioners as compared with that prevailing before August, 1914, but the maximum pension is now doubled, and allowance is made for the diminished purchasing power of any income already enjoyed by the recipient, the improved pension taking the place of the weekly 2*s.* 6*d.* recently given as an additional allowance. Under the old scheme the full weekly pension of 5*s.* was given where the yearly means of the pensioner did not exceed £21, and no pension was allowed where they exceeded £31 10*s.* Under the new scheme a sum of 10*s.* is allowed where the existing means do not exceed £26 5*s.*, and the claim to a pension on a sliding scale exists up to the point where there is an independent income exceeding £49 17*s.* 6*d.* The sliding scale for those having incomes between the lowest and highest above mentioned is proportionate, the amounts being between £26 5*s.* and £31 10*s.*, eight shillings per week; £31 10*s.*–£36 15*s.*, six shillings; £36 15*s.*–£42, four shillings; £42–£47 5*s.*, two shillings; and £47 5*s.*–£49 17*s.* 6*d.*, one shilling. The disqualifications attaching to the receipt of poor relief are reduced, and are stated in a circular issued by the Ministry of Health, the department now responsible, to explain these and various other changes effected by the Act of 1919, now in force.

> "A person will not in future be disqualified for receiving or continuing to receive an old-age pension by reason of the receipt of outdoor relief. A person who has become an inmate of any workhouse or other Poor-law institution will be disqualified for receiving, or continuing to receive, a pension while he is an inmate, subject, however, to the proviso that a person who enters a Poor-law institution for the purpose of obtaining medical or surgical treatment, will not, during a period of three months, if he so long continues to require such treatment, be disqualified on the ground only that he is an inmate of a Poor-law institution."

It must certainly be admitted that the Acts of 1911 and 1919 have considerably improved the original law under which a claimant was once refused a pension who had been an inmate of an infirmary, and had been removed from it to the workouse at the request of the doctor under whose care she was, in order to make room for urgent cases, and who, after being treated at the workhouse for seven or eight weeks, was discharged cured. Another claimant, when the Act of 1908 came into force, was refused a pension because while he was in a hospital in December, 1908, his wife had had to obtain outdoor relief! Mr. H. J. Hoare, in his small book on Old Age Pensions,[1] from which we have taken the above examples, proposed the refusal of pensions to persons so dirty and verminous as to suggest their inability to exist with reasonable decency upon the pension. The sum allowed is still so small that old people not able to obtain any addition to it will hardly be able to support themselves, but apparently they are still to be left to select for themselves the moment when they will give up the unequal struggle against penury and its results. Mr. Hoare in 1915 could find few recommendations to make for bettering the existing Acts, and having considerable experience of their administration in the neighbourhood of London was of the opinion that they worked smoothly and well. The recent amendments are indeed not likely to be improved upon until the Treasury finds itself able to sanction a considerable increase in expenditure, a consummation not likely to be realised for some time. It is possible, however, to hope for, rather than to predict, an automatic amelioration of the lot of the old-age pensioner through an eventual fall in some, at least, of the prevailing prices.

JUVENILE EMPLOYMENT.[1]

THE period covered by this report was, perhaps, the most critical one of the war, when the problem was rather the extent to which all workers could contribute to the national effort than the way in which industrial conditions could be modified to benefit the juvenile worker. Whilst the demand for boy and girl labour was greater than in normal times, the openings offered were inferior; the employment available, notably munition work and clerical work in Government departments, did not offer any training for the future. The use of schools as hospitals necessitated the occupation of other school buildings by two schools, so that the children could only be accommodated half of each day, with the result that many of the children filled in the other half with employment. The system of testing applicants for certain employments plainly showed that the school leaver from a half-time school was inferior in ability and general intelligence to children who had been attending a full-time school. Now that the bad times are over the Cardiff Education Committee hope that much can be accomplished in the training of juveniles for crafts and occupations by taking individual trades or groups of kindred trades and thoroughly overhauling the system, standardising wages and conditions, and making apprenticeships more attractive as compared with casual and cul-de-sac employments. The children from the poorer parts of the city display an amazing lack of knowledge of anything outside their own restricted district. To remedy this defect in a measure arrangements have been entered into with a number of employers for small parties of senior pupils to be conducted round works and factories. Apart from the question of employment, the educational value of such visits is considerable.

The neglected boy who spends most of his leisure time in the streets constitutes a special problem. Two of the care committees of the district have been able to organise boys' clubs, which have proved successful in dealing with this class of boy. In connexion with the larger club it is proposed to organise a working boys' home, especially for boys who have come to Cardiff to find work or to secure a berth at sea. Unfortunately, during the period under report, despite efforts made, no progress can be reported in the direction of increasing the facilities for training boys for the sea. Yet such a scheme would eventually restrict the number of foreigners employed in our mercantile marine and promote a freer and more ready recruitment of boys into a useful and profitable occupation; boys who now often become ne'er-do-wells would have a chance of developing into useful members of society. The work of the school medical service in Cardiff has proved very useful in connexion with juvenile employment by reason of the valuable information given for every boy and girl dealt with, and the facilities available for special advice and examination of difficult individual cases. The need of work on behalf of children after leaving school is pressing everywhere; obviously in Cardiff good work has already been done by voluntary effort guided by expert organisation, and the directions in which this work can, and should, be extended are indicated.

ANTHRAX IN BRUSHES.

By a provision of the Factory and Workshops Act of 1901 cases of industrial infection with anthrax were made notifiable to the chief inspector of factories at the Home Office. Dr. T. M. Legge, in his Milroy lectures four years later, dealt with 261 cases and 67 fatalities which had come before his official notice up to 1905. Of these, 70 cases with 17 deaths had to do with infection from hair and bristles. This particular source of infection has been attracting increasing attention since the incrimination of the shaving brush. The first case in which the shaving brush was definitely proved to be the lethal agent was recorded by Dr. R. R. Elworthy, then pathologist to the West London Hospital, in our own columns (Jan. 1st, 1916). At the instance of the Local Government Board a prolonged investigation was made by Dr. F. J. H. Coutts, which appeared in a volume of Reports on Public Health Subjects in 1917. Dr. Coutts found that brushes of home manufacture were implicated, as well as those imported from Canada, America, and Japan. Administrative action was taken upon this report, but the Ministry of Health announce that cases of anthrax are still occurring in this country, two of which have recently proved fatal. In a substantial proportion of the cases infection has been traced to new shaving brushes imported from Japan. Samples taken from several consignments of Japanese brushes have been found to contain anthrax spores. As several consignments of these brushes have already been distributed it is impossible for steps to be taken to discover them all. Intending purchasers are therefore advised by the Ministry to ask for an assurance that the brush offered for sale is not one of a batch recently imported from Japan. Any person in doubt as to a brush in his possession may diminish the risk by adopting the following procedure, although the Ministry does not suggest that any such process affords a certain safeguard against infection:—

> Thoroughly wash the hair of the shaving-brush with soap and warm water, to which a little washing soda has been added, rinse in warm water, and then immerse for one hour in a disinfecting solution consisting of two tablespoonfuls of formalin in half a pint of water. The disinfecting solution should be at a temperature slightly above the body heat. After removal from the solution the brush should be allowed to dry before use. In carrying out the above, care should be taken not to allow the hair of the brush to come in contact with the hands.

In the meantime, and until infected shaving brushes have been excluded from the market, it may be remembered with satisfaction that a brush is by no means an indispensable tool for a successful shave.

THE CAMBRIDGE DIPLOMA IN RADIOLOGY.

Radiology is gradually taking up the position in the practice of medicine which its importance requires. In commenting in The Lancet of Oct. 25th, 1919, upon Dr. A. E. Barclay's presidential address before the Section of Electro-Therapeutics of the Royal Society of Medicine we anticipated the practical recognition of this fact by one of the older universities. On Jan. 19th next, courses begin at Cambridge for the new diploma in radiology and electrology, set up by Statute on June 17th of last year. The course of study for the diploma extends over a period of six months or more, and includes both lectures and clinical instruction. The lecture course in Part I. consists of physics and electro-technics with photography; in Part II., radiology and electrology, in each case with special reference to both diagnosis and therapy. Six months clinical experience is required in the electrical department of a hospital recognised by a committee of the State Medicine Syndicate; for this purpose all the larger London teaching hospitals are eligible, as well as the Cancer and Consumption Hospitals at Brompton. Apart from examination, the diploma may also be granted to a medical practitioner of not less than ten years' standing who has been engaged for at least half that time in the practice of medical radiology at a recognised hospital, on presentation of a dissertation which may include work already published. Similar courses will be given in London and other centres as the demand for them arises. The actual arrangements, as far as at present fixed, are noted in another column. It is time that the subject, too long the playground of empiricism, should come under the discipline of a teaching faculty.

The offices of Epsom College have been transferred from 37, Soho-square, W., to 49, Bedford-square, W.C. 1, owing to the expiration of the lease of the former house.

The compulsory notification of cases of acute encephalitis lethargica and acute polio-encephalitis, in force since January, 1919, has been extended until further notice by order of the Minister of Health, dated Dec. 31st, 1919.

The arrangements are now far forward for the formation of university units at two more metropolitan teaching hospitals—namely, St. Thomas's and University College. The appointments made in these connexions have for long been an open secret. At St. Thomas's Hospital Dr. E. H. Starling, professor of physiology at University College, becomes the director of the medical element, a capital appointment because it emphasises the close relations that physiology possesses with modern medicine. At this hospital Sir Cuthbert Wallace, surgeon to the hospital, will be the director of the surgical element. Mr. C. C. Choyce's name is given as the director of the surgical element at University College Hospital, where Dr. T. R. Elliott will be the director of the medical element.

INDEX TO "THE LANCET," Vol. II., 1919.

The Index and Title-page to Vol. II., 1919, which was completed with the issue of Dec. 27th, will be published in The Lancet of Jan. 17th.

THE DYING-OUT OF NATIVE RACES.

By W. H. R. RIVERS, M.D., F.R.S.

(Concluded from p. 44.)

European Influence on Native Customs.

I COME to a more serious cause when I consider European influence upon native customs. I begin with one which excites perennial interest whenever native welfare is discussed. Before the advent of Europeans many Melanesians went wholly nude or wore only garments, if they can be so called, which fulfilled neither of the two chief purposes for which the clothing of civilised people is designed. In other parts the native clothing consisted of petticoats, loincloths, or other simple garments thoroughly adapted to the necessities of the climate. One of the first results of European influence was the adoption of the clothing of the visitors, and clothes were adopted in such a manner as to accentuate the evils which they necessarily brought with them. The Melanesian is not really uncleanly. He bathes frequently, and where he preserves his native mode of clothing his ablutions are amply sufficient for cleanliness. When he wears European garments he fails to adopt measures, such as the frequent change of clothing, which then become necessary. He continues to bathe in his clothes, and instead of changing his garments frequently wears them continuously till they are ragged, and even when new clothing is obtained it is put on over the old.

It is a great mistake, often made, to blame the missionaries for this use of foreign clothing. It is true that its use was directly encouraged by the early missionaries, but this encouragement was unnecessary. To the native, trousers and coats are the distinctive marks of the white man, and nothing short of prohibition could have prevented their use. Where we now see the missionaries to have been at fault is that they did not recognise the evil of the innovation and set themselves steadily to minimise it, and insist upon attendance to the elementary principles of the hygiene which the use of clothes involves.

At the present time the influence of missionaries is steadily directed to this end. Having been privileged to live among missionaries of different schools of thought in Melanesia, I can testify that no subject is more frequently discussed and more thoroughly and anxiously considered than how to lessen the use and njurious influence of European clothing.

Another modification of native custom, which is less widely recognised, but in my experience quite as much in need of consideration at the present time, is housing. The native Melanesian house is usually rainproof and of good proportions, while owing to its mode of construction it is well ventilated and thoroughly adapted to the climate. Instead of being content with houses of similar construction or with houses of the kind used by Europeans living in other tropical countries, settlers have built houses with impermeable walls and very imperfect means of ventilation. These have in some cases been copied by the natives or even built by the missionaries for the use of their followers. Such buildings might have been specially devised for the propagation of tubercle, and if they are allowed to be built will certainly increase the already far too heavy ravages of this disease.

The modifications of housing and clothing which I have just considered touch especially the material side of life. I have now to consider a number of modifications and interferences with native custom which I believe to have been quite as important, if not even more important, in the production of native decadence. When Melanesia became subject to Europeans, magistrates and missionaries were sent to rule and direct the lives of the people. They found in existence a number of institutions and customs which were, or seemed to them to be, contrary to the principles of morality. Such customs were usually forbidden without any inquiry into their real nature, without knowledge of the part they took in native life, and without any attempt to discriminate between their good and bad elements. Thus, in the Solomon Islands, the rulers stopped the special kind of warfare known as head-hunting, without at all appreciating the vast place it took in the religious and ceremonial lives of the people, without realising the gap it would leave in their daily interests, a blank far more extensive than that due to the mere cessation of a mode of warfare. Again, in Fiji, the custom according to which the men of the community slept apart from the women in a special house, a widespread custom in Melanesia, seemed to the missionaries contrary to the ideals of the Christian family, and the custom was stopped or discouraged without it being realised that it formed a most effectual check on too free intercourse between the sexes.

In the New Hebrides, again, the missionaries put an end to, or where they did not destroy treated with a barely veiled contempt, a highly complicated organisation arising out of beliefs connected with the cult of dead ancestors. In some cases it was apparently enough that the institution, with all its elaborate ceremonial, was heathen and prejudiced church attendance, while elsewhere stress was laid on occasional revels and dances which gave opportunity for licence. It was not recognised that in forbidding or discouraging without inquiry they were destroying institutions which had the most far-reaching ramifications through the social and economic life of the people. I have called attention to this subject elsewhere in an essay on the Government of subject peoples in the Cambridge collection of essays, entitled "Science and the Nation." I have there pointed out that if these and similar institutions had been studied before they were destroyed or discouraged, it would have been found possible to discriminate between those features which were noxious and needed repression or amendment and those which were beneficial to the welfare of the community. Even if their destruction were still deemed necessary, something could have been done to replace the social sanctions of which the people were thus deprived. The point I wish to emphasise is that through this unintelligent and undiscriminating action towards native institutions the people were deprived of nearly all that gave interest to their lives.

Loss of Interest in Life the Cause of Native Decadence.

I have now to suggest that this loss of interest forms one of the reasons, if indeed it be not the most potent of all the reasons, to which the native decadence is due. It may at first sight seem far-fetched to suppose that such a factor as loss of interest in life could ever produce the dying-out of a people, but my own observations have led me to the conclusion that its influence is so great that it can hardly be overrated, and I venture, therefore, to consider it at some length.

When you inquire of those who have lived long in Melanesia concerning the illness and mortality of the natives, you are struck by the frequency of reference to the ease with which the native dies. Over and over again one is told of a native who seemed hale and well until, after a day or two of some apparently trivial illness, he gives up the ghost without any of the signs which among ourselves give ample warning of the impending fate. A native who is ill loses heart at once. He has no desire to live, and perhaps announces that he is going to die when the onlooker can see no ground for his belief.

The matter becomes more easy to understand if we consider the ease with which the people are killed by magic, or as the result of the infraction of a taboo. The evidence is overwhelming that such people as the Melanesians will sicken and die in a few hours or days if they believe that an enemy has chosen them as the victim of his spells, or that they have, wittingly or unwittingly, offended against some religious taboo. If people who are interested in life and do not wish to die can be killed in a few days or even hours by a mere belief, it becomes much more easy to understand that a people who have lost all interest in life should become the prey of any morbid agency acting through the body as well as through the mind. It is this knowledge of the enormous influence of the mind upon the body among the Melanesians and other lowly peoples that first led me to attach so much importance to loss of interest as the primary cause of their dying out. Once this belief has been formulated there is seen to be much definite evidence in Melanesia to support it.

Certain islands and districts of Melanesia show a degree of vitality in striking contrast with the rest. These exceptional cases fall into two classes: one includes those islands or parts of islands where the people have so far been fierce and strong enough to withstand European influence. There are still parts of Melanesia which as yet the footprint of the white man has not reached, and others where, after successful encounters with punitive expeditions, the people still believe themselves to be a match for the invader. Here the old zest and interest in life persist and the people are still vigorous and abundant.

The other group of peoples who show signs of vitality are those who have adopted Christianity, not merely because it is the religion of the powerful white man, but with a whole-hearted enthusiasm which has given them a renewed interest in life. Here the numbers are increasing after an initial drop. Christianity and the occupations connected with it have given the people a new interest to replace that of their indigenous culture, and with this interest has come the desire to live.

The special point I wish to make to-day is that in my belief interest in life is the primary factor in the welfare of a people. The new diseases and poisons, the innovations in clothing, housing, and feeding, are only the immediate and more obvious causes of mortality. It is the loss of interest in life underlying these more obvious causes which gives them their potency for evil and allows them to work such ravages upon life and health.

Influences Decreasing the Birth-rate.

I can now pass to the second of the two groups of influences by which a people decline in number. I have so far dealt only with those which increase the death-rate. I have still to consider those which produce decline by diminishing the birth-rate. I must begin by stating briefly the evidence that this factor has played and is playing a part in the dying-out of the Melanesians. Here, as in the case of the death-rate, I can offer you no positive statistics derived from a record of births. My evidence is chiefly the result of a means of inquiry adopted originally for purely scientific purposes. When in Torres Straits with Dr. Haddon 20 years ago I discovered that the people preserved in their memories with great fidelity a full and accurate record of their descent and relationships. It was possible to collect pedigrees so ample in all collateral lines that they could serve as a source of statistical inquiry into such features as the average size of a family, infant mortality, and other subjects which furnish the basis for conclusions concerning the fluctuations of population. I have found this interest in genealogy wherever I have worked, and the collection of pedigrees has always formed the basis of my inquiries. In Melanesia this instrument shows conclusively that the fall in numbers is due quite as much to decrease of the birth-rate as to increase of the death-rate. I cannot here go into the evidence in any detail; I must be content with an example from the people of Vulua in Santo, a people whose decline has been mentioned as having been watched by Mr. Bowie during the last 20 years.

About 80 years ago, when Santo was comparatively untouched by outside influences, a man named Rathati married. He had four children, whose marriages gave Rathati 15 grandchildren, of whom my informant, a man verging towards middle life, was the sole survivor. Of these 15 grandchildren, ten grew to adult age and married, but only two of these unions produced offspring. One married couple had a boy who died in infancy, while another had three children. These three children, the great-grandchildren of Rathati, married, but none had offspring, so that a family, once rapidly growing in numbers, closed its career with a monotonous record of sterile marriages.

A similar frequency of childless marriages occurs in the pedigrees of other islands where the population is decreasing, not only in the New Hebrides, but also in the Solomons, showing definitely that lowered birth-rate must rank with enhanced death-rate as at least an equally important factor in the dying-out of the people.

Voluntary Restriction of Birth-rate.

I need only consider briefly the agencies to which this decline is due. It is well known that certain forms of venereal disease tend to produce sterility, and it is noteworthy that the dying-out of the people of Vulua is ascribed by their neighbours to the ravages of such disease brought with them by returning labourers from Queensland. There is little doubt, however, that if we take Melanesia as a whole, causes of this kind are trivial or of slight importance as compared with voluntary restriction. Throughout Melanesia the people are acquainted with various means of producing abortion, and practise measures which they believe to prevent conception, and processes of this kind form the main agencies in lowering the birth-rate. We have here only another effect of the loss of interest in life which I have held to be so potent in enhancing mortality. The people say themselves: "Why should we bring children into the world only to work for the white man?" Measures which before the coming of the European were used chiefly to prevent illegitimacy have become the instrument of racial suicide.

Reaction to New Interests.

It is satisfactory that before I leave this subject I am able to point to a brighter side. I have already said that in certain parts of Melanesia the downward movement in numbers has been arrested, and that the people now show signs of growth. I mentioned also that this was occurring especially in islands where the people have really taken to heart the lessons of their Christian teachers. I collected pedigrees from several such islands, and they tell a tale vastly different from the miserable record of Vulua. A man of the little island of Makura named Masosopo, who married about 70 years ago, had three children and nine grandchildren, and there are already 14 great-grandchildren, with a prospect of more to come, a striking contrast with the impending disappearance of the Vulua family. A couple who married about the same time in Nguna now have living and thriving 23 descendants, while in other islands I have records of families of from 8 to 10 in number.

The teachings of the missionaries concerning the evils of racial suicide have probably contributed to this recovery, but there is little doubt that its chief cause has been that their new religion has given to the people an interest in life which has again made it worth while to bring children into the world.

Effect of Labour Traffic.

Those here who know anything of Melanesia and its circumstances will have wondered why I have so far said nothing about the cause of depopulation which might well be put before all others for the potency of its evil influence. I have so far left the labour traffic on one side, partly because, had I once started upon it, I should have been tempted to devote the whole lecture to its far-reaching and deeply penetrating influence. My chief reason, however, was that it has seemed better to choose those of the circumstances of Melanesia which illustrate general problems and to leave on one side a factor which, though peculiarly potent in the case of Melanesia, is fortunately of far less general application. It would, however, be quite unfitting to leave the labour traffic wholly on one side.

In the first place it is well that we are able to distinguish between the traffic as it was and as it is. It would be difficult to exaggerate the evil influence of the process by which the natives of Melanesia were taken to Australia and elsewhere to labour for the white man. It forms one of the blackest of civilisation's crimes. Not least among its evils was the manner of its ending, when large numbers of people who had learnt by many years' experience to adapt themselves to civilised ways were, in the process of so-called repatriation, thrust back into savagery without help of any kind. The misery thus caused, with the resulting disaffection, not only underlies most of the open troubles in the recent history of Melanesia, but by the production of a state of helplessness and hopelessness has contributed as much as any other factor to the decline of the population.

I must not, however, dwell on the crimes and mistakes of the past. My object to-day is to call attention to existing evils in the hope that they may be remedied before it is too late. At the present time Melanesians are only recruited as labourers to work within the confines of Melanesia, and both the recruitment and the conditions of labour are subject to Government control. Its grosser evils have been removed, at any rate in those parts of Melanesia which are wholly governed by Great Britain. But, however closely and wisely the traffic is controlled, the removal from their own homes of the younger men of a declining population is not a factor which can tend to arrest the decline or convert it into a movement in the opposite direction. Even in its vastly improved form, and limited to Melanesia though it be, the labour traffic continues to act as a cause of depopulation. Not only does it act directly by taking men away from their homes when they should be marrying and producing children, but it also fails in that it provides no real basis for that zest in life upon the importance of which I have already so fully dwelt. Other evils are that the traffic as at present conducted tends to spread disease and to undermine an influence which I believe to be at the present time the most potent for good in Melanesia, the work of the missionaries. I cannot stay to point out exactly how the traffic works to the detriment of native progress. I must be content to state again that aspect which brings it into relation with the main thesis of this lecture. It fails to give the people that interest in life which I believe to form the most essential factor in maintaining the health of a people.

Restoration or Replacement of Interests as the Sole Remedy.

I have dwelt at such length on the nature and causes of the decline of the population of Melanesia that I have left myself but little time to consider the treatment for the malady from which the peoples of this region are suffering. I make no apology, however, for this. One of my teachers in medicine, Dr. Gee, used to quote the saying[1]: "Medicine has three parts; the first is diagnosis; the second is diagnosis; and the third is diagnosis." This saying is just as true of the medicine of society as of the medicine of the individual. By diagnosis Dr. Gee did not mean, nor do I mean, the process by which we give a name to a disease. The word connotes the whole process by means of which we come to understand the nature of each individual case of disease, and analyse into its elements the complex web of agencies by which the morbid state has been produced. Taken in this wide sense, this lecture has thus far dealt wholly with the process of diagnosis. The more complete this diagnosis, the more obvious becomes the treatment and the less necessary to go into it at length. If I am right in my diagnosis it is easy to see the general lines which treatment should take.

I shall pass with a mere mention those lines of treatment, dictated by the ordinary principles of hygiene, by means of which faults of clothing, housing, and feeding may be remedied, and shall confine my attention to the factor which I believe to stand first and foremost among the causes of the dying-out of the Melanesian—the loss of interest in life from which at present he is suffering.

The main problem of treatment is how far it is possible to restore the old interests or maintain them where they have not yet been destroyed, and how far they must be replaced by others. As I have already mentioned, there are still parts of Melanesia where the old life persists with but little change, and it would be an interesting experiment to see how far it is possible in these places to maintain the old interests and make them the foundation on which to build a culture which would not conflict with that of the people who have become their rulers. I have dealt with this subject in the essay on "The Government of Subject Peoples," already mentioned. I will only reiterate here the main conclusion of that essay, that any attempt to govern a people even partially on the lines of their own culture demands knowledge on the part of the rulers, knowledge which at present they do not possess, and in general make no effort to attain.

I will, therefore, only refer to-day to the second alternative, how we may replace old interests by new. To one such new interest, that of religion, I have already referred. The old life of the people was permeated through and through by interests of a religious kind, based on a profound belief in continued existence after death and the influence of the dead upon the living. Experience shows that Christianity is capable of giving the people an interest in life which takes the place of that due to their indigenous religion. Man cannot or should not, however, live upon religion alone. It is necessary to find something to take the place of the old economic interests also. At the present time, throughout the greater part of Melanesia, the people either give their work wholly for others on plantations or grow just the few coconuts which are necessary to produce certain luxuries, such as calico and tobacco, gramophones and tinned meat.

The chief need in Melanesia is to give the native a more real interest in the economic development of his country. The Melanesian is a keen trader, and there are cases in the New Hebrides in which he has shown much ability when he has entered as an ordinary trader into competition with the European. There is no question that if he were given a fair chance he could take an important part in any organisation which had as its object the encouragement of native industry. Until recently the missionary societies of Melanesia have made no attempt at industrial development, either to encourage the old industries or to introduce new, and the Government has done even less in this direction. The only neighbouring region where anything of the kind has been done is in Torres Straits, where "The Papuan Industries Company" has endeavoured, with a fair degree of success, to give to the natives that share in the management of the industries of their country which is the best means of bringing back the old interest and zest in life. In other parts of the world, and pre-eminently in West Africa, such movements have had the most striking success, and there is no reason why the success should not be as great in Melanesia.

Among the many problems which await our rulers when they are able to turn their thoughts from more pressing matters is the industrial development of the tropics. For this purpose labour is necessary, and experience shows that this labour comes most naturally and most profitably from those in whom long generations have brought about a physical development adapted to tropical conditions. The main object of this lecture has been to draw attention to a psychical aspect of the problem. The indigenous inhabitants of tropical countries will not thrive, they will in some cases, as we have seen, not even live, unless they are interested in life, and this factor of interest must be taken into account by those upon whom falls the task of organising the development of tropical industry.

Though this utilitarian aim must of necessity be prominent in the organisation of tropical industry, there is another reason which should compel us to give to the natives of tropical countries a real interest in their own social and economic development. If we in the late war gave our best blood on behalf of oppressed nationalities and in the cause of freedom, it should be equally impossible to pass over the rights of such peoples as the Melanesians. I have tried to show in this lecture that the fundamental right, the right to exist, is being threatened in their case. If there is any truth in this view the peril may be averted, and averted by giving back to them that interest in life which we have, often unwittingly, destroyed.

Mr. G. S. A. Waylen has resigned the post of district medical officer and workhouse medical officer of the Devizes Union after 30 years' service.

---

[1] I have been unable to discover to whom this aphorism is originally due.

THE NEED FOR REWARDS FOR MEDICAL DISCOVERY.

THE following report (dated Dec. 22nd, 1919) has been presented by the Joint Committee of the British Medical Association and the British Science Guild on awards for medical discovery :—

1. *Definitions.*

Medical discovery may here be defined as being: (1) The ascertainment of new facts or theorems bearing on the human body in health, and the nature, prevention, cure, or mitigation of injuries and diseases of human beings. (2) The invention of new methods or instruments for the improvement of sanitary, medical, and surgical practice, or of scientific and pathological work.

2. *Reasons for Rewarding Medical Discovery.*

These are: (1) To encourage medical investigation. (2) To discharge a moral obligation incurred by the public for its use of private effort.

3. *Various Possible Types of Rewards.*

(1) Titles and honours given by the State, by universities, and by other public bodies. (2) Prizes and medals. (3) Patents. (4) Promotions and appointments. (5) Pecuniary awards by the State.

4. *General Principles of Assessment.*

It will probably be agreed that in the interests of the public all medical discoveries should, if possible, receive some kind of acknowledgment or recompense. But in view of the very variable conditions, nature, and effects of particular investigations, it will often be difficult to assess the kind of recompense most suitable for each. In the first place, a distinction should be drawn between *compensation* and *reward*. By *compensation* is meant an *act of justice* done for the purpose of reimbursement of losses; by *reward, an act of grace* in appreciation of services rendered.

The following different cases should next be considered :—

(A) Discoveries involving pecuniary or other loss to an investigator, either by direct monetary sacrifice, or by expenditure of time, or by diminution of professional practice, without corresponding pecuniary gains. A great example is that of Edward Jenner, who occupied himself so closely with the investigation of vaccination against smallpox that he lost most of his medical practice and also considerable sums in expenses. The plea for compensation in such cases is unanswerable; and in 1802 and 1807 Parliament fully acknowledged its obligations under this head by giving Jenner compensation in two sums of £10,000 and £20,000.

(B) Discoveries which have increased the professional emoluments of the investigator by enhanced practice or other means. Such are, frequently, improvements in surgical operations or medical treatment, which lead to increased practice. Another case is that of serums, &c., which may have been protected and put on the market. Here compensation cannot be demanded and pecuniary awards may be generally held to be unnecessary. On the other hand, honours are often, and justly, bestowed upon such work.

(C) Discoveries which involve neither gain nor loss to the investigator. This class includes most of the good, and sometimes great, clinical, pathological, and sanitary discoveries achieved in the world. Here also compensation can scarcely be demanded, and honours are already often given; but pecuniary awards should be sometimes bestowed as an act of grace when the value of a discovery to the public (or to a government) greatly exceeds the emoluments of the investigator; and this principle should hold even in the case who were directly paid for undertaking the researches which led to their discoveries—especially when such payment was (as usual) small, and the resulting discovery great.

The following particular cases, which sometimes occur, should be specifically noted: (1) Men who have refused lucrative posts in order to complete their researches. (2) Men who have refused to protect their work for fear of limiting its application. (3) Men who have carried out investigations for governments for little or no payment, on patriotic grounds.

The following considerations must generally be borne in mind :—

(*a*) Honours (which are always much esteemed) are usually given as much (or more) for clinical success as for medical discoveries, though the latter possess a far wider influence and application than do the former.

(*b*) When given for clinical work or for discoveries under Class B, honours often confer distinct pecuniary advantages by enhancement of practice, but for discoveries under Classes A and C they have no such effect, and cases are on record where they tend to reduce emoluments by unfitting recipients for certain posts.

(*c*) Most people enter the medical profession (at considerable expense) not only from altruistic motives, but also to make a living; and it is usually only at a later period that they take up scientific investigation—either from a sense of duty, or from predilection, or merely because a good opportunity offers. When, therefore, a man finds that his scientific work, however successful and important it may have been, has actually yielded him less emolument than he might have obtained from ordinary clinical work, he feels naturally discouraged; and his experience prevents young men of ability from following his example, and therefore tends to check the prosecution of studies which are of the highest value to humanity.

(*d*) In the public interest, then, this Committee begs to insist upon the principles: (1) That no medical discovery should be allowed to entail financial loss upon him who has made it. (2) That the compensation or reward which he deserves should be assessed as being equal to the difference between the emoluments which he has actually received and those which a successful clinician might have received in the same time.

This is obviously the principle which was accepted by Parliament in the case of Jenner in 1802 and 1807.

Additional reasons for insisting upon this principle are: (1) That few medical discoveries are patentable. (2) That such discoveries seldom give good grounds for promotion or for administrative appointments in the public services.

5. *Particular Assessments.*

Whether a particular discovery should receive a large or small assessment will depend not only on the considerations given above, but also on the following :—

(1) *Width of application.*—For example, the work of many of the older anatomists, physiologists, and parasitologists, of Pasteur, and of investigators of immunity, have affected most recent discovery. Discoveries on widespread diseases, such as the work of Lister, of Laveran, and of Koch, are often, though not always, more important than those on more limited maladies.

(2) *Difficulty of the work done.*—For example, the solution of a difficult problem requires more study and also more time and cost, and therefore deserves more recompense than a lucky chance observation.

(3) *Immediate practical utility.*—A strong plea for State remuneration can be made on behalf of cases of this kind, unless they come under Class B. It is strange that at present they never receive it, while academical recognition is also often not forthcoming for them.

(4) *Scientific importance.*—Discoveries which are not of present practical utility may become so at any moment, and should obviously be included in the scheme, if they are sound and of wide application.

Medical discoveries made by persons who do not themselves belong to the medical profession should be included in all schemes of reward. Of course, each case must be judged on its merits, and the assessment will not always be easy.

6. *State Awards for Medical Discovery.*

Honours, prizes, and medals, being bestowed by H.M. the King or by public bodies and learned societies, are acts of grace which are generally given after much consideration; and the Committee does not purpose to consider them. But the subject of *pecuniary awards* lies entirely within its province. During the last few years the British Government has disbursed an annual grant of about £60,000, under the Medical Research Committee, for subsidising *investigations in progress* authorised by the Committee and carried on by workers selected by it. This grant does not remunerate discoveries *already made*, but proceeds upon the principle of payment for benefits *already received*, deserves close attention and has been recognised in other countries.

We think that both principles are sound. But they apply to two different classes of research, and are, indeed, complementary of each other. Payment for prospective benefits is "good business" only when some return is almost certain; and for this reason subsidised researches must frequently deal with simple and straightforward questions admitting of immediate experimental reply. But, as a matter of fact, most of the greatest medical discoveries were built upon a much more speculative and uncertain basis; and were achieved by men who neither sought nor received subsidies for those investigations—as, for instance, Küchenmeister, Jenner, Sims, Simpson, Lister, Koch, Laveran, Bancroft, Manson, Bruce, Mackenzie, and a score of others who have so greatly improved medical practice. Surely the State should encourage this class of investigation also—partly because it costs the State nothing in the doing, and partly because it seems to achieve the greatest results. And there is only one way to encourage it—by paying for discoveries when made. Payment for benefits received is always not only "good business," but also a moral obligation. There are at present hundreds of medical men and others in this country who possess the knowledge, the brains, and the opportunity for private independent discovery, without subsidies, but who do not attempt it because medical research work does not

pay even when brilliantly successful. Let these men also be brought into the fold of research by offering them reward when they succeed.

We therefore suggest that in addition to assisting investigations in progress it is proper for the State to remunerate those of its subjects who have already conferred the benefits of medical discovery upon it, just as it is proper for a patient to pay his doctor. And this policy will be not only an act of justice but an act of wisdom.

Our proposals are in detail :—

(1) That Parliament should resuscitate the precedent of Jenner by paying *compensation* when due for losses incurred in achieving medical discoveries.

(2) That Parliament should provide an annual sum, say of not less than £20,000, for life pensions to be given as rewards to such of His Majesty's subjects as have made worthy medical discoveries, such pensions amounting to between £500 and £1000 a year.

Such pensions would be preferable to donations in capital, and the sums suggested would be sufficient, because men of science seek only such independence as will enable them to employ their talents in the manner they think best.

The procedure of allotment should be similar to that used for the Nobel Prizes and for the honours and medals of learned societies—that is, full particulars of the work of all applicants should be kept and considered. Parliament grants large subsidies to soldiers and sailors, has appointed a commission to consider awards to inventors, and allows patents. It should not, therefore, complain if the medical profession, which has done so much for the nation during the war, now asks for some similar consideration.

(This Committee is concerned only with medical research, but recognises that similar awards should be given to workers in other fields.)

The Joint Committee.

The following are the members of the Joint Committee :—

Representing the B.M.A.—Sir T. Clifford Allbutt, K.C.B., F.R.S., Dr. R. T. Leiper, Professor Benjamin Moore, F.R.S., E. B. Turner, Esq., F.R.C.S., Professor J. S. Haldane, F.R.S.

Representing the B.S.G.—Lieutenant-General Sir Alfred Keogh, G.C.B., Colonel Sir Ronald Ross, K.C.B., K.C.M.G., F.R.S., Professor W. Bayliss, F.R.S., Dr. D. Sommerville, Sir Richard Gregory, Lieutenant-Colonel O'Meara, C.M.G., late R.E.

THE PRODUCTION AND DISTRIBUTION OF MILK.[1]

IN April, 1917, a Committee was appointed, on the instruction of the Cabinet, by Lord Ernle, the President of the Board of Agriculture and Fisheries, with the concurrence of the Food Controller, the late Lord Rhondda, "to report on the production and distribution of milk, including the consideration of the steps which should be taken (1) to stimulate production; (2) to conserve milk-supplies during any period of excess ; (3) to provide for the special needs of children in urban centres ; (4) to effect economies in the cost of production and distribution ; (5) to organise supplies by administrative action, so as to reach all sections of the community; and (6) other kindred subjects." During the period of inquiry three interim reports have been issued dealing with questions of immediate urgency. These were published respectively in June and November, 1917, and November, 1918 (C.D. 8608, C.D. 8886, and C.D. 315).

The report before us, which is final, deals chiefly with matters affecting the milk industry and its development in the future, including both the period of post-war abnormal conditions, which we may safely and sadly predict will continue for some time, and the subsequent period when the effects of war will no longer operate. The report is signed by a strong personnel, with Viscount Astor as chairman, and the list of witnesses—representatives of the agricultural and dairy industries—interviewed by the Committee adds authority to the recommendations which have been drawn up.

Population in Relation to Producing Capacity.

One early and outstanding feature of the report is the fact that the production of milk in Great Britain in recent years has not kept pace with the increase in the human population nor with the demand of the latter for milk products. It will be agreed that an increase in the human population since 1871 of 60 per cent. against an increase in the number of cows and heifers of only 40 per cent., as compared with an increase in the weight of imported dairy products of 235 per cent., cannot be considered as satisfactory. The increased importation of condensed and dried milk is enormous, and the value of imported dairy products reached in 1914 no less a sum than £38,000,000. And yet the Committee reports that the countries exporting these products to our shores have no natural advantages of climate or soil which are not possessed to an even greater degree by large sections of the United Kingdom, which also offers to the British dairy-farmer the advantage of proximity of markets. In other words, the British dairy-farmer is found wanting. He has shown a lack of enterprise or intelligence, and has neglected the opportunities which this report brings to view—opportunities and advancement of the greatest importance to the well-being of the community. Let it be granted that no Government has done much to help him in his difficulties.

The Nutritive Value of Milk.

The Committee has previously put on record the well-considered opinion that the average consumption of milk in the United Kingdom is much lower than is desirable in the national interest. As is pointed out, milk contains all the nutritive constituents required by the body in a readily assimilable form, which makes it a valuable food for all classes of the community, and especially for children. For infants who are dependent on artificial feeding milk is obviously essential, and in the opinion of the Committee milk ought to be available in greater quantities than are at present obtainable. This serious conclusion means a milk shortage, which threatens the life and vitality of coming generations. The importance, besides, of the presence of growth-promoting substances in milk is well indicated in the report.

It is not surprising that the inquiry brought to light the unsatisfactory conditions of the milk industry in this country, while evidence is given showing that an increased consumption and production of better and cheaper milk are urgently needed. This, it is admitted, cannot be accomplished hurriedly, and only real progress can be made by such methods as will command sympathy and coöperation from both producers and consumers.

An Enlightened Milk Policy.

In the Committee's opinion the aims of an enlightened milk policy should be :—

(*a*) To bring about the utmost possible economy in production in order that: (i.) prices may be kept at as low a level as possible to the consumer, and consumption thus increased to the desired standard ; (ii.) an adequate supply may be brought within the reach of the poorest families.

(*b*) To improve the hygienic quality of milk and to ensure that the portion of the supply which requires or is subjected to pasteurisation is efficiently pasteurised under supervision.

(*c*) To increase the total supply in order to meet the extended consumption that should follow improved quality and the education of the public with regard to the nutritive properties of milk.

(*d*) To prevent the exploitation of the producer or the consumer by any trust or combination, either of a provincial, national, or international character.

In regard to pasteurisation, the Committee suggests that a definition of pasteurised milk should be set up, and that it should be sold as such and not as fresh milk. It regards pasteurised milk as by no means a substitute for clean milk production and cleanliness in handling milk.

Herd Management and Economy of Production.

There are interesting details in the report as to herd management and many other dairy-farming details, but we may note the remark that probably the greatest economy in the production of milk can be effected by increasing the yield of individual cows. It is pointed out that if the average yield per cow in the United Kingdom could be increased by one-tenth of a gallon per day the cost of milk at present prices would automatically fall about 2*d.* per gallon without affecting the profit made by the farmer. By paying stricter attention to the methods of feeding it is reckoned that an increased yield from 1½ to 2 gallons per cow could be effected, which would solve the problem of scarcity and materially bring down prices. Then comes the suggestion of official milk-recording centres being established, a scheme which, in the opinion of the Committee, has been by far the most effective agent in the improvement of dairy stock throughout the world. Sensible proposals are also made in regard to the selection of dairy bulls, the real test of which should be the power to beget offspring which will yield large quantities of rich milk.

---

[1] Final Report of the Committee on the Production and Distribution of Milk (Cmd. 483). Price 1s. 6*d*. net. Printed and published by His Majesty's Stationery Office.

Conclusion.

Such are some of the salient features of the report, a study of which shows how thoroughly the Committee has gone into the great and manifold questions involved —questions, amongst many others, of improved transport facilities, preservation, and uncontaminated supplies. Agricultural developments apart, which deserve the serious consideration of the dairy industry with a view to increased production, the hygienic or scientific demands have received anxious attention, the Committee evidently having settled upon the need of adopting a policy which should lead to the ultimate provision of both a clean and an abundant supply of milk to the community.

CONTROL OF VENEREAL DISEASES.

The Anti-Venereal Campaign.

THE campaign against venereal disease so ably inaugurated by the National Council for Combating Venereal Diseases is in danger of losing in effectiveness from an internecine struggle with the Society for Prevention of Venereal Disease, of which it was the predecessor and in large measure the progenitor.

The position of the N.C.C.V.D.—In their memorandum of Nov. 10th the National Council made these among other statements :—

> 2. It is no part of our policy to conceal the truth, and we have always acknowledged the value of cleansing and disinfecting materials, applied early and thoroughly, in diminishing the risk of disease.
>
> 3. Abstention from exposure to infection is the only certain safeguard against the ordinary risk of disease; continence is to be encouraged by every means and on every ground, both social and hygienic.
>
> 4. No person who has indulged in promiscuous intercourse can be sure that he is not infected, and every such person is, therefore, bound in duty to him- (or her-) self and to society to seek means of cleansing at the earliest moment.
>
> 5. For this purpose a thorough local application of soap-and-water is of great value, followed (if possible) by the use of such disinfectants as may be recommended by a medical practitioner.

It is evident from these clauses that the National Council believe in the efficiency of immediate self-disinfection and advocate its application. The work of the Council, freely spent in the inculcation of chastity, needs no emphasis from us.

The position of the S.P.V.D.—The Venereal Prevention Committee, or, as it has now become, the Society for the Prevention of Venereal Disease, advocates the immediate application by the individual concerned of certain disinfectants, selected by a consensus of opinion on the part of the medical members of the society. In this respect the suggestion enunciated by the N.C.C.V.D. in Clause 5 of their memorandum is complied with. With regard to the attitude of the society to the question of morality, there is no colour for the suggestion which has been made that its members are indifferent to the importance of promulgating the value of chastity. Lord Willoughby de Broke, in his speech in the House of Lords on Dec. 10th, made it clear that the importance of chastity was realised by the society over which he presides. Because the immediate objective of the society is the direct prevention of disease, and because it takes the dictates of morality as read, this does not imply indifference or antagonism. At a recent meeting, held under the auspices of the Insurance Faculty, Miss Norah March enunciated the views of the society thus :—

> "In the meantime we must face the problem of the unchaste. Are they to be allowed to continue unaware or insufficiently appreciative of the possible consequences of unchastity? or are they to be impressed with the necessity —if they are determined on anti-social behaviour—for safeguarding themselves, in so far as it is humanly possible, in the interests of others, from the possible consequences of their action? Surely it is a matter of moral responsibility to take all possible precautions, and such education as the Society for Prevention of Venereal Disease proposes to put at the disposal of the public is intended *to throw onus upon the individual*, to make him responsible, if he does not conform to the social code, for limiting the evil results of his anti-social behaviour to the narrowest degree possible."

The society does not advocate free distribution of prophylactic packets or the indiscriminate urging of people to provide themselves with them. Its members, while recognising the value of chastity, realise also that many individuals will, in spite of all deterrents, indulge in promiscuous intercourse, and they regard it as their duty to the community to ensure that such individuals are acquainted with methods of reducing their chance of acquiring and conveying infection. The society would confer a greater gain on the community by laying more emphasis, in the instructions which they issue, upon the value it attaches to the practice of continence, and upon the undoubted fact that, while properly applied medicaments will in the majority of cases ensure safety, yet there can be no absolute guarantee.

The future of these two bodies.—It would be a national calamity if the effort associated with either of these bodies were to be eliminated. Should the National Council sink into abeyance, its valuable educational and propaganda work at home and abroad would be nullified. In view of the fundamental similarity of policy in the programmes of the N.C.C.V.D. and the S.P.V.D. there is nothing to preclude members of the one body from assuming or retaining membership of the other. By such a condition of dual membership a better understanding might be reached and unnecessary friction obviated. There is no logical reason against the dual allegiance, since, as we have seen, both bodies inculcate the need of immediate self-disinfection and both are alive to the importance of the practice of chastity. A conjoint crusade would be to the national gain. The National Council has the machinery, the experience, and the staff for organising and effectively carrying out educational measures. The Prevention Society appears the better adapted for stamping out disease by sanitary methods. By a sympathetic and broad-minded coöperation in principle and a wise division of specialised labour there is an opportunity of benefiting both the generation that is and those which are to come.

A Plea for an Experimental Early Treatment Centre for London.

Whilst controversy rages with regard to the respective merits of immediate disinfection and early treatment, hundreds of individuals are daily becoming infected in London alone. Insistence is laid by the advocates of early treatment upon the necessity which exists for individuals to seek assistance within a few hours after exposure to infection. In order that this advice may be put into practice it is necessary for an early treatment centre to be available during the whole of the 24 hours of the day. As far as we are aware no such accommodation exists. We strongly urge the necessity of at once instituting such a centre, and thus rectifying a position which is as illogical as it is callous. The advantages of an all day and night centre would be multiple.

> 1. It would undoubtedly prevent the development of much disease, especially amongst those (and they will long be with us) who for various reasons do not have recourse to immediate self-disinfection.
>
> 2. It would, after trial, give a substantial idea as to the necessity, quantitative and topographical, which exists for such centres.
>
> 3. Being admittedly of an experimental nature, improvements in technique and organisation which presented themselves could readily be adopted. After the attainment of a reasonable standard of perfection other clinics could then be founded and worked on similar lines.

The organising, equipping, and staffing of an experimental pioneer centre need occupy but a short time. If instructions were given to-day such a centre could be in full working order in two to three weeks. Knowledge of the existence and the situation of the centre could be promulgated by the same methods as are already utilised for making known the ordinary V.D. clinics. The number of cases attending these clinics are increasing rapidly, and we are justified in regarding the carrying out of the above suggestion as essentially an emergency measure. We commend it to the Ministry of Health and the medical department of the London County Council.

The Appointment of Medical Officers to Treatment Centres.

It was inevitable that, during the war, venereal clinics should be placed in charge of medical men who had but little experience in the diagnosis and treatment of venereal diseases. Now that the number of specially qualified practitioners has increased, it is necessary in the interests of the community at large for clinics to be placed in charge of those who have gained sufficient experience to justify their acceptance of such posts. Unless a high standard of efficiency is insisted upon treatment will be prolonged and its cost unnecessarily increased. No electoral body should appoint a medical officer to take charge of a clinic unless he produces evidence of adequate instruction in a recognised institution or has otherwise gained equivalent experience.

The Low Venereal Record in the American Expeditionary Forces.

Colonel Ashburn[1] of the United States Army states that the incidence of venereal disease in the American Expeditionary Forces varied for the greater part of the time, during which large numbers of American troops were present in France, between 62 and 31 per 1000, the average being about 45 cases per 1000 men annually. The rate rose rapidly as troops were being sent home, but this rise was partly fictitious, and the true rate at this time could not be determined. It was a remarkable fact that the corresponding incidence in the United States was always reported as higher than in France, averaging about 60 even after the armistice. In order to set an explanation of the low incidence rate of venereal disease in France a questionnaire was sent out to obtain information on the following subjects: (1) What is the percentage of chaste men among soldiers? (2) What is the average number of unprotected venereal contacts to each case of venereal disease? (3) What proportion of men have been exposed to venereal disease without using prophylaxis? More or less complete answers were obtained from 13,648 men located in four base sections, principally at Bordeaux, St. Nazaire, Brest, and Tours. It was found that 34 per cent., or about a third, had abstained from sexual intercourse while in France. Another third of all the men had indulged in intercourse so infrequently as to make their chance of acquiring disease quite small, so that relative continence was probably next in importance to real chastity in keeping down venereal disease. From a study of the replies and from collateral evidence Ashburn came to the conclusion that in France there were about 30 unprotected contacts with women of promiscuous sexual habits for each case of resulting venereal disease, while prophylaxis reduced the incidence to about one-third of what it was without prophylaxis. The much greater relative frequency of soft chancre in France, approximately two-fifths of all venereal disease, and the lesser relative frequency of gonorrhœa suggested that prophylaxis was less effective against chancroid than against gonorrhœa or syphilis. The contact rate among men on leave was very high. 50 to 70 per cent. of the venereal disease in the army came from leave areas, and from towns en route thereto. According to statements made by 614 men with venereal disease alcohol seems to have played a smaller part as a factor predisposing to venereal disease in the American Expeditionary Force than might have been supposed. Of the 614 only 215 admitted the use of alcohol before exposure, and 85 admitted intoxication.

A Post-graduate Course of Instruction.

A post-graduate course of instruction in the diagnosis and treatment of venereal disease is being arranged by Mr. K. M. Walker at St. Bartholomew's Hospital Clinic, Golden-lane, E.C., established by the Corporation of London. The first course will be confined to male practitioners, of whom 15 can be accommodated. The suggested dates are Thursday afternoons at 5.30 P.M. The beds attached to the clinic are available for the reception and study of suitable cases in addition to work in the out-patient department. Any medical practitioner wishing to attend is invited to send his name to the Medical Secretary, National Council for Combating Venereal Diseases, 81, Avenue Chambers, Southampton-row, London, W.C. 1. If more than 15 names are received a second course will be held as soon as possible after the termination of the first.

TUBERCULOSIS.

Tuberculosis in Birmingham.

THE report on tuberculosis in Birmingham in 1918 by the chief tuberculosis officer, Dr. G. B. Dixon, brings out many points of exceptional interest. In this year, 3254 cases of tuberculosis were notified, as compared with 3543 in 1917. The mortality for 1918 was 1385, and as somewhat similar figures have been returned for earlier years, the calculation is made that the actual mortality among the cases notified is about 42 per cent. In other words, about 58 per cent. of the persons notified recover. In Birmingham there are more than 16,000 cases of the disease at any one time, the cost of which to the city is at least one million a year. There is, therefore, every justification for the expenses incurred in stamping out the disease, all the more as there are many indications that its incidence is being reduced. As judged by notifications, the report shows a definite decline of the incidence of pulmonary tuberculosis. The war has, however, increased the mortality among the persons already suffering from tuberculosis. A comparison with the notifications in five other large towns shows that, with 248 notifications per 100 deaths, Birmingham comes first, the ratio of notifications to 100 deaths being as low as 167 in Manchester, and 176 in Leeds. A table showing the incidence of, and mortality from, tuberculosis at various ages brings out the curious fact that whereas the incidence and mortality are about equal in the two sexes up to the age of 15, at every age-period over 15 the incidence and mortality are much higher in the male—often more than twice as high. Those who maintain that bad housing is the most important factor in producing tuberculosis will be surprised to find that in 1918, as in previous years, the incidence of the disease among males aged 35 to 45 was 7·69 per 1000 living at these ages, as compared with 3·33 per 1000 females of the same age. Again, the mortality rates at these ages for males was 4·46, as compared with only 1·55 per 1000 for females. Yet women at these ages spend far more of their time in the dwelling-house than do the men. The report includes an account by Mr. J. Malcolm, M.R.C.V.S., of tuberculosis with reference to the milk-supply.

Borough of Poplar Dispensary.

The report of this dispensary, which was founded as a memorial to King Edward VII., is for the years 1917–18. Many pages are devoted to tables showing the amount and nature of the work done. The scope of this work is ever widening and bringing the dispensary into some new official relationship or other. But the lack of suitable institutional accommodation for advanced cases of pulmonary tuberculosis is deplored, and the fact that such cases are still dependent on the Poor-law infirmary is recognised as a grave flaw in the antituberculosis campaign.

Sanatorium Benefit in Ayr.

In the report for 1918, the Insurance Committee for Ayr reviews the results of institutional and domiciliary treatment since July, 1912. The total number of applications made for sanatorium benefit was 1375. Of these cases, 887 received treatment, and of these again, 289, or 32·58 per cent., terminated fatally. Many of the 163 patients who could not be traced were also probably dead. The calculation is then made that about 41 per cent. of the patients treated since July, 1912, were dead. Another series of investigations into the subsequent histories of patients who had undergone treatment showed that of 200 patients who were in different states of health after treatment in 1915, as large a proportion as 29·5 per cent. were dead by the end of 1918. With regard to the 52 discharged soldiers who had completed their treatment, about 46 per cent. were already dead.

---

[1] Journal of the American Medical Association, Dec. 13th, 1919.

Sanatorium Benefit in Wigan.

In the report for 1918, the tuberculosis officer for the county borough of Wigan, Dr. G. Jessel, analyses the results of sanatorium benefit since July, 1912. Of the 568 applicants for benefit, 491 were actually suffering from pulmonary tuberculosis, and of these again 184 were alive at the end of 1918. The number of patients who could not be traced was 90. Of the 184 who were traced 84 were fit for work, 46 were fit for light work, and 54 were unfit for any work. Thus about 71 per cent. were fully or partly restored to working capacity. On the other hand, 217 were dead.

List of Sanatoriums Approved by the Ministry of Health.

The Ministry of Health, in a circular dated Nov. 29th, 1919, has drawn attention to a list that has recently been drawn up of the sanatoriums and other residential institutions approved by the Ministry under the National Insurance Act, 1911, for the treatment of persons suffering from tuberculosis and resident in England and Wales. The names of the administrative counties and county boroughs in which these institutions are situated are given, as well as the date on which the approval expires in each case. This list, price 3*d.*, can be obtained from H.M. Stationery Office. The Ministry's circular also reminds local authorities that no fee is payable in respect of the notification of cases of tuberculosis under the Public Health (Tuberculosis) Regulations, 1912, by the medical officer of a sanatorium, as defined in Article 1 (1) of the Regulations.

Milk and Tuberculosis.

The Committee on the Production and Distribution of Milk accepts the findings of the Royal Commission on Tuberculosis to the effect that :—

> "Primary abdominal tuberculosis in man, as well as tuberculosis of the cervical glands, is commonly due to ingestion of tuberculous infective material. A considerable amount of tuberculosis of childhood is to be ascribed to infection with bacilli of the bovine type transmitted to children in meals consisting largely of the milk of the cow."

The Committee is aware that subsequent work has confirmed this. At the same time it does not desire to create unnecessary alarm by exaggerating the extent of human tuberculosis due to bovine infection, for it realises :—

1. That much infantile debility leading to susceptibility to many diseases including tuberculosis is due to inadequate milk consumption.
2. That many children must be drinking some tuberculous milk without suffering evil effects.
3. That all reacting cows do not necessarily give tuberculous milk.
4. That the risk from tuberculous milk may be practically removed by efficient pasteurisation.

A MONTHLY RECORD OF ATMOSPHERIC POLLUTION.

There were no returns during the month of June from the following stations: Victoria Park and Wandsworth Common (London); Manchester; Newcastle-on-Tyne; Rochdale; St. Helens. Lead was reported present in the deposit of all the Glasgow samples, and vegetable matter in the gauge at Bellahouston Park (Glasgow).

During July there were no returns from the following stations: Manchester (two stations); Newcastle-on-Tyne; Rochdale. At Blythswood Square (Glasgow) the volume of the sample was insufficient for complete analysis. The insoluble matter in the majority of the Glasgow deposits contained lead, and in the gauge at the Botanic Gardens of that city there was vegetable matter.

"Tar" includes all matter insoluble in water but soluble in CS_2. "Carbonaceous" includes all combustible matter insoluble in water and in CS_2. "Insoluble ash" includes all earthy matter, fuel, ash, &c. One metric ton per sq. kilometre is equivalent to: (*a*) Approx. 9 lb. per acre; (*b*) 2·56 English tons per sq. mile; (*c*) 1 g. per sq. metre; (*d*) 1/1000 mm. of rainfall. Tr. = Trace.

The personnel of public health authorities concerned in the supervision of these examinations and of the analytical work involved remains the same as published in previous tables. The analyses of the rain and deposit caught in the gauge at the Meteorological Office are made in THE LANCET Laboratory.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Registrar-General's Report.

THE report of the Registrar-General for Ireland for 1918 was issued last week. In some particulars the report is encouraging. The marriage-rate—5·15 marriages for 1000 of the population—is 0·34 above that for 1917, but 0·05 under the average for the ten years 1908–17. The birth-rate—19·9 per 1000—is 0·2 per 1000 above that for 1917, but 2·5 under that for the ten years 1908–17. The death-rate—18 per 1000—is 1·4 per 1000 above that for 1917, and 1·1 above that for the ten years 1908–17. The outstanding feature of the mortality statistics is the excessive mortality due to influenza and pneumonia. Deaths from influenza numbered 10,651 as against the average for ten years of 1234, and from pneumonia 6120 as against an average of 4067. The mortality from tuberculosis showed a slight fall. The rate was 2·19 per 1000, being 0·05 under the average for the previous ten years. The infant mortality was also less—86 per 1000 as against an average of 91.

The Dublin (83) General Hospital.

The members of the units which staffed the Dublin (83) General Hospital at Boulogne in 1917 and 1918 have held recently the first of what it is hoped to make a series of annual dinners, under the chairmanship of the organiser of the hospital, Colonel William Taylor, C.B. Of the 29 officers who served in the Dublin units one, Dr. Charles M. Benson, died early in 1919 of influenza. Twenty-three of the others attended the dinner, and renewed memories of a happy comradeship in France.

The Queen's University of Belfast.

The Vice-Chancellor's report for the session 1918–19 has just been published. There were 888 students enrolled—610 men and 278 women. 549 students (418 men and 131 women) were enrolled in the Faculty of Medicine—in other words, there were 210 more medical students than the combined number of students in all the other faculties. These figures demonstrate that the Queen's University of Belfast is largely becoming a medical university. Colonel T. Sinclair, C.B. (professor of surgery) was appointed registrar of the University and Representative on the General Medical Council.

Epidemic Disease in Belfast.

Belfast is still suffering from a widespread incidence of scarlatina, measles, mumps, and chicken-pox, exceeding in numbers all previous experience. Some attribute this unfortunate state of affairs to the crowded condition of the city, where in the working-class districts houses are so scarce that often two families reside in the ordinary accommodation for single families; while others believe the outbreaks to be due to the prolonged drought in summer and early autumn.

Jan. 6th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENT.)

The War Work of the Indian Medical Service.

SINCE August, 1914, just short of 400 civil I.M.S. officers have been handed over to military authorities. During the war 71 were reverted from time to time, and since the termination of hostilities other reversions have taken place to fill essential billets on the civil side. But while the number of I.M.S. officers on the civil side before the outbreak of the war was over 500, there are now less than 200 on the civil cadre. Many of these, moreover, have been continuously at work for seven or eight years, and for the last five have been doing double work. The whole resources of the civil side of the service have been placed unreservedly at the disposal of the military authorities. The officers thus transferred from civil to military have supplied the nucleus round which the Indian Army has been able to build up an adequate corps of medical personnel. The trained war reserve thus constituted made it possible to maintain the medical services even when the Indian Army was so largely increased. Each regular I.M.S. officer has been practically a training centre for two or three temporary Indian I.M.S. officers who joined up during hostilities. The Indian Medical Service has gained one V.C., 59 M.C.'s, 46 D.S.O.'s, 8 C.B.'s, 23 C.M.G.'s, 41 C.I.E.'s, and 41 Orders of the British Empire of various grades. 533 I.M.S. officers have been mentioned in dispatches, 24 have gained foreign decorations, and 60 have been mentioned in the *Gazette of India* for services rendered in connexion with the war. The work of the I.M.S., both on the military and civil side, has been worthy of its highest traditions, and constitutes a record which any service in the Empire might well envy.

Instruction in Elementary Hygiene.

The efficient teaching of elementary hygiene in Indian schools would undoubtedly prove of great value to the community. It has been argued that a serious difficulty in the way of including hygiene in the curriculum is the apathy or inefficiency of the teaching staff. This argument may be pushed too far, just as the complete indifference of the people at large to measures for the prevention of disease has been exaggerated. A specific instance of what teachers may do to help the medical authorities is forthcoming in the notes on vaccination in the Central Provinces for 1918–19 by the Sanitary Commissioner, who remarks that it is a regrettable fact that although vaccination is a certain preventive of a deadly disease municipal committees are often so absorbed with petty affairs that they shut their eyes to the matter. In another part of the notes referring to the revaccination work done by the dispensary medical officers the Commissioner observes that "these medical officers brought to light many unvaccinated children, who were subsequently vaccinated with the help of the schoolmasters, most of whom render great help nowadays in the cause of vaccination." If the rising generation were properly instructed in health matters the municipal committees would in time be compelled to devote more attention to the prevention of disease.

Tuberculosis in Bombay.

The attention of the municipal corporation has been called by the executive health officer to the need for providing adequate hospital accommodation for tuberculous cases, including phthisis, among the poorer classes. The health officer estimates the number of attacks annually at 10,000, which is about five times the number of deaths from the disease. He points out that at any given time not less than 5000 are ill with tuberculous disease in Bombay, and proposes hospital accommodation with 200 beds for advanced cases.

Shillong Pasteur Institute.

The second annual report of the Shillong Pasteur Institute for the year ending December, 1918, has just been issued, and shows that 1068 patients underwent the complete course of treatment; of these, 90 were Europeans (including 7 Anglo-Indians) and 978 were Indians.

DEVON AND EXETER MEDICO-CHIRURGICAL SOCIETY. —A meeting was held at the Royal Devon and Exeter Hospital on Dec. 18th, 1919, the President, Dr. Ransom Pickard, in the chair. Mr. A. L. Candler read a paper on the Diagnosis and Treatment of Liver Abscess, based on cases personally met with on the Salonika and Mesopotamia fronts and during the recent operations on the North-Western Frontier of India. In the discussion which followed Dr. L. P. Black referred to cases under his care during the Gallipoli campaign of 1915. Dr. S. Steele-Perkins mentioned a case where persistent crepitations at the base of the right lung gave way to emetine injections. Dr. W. Gordon recounted three cases coming under his observation in which difficulties of diagnosis had arisen. In reply to several questions Mr. Candler urged the importance of an epigastric incision in cases where symptoms still pointed to an abscess in spite of a negative puncture.

Correspondence.

"Audi alteram partem."

THE JUSTIFIABILITY OF THERAPEUTIC LYING.

To the Editor of THE LANCET.

SIR,—In your issue of Dec. 27th, 1919, Dr. C. S. Myers, in the course of a violent denunciation of the treatment I adopted in the case of the patient with hysterical sleeping attacks (THE LANCET, Dec. 20th, 1919) uses strong language. Let me assure him that the principles of this treatment of 18 months ago differ in no way from those to which I would have consented in the case of similar illness in a member of my own family. Such a consideration, to my mind, will always be a reliable guide to any medical man who may have occasion to assess the motives which underlie his professional conduct. Further, I showed my patient and narrated the whole story of his illness to a medical gathering presided over by the President of the Royal College of Physicians of London. My considered opinion was, and is, that I did right in advising the patient to submit to the treatment, and I should like to express my appreciation of the support I received from the large body of my colleagues in circumstances which gave to their loyalty a special value.

Dr. Myers reiterates the word "needless" in referring to my procedure, yet he does not so much as outline his alternative treatment. The fear of failure of the remaining method of treatment known to the doctor (after consultation) should not weigh with him so long as there is a remote chance that it will benefit his patient, and, in my opinion, the risks to himself which the doctor may think likely to follow failure of a particular form of treatment are unworthy of any but passing consideration, provided that the requirement which I have mentioned is fulfilled. Risks have to be faced, and in this case the patient's future was at stake. He said that in the past he had been punished repeatedly for a disability over which he appeared to have no control, and it was in the hospital asylum, to which he had been sent with an erroneous diagnosis, that I found him. Deception in one of its many guises will probably continue to be used by some doctors for some cases as long as treatment of disease lasts, although it is a commonplace that the number of hysterical symptoms which appear to demand deception for their relief is every year becoming smaller. Frequently when an appeal to his reason has failed to cure a patient he has thanked me for giving him the chance of cure by an appeal to his imagination. He prefers a cure, however produced, to the alternative of discharge with his symptoms unrelieved.

When I decided to publish my paper I anticipated criticism and looked forward to it. The value of fair constructive criticism is beyond price, but I question the courtesy, to say the least, of the medical man who in the course of his criticism publicly asserts that in his opinion a fellow practitioner has adopted a procedure unworthy of his profession in the treatment of a patient.

Will you allow me to draw attention to a small mistake in my paper? On the last page "December, 1919" should read "December, *1918*."

I am, Sir, yours faithfully,

Harley-street, W., Jan. 3rd, 1920. HILDRED CARLILL.

THE DRAFT REGULATIONS FOR 1920.

To the Editor of THE LANCET.

SIR,—As Dr. H. B. Brackenbury, in his comments on my letter on this subject, says that almost every sentence which purports to be a statement of fact is either false or misleading, I must ask you for space for a reply. A conference that gives its approval to regulations which declare the decisions of the Minister to be final, that objects to an appeal to a court of law, that connives at the fact that the Minister may be both accuser and judge, that rejects clear-cut motions such as those from Stockport, Portsmouth, and Cheshire, and passes the as-you-were motion from Brighton, proclaims the Minister autocrat in the strictest sense of the term. "Speaking generally, what is resented more than anything else in the new regulations," says the *British Medical Journal*, "is the autocratic element which permeates them." Over and over again at the conferences objection was raised to the limitation of lists as curtailing the liberty of the medical man, interfering with his practice, and abrogating a first principle—free choice of doctor. Two years ago 70 areas voted for no limitations, as against 33 in favour of them. Yet the Bournemouth resolution to limit lists to 3000 was passed, although the chairman informed us that he had ruled out of order motions contrary to the decisions of the July conference. A further limitation to 2000 is a logical deduction.

I said a resolution to organise the profession to refuse service under certain contingencies was dropped as unthinkable. The minutes record that an amendment from York, "and instructs the Insurance Acts Committee to endeavour by all means to secure the refusal of all insurance practitioners to take service at any less sum" was lost. The reason given at the conference was that refusal was unthinkable; so to this day the Minister cannot make up his mind about the fee. If an insurance practitioner is responsible for all persons who have been accepted by him, for those who have left him and are perhaps out of benefit, but who have not been notified to him by the Committee as having ceased to be on his list, and for all accidents and emergencies pending their acceptance by somebody else, I say that he is at the beck and call, night and day, of anyone who can bluff him for treatment.

A practitioner shall not employ a permanent assistant to attend his insured patients without the previous consent of the Committee to the employment of such an assistant. The Committee is requested to be reasonable. Before consenting to the employment by a practitioner of more than one assistant the Committee shall obtain the approval of the Minister. In spite of these regulations the practitioner is after all responsible for all acts and omissions of any practitioner acting as his deputy or assistant. It is an old shibboleth that State money means State control. But in this case we have State control without State money.

I said that the patients whom a doctor attracts are not his but belong to the State. If the Minister confiscate Dr. Brackenbury's watch it belongs to the Minister as there is no appeal. The *British Medical Journal* has not minced words: "The Ministry of Health has stated its determination to alter the present regulations about transfers. Practitioners, for their part, are equally determined not to submit to any confiscation of the goodwill in their panel practices."

A pension scheme was literally sprung upon us a day or two before the conference. It was a red herring drawn across the trail. It was a daring move on the part of those who are out for a State service. It was resolved: "That this conference is in favour of a pension scheme for insurance practitioners to be managed by the practitioners themselves, and authorises the Insurance Acts Committee to negotiate with the Government concerning such a scheme." Resolved also: "That the question of a pension scheme for insurance practitioners be referred to local Medical and Panel Committees."

At the conference three names were added to the Association's nominees to form a deputation to the Minister. They had to inform him definitely that 13*s*. 6*d*. was the irreducible minimum that the profession would accept as a capitation fee. The interview with the Minister is published in the *British Medical Journal* of Dec. 13th. The usual arguments for better payment were advanced. That money had depreciated during the war, that the cost of living had increased, that more work meant more pay, that greater responsibility entailed greater consideration were theories new to him. His stereotyped reply reads: "That he could not see any case made out for any increased rate of remuneration."

The Ministry has taken the measure of our conference delegates. Our motions, whether passed or rejected, are entirely ignored at the Ministry. Since our conference the following most objectionable regulations were inserted in the latest draft regulations:—

> "Range of practitioners' duties. (13) A practitioner is required (*a*) to furnish in writing to the medical officer any information which the latter may require with regard to the case of any patient to whom the practitioner has issued or declined to issue a medical certificate of incapacity for work; (*b*) to meet the medical officer, when the latter so requires, for the purpose of examining, in consultation, any patient in respect of whom the practitioner has sought the advice of the medical officer; (*c*) to afford to the medical officer, or to such other person as he may appoint for the purpose, access at all reasonable times to any records kept by the practitioner under these terms of service, and to furnish the medical officer with any such records, or with any necessary information with regard to any entry therein, as he may require; and (*d*) to answer any inquiries of the medical officer with regard to any prescription issued by the practitioner, or to any statement made in any report furnished by him under these terms of service."

Is it possible to consider insurance practice reputable after this? Fortune may render us unhappy; it is only ourselves that can make us despicable.

We were once medical practitioners. We were members of a learned profession. Now by the terms of our service we are insurance practitioners. We have, in the Commissioners' own words, to safeguard the interests of the approved societies. We are agents in a business undertaking. For heaven's sake, then, let us learn business methods.

I am, Sir, yours faithfully,

Exeter, Jan. 3rd, 1920. J. PEREIRA GRAY.

THE PREVENTION OF VENEREAL DISEASE.

To the Editor of THE LANCET.

SIR,—The statements made and the statistics quoted by Lord Sandhurst in the debate raised by Lord Willoughby de Broke in the House of Lords on Dec. 10th, and published in THE LANCET of Dec. 20th, 1919, are excessively misleading. It is possible or probable that Lord Sandhurst did not grasp the purport of Lord Willoughby de Broke's inquiry. The "Portsmouth area" to which Lord Willoughby de Broke alluded is that controlled by the Assistant Director Medical Services at Portsmouth. This officer had taken great care that sanitation, including sanitation with respect to venereal disease, should be taught to the troops in his charge. Lord Willoughby de Broke desired information as to the results of this teaching, but Lord Sandhurst supplied him with something quite different.

Within the area, during the period covered by the question and answer, were stationed American, Colonial, and R.F.C. units with which the A.D.M.S. had nothing to do. Moreover, there came into the area, to take up station, or on passage through it, drafts and whole units from elsewhere (e.g., other British areas and France) among whom were many men who had become infected before coming into the area and who developed disease after arrival. Lord Sandhurst—unknowingly, no doubt—apparently added together all the disease in the Portsmouth district, no matter by whom, or when, or where contracted, and gave the sum as an answer to Lord Willoughby de Broke. In actual fact, so far from "the Portsmouth area" being 2½ times worse than the average for the United Kingdom, it is probably the model area not only for the United Kingdom, but for the whole world, and not only for British troops but for all troops. Indeed, I think it will be found that, quite apart from American, Colonial, and R.F.C. units and from whole units arriving from elsewhere, the mere drafts joining station from other British areas supplied more disease than the whole resident military population. When the smallness of these drafts as compared with the resident population is taken into account the relative superiority of the Portsmouth area may be grasped. An instance drawn from actual fact will illustrate my meaning. A certain medical officer had seven cases of venereal disease among 2000 troops in two years and four months. One day 200 men arrived from the continent, and among them the first morning's parade revealed 21 cases of venereal disease. The M.O. was proud of his results, and credited himself with a disease-rate of 1·5 per 1000 per annum. But Lord Sandhurst's statistician would have credited him with a venereal-rate of $\frac{21 \times 365}{2} =$ 3832·5 per 1000 per annum.

Lord Sandhurst stated that in two hospitals about 12 per cent. of the venereal patients stated that they had disinfected themselves quickly. I can give him additional information. In a third hospital numbers of men stated that they had disinfected themselves immediately. But closer questioning revealed that none of them had done so. The first answer was caused by a fear of blame. 495 of Surgeon Commander Boyden's sailors disinfected themselves immediately, and not one took disease. The M.O. mentioned above, who had 2000 troops in charge, taught quick disinfection, and not one of his men who employed it contracted disease during the whole two years and four months.

Suppose two surgeons, each operating on hundreds of cases, and employing the same antiseptic methods, achieved widely different results—the one getting absolute immunity and the other many cases of infection. To what should we attribute the difference? I think every medical man would say the method was good, the patients not to blame, and the unsuccessful surgeon altogether to blame. Lord Sandhurst's statistician, calculating wholly from the results of the unsuccessful surgeon, would put the blame mainly on method. However, Lord Sandhurst states: "This showed that to be effective instructions as to use of disinfectants must be given much more clearly and insistently than had been the case in the army." Here we have the gist of the matter. But instructions are usually given clearly and insistently only by those who desire their success.

I am, Sir, your faithfully,

Southsea, Jan. 4th, 1920. G. ARCHDALL REID.

THE SERUM DIAGNOSIS OF SYPHILIS.

To the Editor of THE LANCET.

SIR,—I should like to congratulate Mr. D. C. Lewis on his lucid article on the Serum Diagnosis of Syphilis in THE LANCET of Jan. 3rd. The standardisation of the corpuscle suspension used in complement-fixation tests has always appeared to me to be of prime importance, and it is a matter for wonder that the Medical Research Committee in the pamphlet on standardisation of the Wassermann reaction does not so much as attempt a standardisation of what, after all, is the basal unit from which all other reagents are calculated. It is to be hoped, therefore, that Mr. Lewis's method or some modification of it will be generally adopted. The only criticism one can offer is that it adds to the laboriousness of an already somewhat cumbersome technique. This objection cannot, of course, stand in face of the obvious advantages. It only leads one to hope for some simpler method, and I should like to ask Mr. Lewis whether he has attempted to standardise by counting the red cells by means of a Thoma-Zeiss apparatus. It appears to me that this would involve less labour and could be done at room temperature. I have done very little work on this method as yet, but it does seem that, in this way, uniform suspensions of corpuscles can be obtained irrespective of the speed of the centrifuge, &c. Furthermore, as bearing out Mr. Lewis's statements, it is surprising what differences can be got in the number of corpuscles per c.cm. in so-called "3 per cent. suspensions" made up on different occasions. Controlling the rate and time of centrifugalisation does not seem to be a practical proposition, and some such method as Mr. Lewis's is imperative if any great degree of uniformity of results is to be obtained.—I am, Sir, yours faithfully,

C. FLETCHER.

Laboratories of Pathology and Public Health,
Harley-street, W., Jan. 5th, 1920.

THE INSTABILITY OF ROUS-TURNER BLOOD SUSPENSIONS.

To the Editor of THE LANCET.

SIR,—We beg your permission to reply, as briefly as possible, to the letter in your issue of Dec. 13th, 1919, by Dr. Peyton Rous, who, we trust, will find no discourtesy in the condensation of our answer.

1. Our criticism was directed almost entirely against Professor J. S. C. Douglas and Dr. J. W. Bigger for the use they made of the suspensions, and in no way against Drs. Rous and J. R. Turner's main findings.

2. "Our conclusions are misstated," alleges Dr. Rous. But we wrote that Rous and Turner claimed no *noteworthy* change in the emulsions for three or four weeks. We did not say no change at all. By "noteworthy" we implied such changes as would render the emulsions unfit for accurate serological tests.

3. We drew the deduction from our saponin experiments that the emulsions undergo a progressive change of sensitiveness to serum hæmolysis. Dr. Rous considers this conclusion unjustifiable, and quotes the following authors in his support.

Professor H. G. Wells, in the chapter of his text-book which deals with the action of various hæmolysins, has collected a quantity of experimental evidence which shows that different hæmolysins may have different modes of action. We do not deny this; but we hold that text-book summaries should be used with much caution in criticism of detailed scientific observations. For text-books are never free from erroneous statements, nor is Professor Wells's book an exception—e.g., it is stated that saponin solutions are heat-resistant; whereas we have found that saline solutions of saponin are quickly weakened at 70° C., more slowly at lower temperatures, and even deteriorate spontaneously in a few days at room temperature.

McNiel's paper shows that jaundice may increase the resistance of red cells to hypotonic solutions, while diminishing their resistance to saponin.

Rywosch's work was with the blood of a variety of animals, some of which he showed to be highly sensitive to saponin but strongly resistant to hypotonicity, and vice versâ.

None of these data have any direct bearing upon our experiments and deduction. For we were concerned only with the actual changes taking place in a single blood emulsion, and we had no concern with different bloods nor even different emulsions of the same blood. Dr. Rous's quotations clearly do not prove that cells which increase in sensitiveness to saponin do not also change in sensitiveness to serum hæmolysin. There remains only Rous and Turner's statement that a skilled worker had found the preserved cells to be as serviceable for the Wassermann reaction as fresh cells. Dr. Rous tells us that this statement has been confirmed "in its essentials" by Reimann. Unfortunately, neither in Oxford nor from London's largest medical library have we been able to procure the journal containing his paper, and we are therefore at present not in a position to make any critical comments on this work. In any case, the Wassermann reaction is a relatively coarse and not truly quantitative test in which indeterminate variations in sensitiveness of the emulsions are constantly present. It is not capable therefore of deciding the point at issue.

4. The following facts seem to us to be quite clear and directly applicable to the matter in hand.

(*a*) Drs. Rous and Turner state that the emulsions undergo an increase in mechanical fragility during the period of preservation.

(*b*) We have demonstrated a progressive increase in sensitiveness to saponin.

(*c*) Dr. Bigger[1] has produced evidence of a similar increase towards serum hæmolysin (the actual point at issue). In the face of these findings we cannot admit that our deduction was in any way unreasonable. Upon those who deny its truth lies the burden of proof, that cells which undergo marked changes in sensitiveness to these various agencies none the less remain stable to serum hæmolysin in contradiction to Dr. Bigger's own subsequent findings. We adopted the best method we could devise for our experiments, in which the use of an absolutely stable substance—e.g., dry saponin—was essential. It is not at present possible to carry out a similar research with serum hæmolysin on account of its instability. If it had been possible we should have done it.

5. We did not use gelatin because its employment would have rendered our results incomparable with those of Douglas and Bigger, who did not make use of it.

6. Dr. Rous applies the phrase "an unusual lapse in accuracy for figures" to an observation of a purely qualitative nature which we chanced to make after our quantitative experiments had been concluded. The change in the red cells had by then reached such a pitch as to reveal itself at once even to casual inspection.

In conclusion, we trust that, even if we have failed to convince Dr. Rous himself that our saponin curves have (as we believe) a direct and fundamental bearing on the question of the stability of his emulsions, they may nevertheless prove of interest and assistance to those who are working on the lines of serological standardisation.

We are, Sir, yours faithfully,

G. DREYER.

SUBCUTANEOUS EMPHYSEMA IN PARTURITION.

To the Editor of THE LANCET.

SIR,—Four nights ago I was called to a primipara. 20 years of age, who looked a healthy, well-developed woman, but had a small pelvis and a big child with the cord round its neck. Labour much prolonged, head three hours down on perineum, and pains decreasing in strength and frequency. Patient was lying on her left side; face, pushed down into the bed, was seen on raising to be much swollen on the right side, eye closed, bridge of nose broadened, swelling extending down side of face and neck. Patient complained of sore-throat (about thyroid) and difficulty in breathing. Was delivered with forceps. The following day her face was uniformly puffed up owing to change of posture; neck distended, and swelling extending down over thorax, giving everywhere the crackling sound and sensation of dry paper. There is now slight cough, but the swelling and sore-throat are subsiding. Examination by the stethoscope is unsatisfactory because of the subcutaneous crackling.

I send this as neither I nor two experienced practitioners of whom I inquired had met with this complication, nor do I find any reference to it in my midwifery text-books (save Galabin's)—Playfair, Jellett, and Eden; but Marcus Beck mentions it in Quain's Dictionary of Medicine upon the authority of Dr. Walshe, and I think it a matter of sufficient importance to the student to warrant its being dwelt upon by his lecturer in obstetrics. Besides, it may be of more frequent occurrence than I am aware.

I am, Sir, yours faithfully,

Kettering, Jan. 2nd, 1920. J. GOOD.

THE RIGHT USE OF THE COIN-CATCHER.

To the Editor of THE LANCET.

SIR,—In view of recent articles in THE LANCET advocating the use of the œsophagoscope and deprecating the use of the coin-catcher, I would like to point out that the coin-catcher used in conjunction and with the help of the X rays is not only a simple but also a harmless and efficacious instrument. During the ten months in 1918 when I was house surgeon to the Ear Nose, and Throat Department of the London Hospita I on seven occasions removed coins or circular pieces o tin from the throats of small children who had swallowed them. These foreign bodies were always lodged at the same spot—i.e., at the level of the suprasternal notch The children were generally aged from 3 years to 6 years, and the coins had been swallowed, as far a one could ascertain from their mothers, from one day to seven days prior to admission to hospital. Unde a light A.C.E. anæsthesia in the X ray room the whole procedure of introducing the coin-catcher and extracting the offending foreign body was easily and rapidly carried out. In no instance did the operation take more than three minutes, and always within 15 minutes from the time of leaving the children were back again in bed in the ward. They were kept in one night for observation and discharged the following day with no untoward symptoms supervening. To my mind this is an ideal way of dealing with these emergencies. The whole field of operation from start to finish is under visual control, thanks to the aid of the screen; if the coin-catcher is "hung up" on trying to extract the coin any temporary hitch is easily overcome by introducing it further down the œsophagus and then gently withdrawing it, and as long as care and gentleness are used no danger should be feared. On the other hand, the use of the œsophagoscope with a small child necessitates a deeper anæsthesia, a possibility of injuring the delicate structures at the back of the throat and sometimes sets up a fatal edema of the glottis or a broncho-pneumonia. I saw two cases in which children died from broncho-pneumonia in 48 hours after the use of the osophagoscope for removal of coins, though both children were perfectly well (save for the presence of the swallowed coin) on admission.—I am, Sir, yours faithfully,

CHARLES H. CARROLL.

Lancaster-road, N.W., Dec. 31st, 1919.

THE ELSIE INGLIS MEMORIAL.

To the Editor of THE LANCET.

SIR,—In the annotation in your issue of Jan. 3rd one memorial seems to have escaped mention. I refer to the Elsie Inglis Memorial Chair in the Faculty of Medicine at the University of Belgrade. It owes its inception to the London Committee of the Scottish Women's Hospitals, and was inaugurated by a meeting at the Mansion House in June, 1918.

Thanks to the geographical position of our own land the material damage it sustained during the war was trifling, and the difficulties experienced in our medical schools and colleges are due to increased attendance, not to diminished accommodation. In Belgrade there has to be a material reconstruction of shell-shattered lecture-rooms and laboratories before any instruction can be given.

This association of Dr. Elsie Inglis's name with medical education, that she had so much at heart, and reconstruction of that country, in whose service she spent herself so unsparingly, even to the last moments of her life, seems a particularly happy one; it should commend itself to members of the medical profession in Britain, whose admiration for the courage and sympathy with the sufferings of our gallant ally have been already manifested in so many ways.

A substantial beginning has been made, but funds are still needed to complete the scheme, and may be sent to Lady Selborne, honorary secretary, Elsie Inglis London Memorial Fund, 16, Carlton House Terrace.

I am, Sir, yours faithfully,

LINA M. POTTER,
late Medical Officer to Russian Unit,
Scottish Women's Hospital.

Kensington, W., Jan. 6th, 1920.

MYALGIC PAINS AND MANIPULATION.

To the Editor of THE LANCET.

SIR,—I have read the letter of "Non quis, sed quid" in your issue of Dec. 20th, 1919, with considerable interest. Cases such as he details are not uncommon, nor is the eventual result, to wit, cure at the hands of an irregular practitioner or "bone-setter" after failure on the part of the regularly qualified very uncommon either. Such cases are too numerous and too often vouched for either actually by medical men, or, if not, by individuals whose powers of scientific observation and criticism are beyond cavil, to be merely disregarded. That these things should be so is not very creditable to our profession. There can be no doubt that there is "something in" manipulative surgery the knowledge of which is not merely still undiffused through the profession, but of which even orthopædic surgeons have by no means a full knowledge.

The commonest type of case to be benefited by manipulative surgery is found among internal derangements of the knee-joint. There can be no doubt that many patients have gained stability and perfect restoration of function in the knee-joint by the agency of manipulative procedures, without recourse to any cutting operation. Occasionally such manipulations no doubt fail, but in that case no harm has been done as nothing in the manipulations prejudices the success of the arthrotomy which is still available. On the other hand, should an unsuccessful arthrotomy be performed, and this is an eventuality which is by no means unknown, the chances of a successful manipulation being performed subsequently are greatly lessened. While internal derangements of the knee-joint have constituted the most fruitful field in the past for the triumphs of manipulative surgery, there is no doubt also a class of case, to which that of "Non quis, sed quid" belongs, consisting of some obscure derangement of the tendons or articulations in the lumbar and sacro-iliac regions, which also provides a field for skilled manipulation.

I suggest that it is consonant with the dignity of the Royal College of Surgeons of England to appoint a small commission to inquire into manipulative surgery. The really expert practitioners of this art are not very numerous, and I cannot think that they would object to giving evidence and demonstrations before such a commission. It is up to the medical profession to give them the opportunity. It is no reproach to us that persons outside the profession should have discovered useful therapeutic methods, but it would be deplorable that we, because we are affected by prejudice, should fail to do our best to make such methods available to the whole of suffering humanity.

I am, Sir, yours faithfully,

Dec. 26th, 1919. HALDIN DAVIS, F.R.C.S. Eng.

"MIND AND ITS DISORDERS."

To the Editor of THE LANCET.

SIR,—May I put some points to the reviewer of Dr. W. H. B. Stoddart's book, "Mind and its Disorders," in THE LANCET of Dec. 20th? The "cortical paralysis" from "intraneuronic intoxication" mentioned by Dr. Stoddart is said to "go strangely" with the causes of maniac-depressive insanity, which the author of the book describes as "parental fixations and repressed homosexuality." At first sight this might appear so. But, of course, there are two possibilities that come at once to the mind, upon which I should like to hear opinions. The adoption of one or other of these possibilities as a working hypothesis will depend upon whether we try to subordinate classical views to Freudian ones, or whether we attempt to bring in psycho-analysis as a vassal to the older psychiatry. Suppose we consider the intraneuronic intoxication as the primary cause of the disease, then we know that as a result many psychic abnormalities make their appearance in the higher realms of thought and reason. The form these abnormalities take is the point of interest to the psychologist, and it may be assumed that whatever particular attitude of mind or character trait it was hardest for the individual to attain under the influence of his educational surroundings, that will be the first point of his psychology to give way under the stress of disease and cease being rationalised. Now, what are repressed homosexuality and parental fixations if not weak points in the individual's adapted mentality? In this case psycho-analysis would not be showing us the primary cause of the disease, but only the factors that determine the form of the symptomatic disorders.

If, on the other hand, we assume these repressions and fixations to be the fundamental cause of maniac-depressive insanity, we must inquire into the significance of the intraneuronic intoxication. Does or does not an organ which, as a result of functional disorder, exhibits excessive activity in certain directions and diminished action in others, so destroy its internal economy as to have its vitality and resisting powers lowered to the extent of offering a likelier footing for any possible toxæmia? If so, it might well be that the abnormal functionings consequent upon repressions and fixations lay the higher cerebral centres open to the toxæmic changes that so frequently occur in the case of other organs as a result of lowered vitality and resistance.

At any rate, could it not be possible to reconcile the two points of view, rather than shutting oneself up in such a little world of one's own as debars one from accepting, let alone considering, views that are not in complete accordance with previously adopted hypotheses. I quite agree with the reviewer that it is to be regretted that Dr. Stoddart exemplifies so his views on symbolisms, especially as the book is addressed to students and general practitioners—that is, to a class of people that are probably totally unacquainted with the first and fundamental principles of psycho-analysis, and, indeed, may perhaps never have read such excellent books as have been published on sex symbolisms in religion, quite apart from analytical psychology.

I can see Dr. Stoddart smile, however, when he finds himself described as the possessor of an "unfortunate penchant for certain unpleasant phases of thought." So well does he know that a biased and instinctive dislike to a particular phase of thought is frequently but a reaction formation indicative of a personal difficulty in a similar phase of thought with subsequent repression on the part of the critic, that I am afraid that he will find additional support for the Freudian psychology in such undue criticisms.

I am, Sir, yours faithfully,

J. ERNEST NICOLE.

Kensington and Fulham General Hospital, Dec. 31st, 1919.

DIRECT INFECTION IN TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—I have been very much interested in Dr. E. Ward's interesting articles in THE LANCET on the above subject and the kindred one relating to conjugal tuberculosis. With almost all he says I am in complete accord, and I think we owe him a great debt for bringing this matter prominently before the profession at a time when such erroneous views are being ventilated with such confidence. I am, however, against regarding all cases of tuberculosis as infectious, and in his last article he has shown how foolishly the infectivity of some forms of tuberculosis can be exploited even by members of the medical profession. The question of infection is, of course, relative, and becomes almost negligible when reasonable precautions are taken, even in cases where there is abundant infective sputum; but if these precautions are omitted, as they will sure to be if the present erroneous views are further promulgated, infection is bound to follow. I would, however, remark that it is not necessarily from advanced cases that infection takes place, but often from unsuspected carriers. I remember some years ago admitting a patient whose sister had died of tubercular meningitis shortly before, and the family seemed to think that the one that had died had infected my patient. I discovered that until she was seized with head symptoms she had been in good health, but had been sleeping with my patient, who for some months had been attending the doctor for hoarseness; this was found to be due to tubercular laryngitis on admission, and events had happened as could have been foretold, the healthy girl being unprotected died of meningitis, a comparatively rare event in the course of chronic disease. This emphasises my contention that to eradicate tuberculosis the disease must be diagnosed much sooner and the cases treated in sanatoriums before they are hopeless.

I have during the last three months had four cases of well-marked tuberculosis occurring in married people. I have no doubt that infection may walk hand-in-hand with infection in many of these cases, and the seriousness of the result will depend upon the magnitude of the dose, the virulence of the bacilli, and the state of resistance of the recipient. The result being, as Dr. Ward points out, much worse in the case of a healthy previously uninfected partner.

I am, Sir, yours faithfully,

New Cumnock, Jan. 4th, 1920. EDWARD E. PREST.

Obituary.

SIR THOMAS RICHARD FRASER, M.D., F.R.C.P., LL.D. EDIN., LL.D. ABERD. AND GLASG., HON. SC.D. CAMB., HON. M.D. DUBL.,

EMERITUS PROFESSOR OF MATERIA MEDICA AND CLINICAL MEDICINE IN THE UNIVERSITY OF EDINBURGH, AND PHYSICIAN-IN-ORDINARY TO THE KING IN SCOTLAND.

WE much regret to announce the death of Sir Thomas Fraser, the veteran Professor of Materia Medica and Clinical Medicine at Edinburgh, who died on Jan. 4th at his residence, Drumsheugh Gardens, in the 79th year of his age.

Thomas Fraser was a Roxburghshire man, but his father had business relations with India, and the son was born in Calcutta in 1841. Educated in Edinburgh, he graduated in medicine at the age of 21 and immediately manifested the direction which his scientific abilities would take by obtaining the gold medal for his graduation thesis "On the Characters, Actions, and Therapeutic Uses of the Ordeal Bean" (Calabar bean, *Physostigma venenosum*). Further studies along this line, published in the *Natural History Magazine* of Edinburgh, the now defunct *Medical and Chirurgical Review*, and the Proceedings of the Royal Society of Edinburgh, were a prelude to his appointment first as assistant to Sir Robert Christison, the famous Professor of Materia Medica, and later, but at the early age of 28, as lecturer in his chosen subjects in the extra-mural school. This post he held for four years, and then, after a brief period of sanitary work in England, he was summoned back to Edinburgh in 1877 as Professor of Materia Medica in succession to Christison. From this time forward he became one of the leading pharmacologists in the country, and, indeed, in the world, and his work in association with Christison, Crum Brown, Lauder Brunton, William Roberts, and later Cushny and Elliot, has done much to secure the transformation of the drug treatment of disease from empiricism to scientific routine.

To these men, and others like Magendie and Bichat, medicine owes an unpayable debt, and in an address delivered before the Section of Pharmacology and Therapeutics at the meeting of the British Association held in Cardiff in 1885 Fraser gave a remarkable exposition of the aims of the coming pharmacology. The change in direction of pharmacological studies was indicated by his statement that he regarded pharmacology as one of the means by which the great aim of medicine, the healing of disease, could be reached, adding that as the use of drugs was one of the essential means for healing, so it therefore became of importance to arrive at a clear conception of the methods by which the investigation of pharmacological problems could be effected. This was the note of all his future work. It meant the substitution for the old-fashioned methods, whereby the action of remedies was studied through their administration in disease, of a newer science in which, the essential nature of the pathological process having been defined, accurate biological and chemical knowledge was employed to produce the substance which ought to deal with the perverted process. This application of pharmacological knowledge to the cure of disease, a problem entirely separated from that of determining the action of remedies, was illustrated by his earliest work in connexion with physostigmine, its relations to atropine, and their uses in ophthalmic procedure; his next big research into the properties of strophanthus had a similar scope. For an important publication now followed, in which he demonstrated the diuretic powers of this new drug, showing how these had been discovered and could be utilised as a cardiac remedy. An investigation of "kombé," the arrow poison of certain African tribes, revealed the plant to yield an active principle, strophanthin, and Fraser proved by experiments that this crystalline substance was in physiological action allied to digitalin and other members of the digitalis group. This discovery he set out in a paper, published in the *British Medical Journal*, which literally bristled with records of past work and notes on recent experiments, and put out all that was then known of the actions and uses of digitalis and of its substitutes, with special reference to strophanthus. The paper was recognised on all sides to be an example of the best kind of practical investigation in therapeutics, and it has formed a pattern for similar researches in many instances.

During the next decade similar practical work followed from Fraser's researches, papers on the use of nitrites in the dyspnœa of asthma and bronchitis, on the relative value of opium, morphine, and codeine in diabetes, on bichromate of potassium as a remedy in gastric affections, and on bone marrow in the treatment of pernicious anæmia being published in the *British Medical Journal*, THE LANCET, and the Transactions of the Medico-Chirurgical Society of Edinburgh. But practical progress along these lines was hampered in rather a curious manner by actual developments in chemical knowledge. This Fraser pointed out in an address delivered at the medical graduation ceremonial at Edinburgh in 1894, and published in THE LANCET. He then said that in his department of therapeutics shallow pretentions had for centuries been rife and were now being more boldly advanced than ever, with the knowledge that suffering humanity, being naturally anxious for relief, was prone to credit dogmatic assertions, especially if accompanied with a misuse of scientific phraseology. His words were a distinct warning to all that the recent advances in organic chemistry, which had led to the discovery of an unlimited number of complex substances with possible physiological actions, had brought with them temptations to charlatanism. He considered that medical men, as well as commercial chemists, were advocating the use for all sorts and conditions of disease of remedies to which no proper trial could be given, and pointed out that the determination of the physiological action of any substance, organic or inorganic, might require at least six months' study by a skilled investigator. The warning was timely and came from the right lips.

One particular direction of Fraser's work requires further mention—namely, his investigations into snake-poisoning. His researches into the action of snake-poisoning, especially the poison of the cobra, were largely made in association with Lauder Brunton and in continuation of the labours of the late Sir Joseph Fayrer, while later and in association with Major R. H. Elliot he gave the medical profession such exact knowledge as it possesses of the effect upon the cardiac action of cobra venom. Fraser and Elliot discovered that different venoms differ greatly as regards their degree of toxicity, and that the minimal lethal dose of any given venom varies somewhat for different animals, weight for weight. The animals employed were rats, rabbits, and cats, and it was found that the venom of the sea-snake produced totally different experimental results from those produced by cobra poisoning. The actions of venoms upon the circulation and the heart, previously noted by Brunton and Fayrer, were next completely studied by Fraser in collaboration with Elliot, and the result of this work was to indicate the complexity of venom substances and the variety of symptoms produced according to the amount of venom injected and the site of the injection. It was obvious, therefore, that any attempt to remove and destroy the venom deposited locally might have to be founded upon the endeavour to neutralise the poison absorbed into the general circulation, inasmuch as the attempt to deal with the injury at its site, by ligature or cautery, would be bound to fail unless put in action with an impossible promptitude. A serum treatment for snake-poisoning was thus clearly indicated, and here Calmette and Fraser were the pioneers. In 1894 Calmette published an account of extended researches into the production of immunity against snake venom among animals subjected to experimental injection. In 1895 Fraser published his account of the antidotal properties of the blood serum of immunised animals and of venomous serpents, and in the following year a paper in the *British Medical Journal* from his pen carried the subject on further, when he pointed out the limitations of the antidotal powers of antitoxin as illustrated in the antagonism between antivenene and snake venom.

In 1898 the prevalence of plague in India led to the sending out of a Scientific Commission to inquire into the cause of the epidemic, the conditions of the spread, and the methods of prevention that might be taken. Fraser was selected to act as chairman of the Commission and proceeded for a year to India in this capacity. The work of the Commission has been recognised as adding largely to our knowledge of the propagation and prevention of plague. His appointment was a public recognition of his position as clinician as well as pharmacologist, for all his work was done with appreciation of the intimate relations that must exist between therapeutics, where he was a discoverer, and clinical medicine, where in his capacity of physician to the Royal Infirmary he was an assiduous officer and successful teacher. He was, moreover, actively interested in the cause of medical education. Dean of the Faculty of Medicine of the University for a long period, he was examiner in materia medica and public health at the University of London, and in materia medica at his own University, which he also represented for some years on the General Medical Council.

The respect in which he was held is indicated by the academic honours which he received. He was a Fellow of the Royal Society, five great British universities presented him with honorary degrees, and he was also a Fellow of the Academy of Medicine of Turin and of the Philadelphia College of Physicians. He succeeded Sir William Gairdner as honorary physician to the King in Scotland, and duly received the honour of knighthood. He carried on his work as professor at the University, in spite of failing health, until the summer of 1918, when he was succeeded in the chair of Materia Medica by Professor A. R. Cushny. On his retirement the University of Edinburgh bestowed upon him the honorary degree of LL.D., and at the same time he was presented with his portrait. Alike as discoverer, teacher, and organiser, Fraser has left an abiding mark, not only upon his famous University, but upon the medical history of the country.

Sir Thomas Fraser married Susanna, daughter of the Rev. R. Duncan, by whom he had a large family. Of this the war took heavy toll, for one of his sons was killed in France and one perished in the foundering of a submarine, while a husband of one of his daughters was also killed and another son wounded. One of his surviving sons, a well-known physician in New York, accompanied the American army to France and is at present with the army on the Rhine.

GEORGE CARTER LOWE, F.R.C.V.S., M.R.C.S. ENG.

IN THE LANCET of Dec. 27th, 1919, appeared an obituary notice of Dr. Arthur Rieussett Litteljohn, who, after upbringing as a veterinary surgeon, turned to human medicine and became a valued official in the medical department of the Local Government Board. Dr. George Carter Lowe, who died on Dec. 9th, also belonged to that small band of clinicians qualified to treat both man and beast. He was born in Bermondsey in 1869, the son of a well-known veterinary surgeon with an extensive practice in Bermondsey and Southwark. After an education at the St. Olave's Grammar School he entered as veterinary student at the Royal College in 1887, qualifying M.R.C.V.S. in 1892, and after his father's death continued his practice at Oxley-street, Bermondsey. In 1906 he took his F.R.C.V.S. with a thesis on "Periarticular Ringbone in the Horse." Just previous to this he entered Guy's Hospital as a medical student, and obtained the qualification of the Conjoint Board in 1911. Dr. George Lowe then joined the partnership of Drs. Salter, Richmond, Stratton, and Goldie, and practised in Bermondsey until his death. He was doing full work up to Dec. 6th, on the evening of which he complained of a sore throat. The next day he was found to be suffering from suppurative tonsillitis with septic faucitis, which developed into general septicæmia, death occurring quite suddenly on the evening of Dec. 9th. His remains were cremated at Golders Green on Dec. 12th.

Dr. Lowe identified himself with the social life of the community to whose physical needs he ministered. He was president of the Bermondsey Adult School and treasurer of the Independent Labour Party. His good works were done by stealth, and his best memorial is a fragrant memory in a district where life is drab.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Temp. Surg.-Lieuts. L. W. Gemmell and D. A. P. Clarke are transferred to the permanent list of Surgeon-Lieutenants.

ARMY MEDICAL SERVICE.

Col. G. Dansey-Browning is placed on the half-pay list.

Temp. Col. E. F. Buzzard (Captain, R.A.M.C. T.F.) relinquishes his temporary commission on re-posting.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Col. C. J. O'Gorman relinquishes the temporary rank of Colonel.

The undermentioned relinquish the acting rank of Lieutenant-Colonel: Majors C. W. Bowle, E. D. Caddell, E. L. Moss, G. H. Stevenson; Temp. Capt. L. D. Shaw.

Temp. Capt. E. Biddle relinquishes the acting rank of Major.

The undermentioned Captains are seconded for service with the Egyptian Army: (Bt. Major) W. E. Marshall, J. Biggam, K. P. Mackenzie.

Major W. M. Power, from the half-pay list, retires on retired pay on account of ill-health.

Capt. G. S. Parkinson to be temporary Major whilst specially employed.

H. E. L. Canney, late temporary Major, to be temporary Major.

Late temporary Captains to be temporary Captains: G. Fleming, J. N. G. W. McMorris, A. Vella.

Temp. Capt. J. Higgins to be Captain.

The undermentioned Lieutenants (temporary Captains) to be Captains: W. E. Hodgins, T. S. Law.

Temp. Lieut. J. A. P. Cullen to be temporary Captain.

Lieut. E. H. W. Elkington, from Can. A.M.C., to be Lieutenant and to be temporary Captain.

W. H. Steavenson to be temporary Lieutenant.

Officers relinquishing their commissions: Temp. Hon. Lieut.-Col. M. Gamble (and retains his honorary rank). Temp. Capts. A. Anderson, (acting Major) F. G. W. Deane (granted the rank of Lieutenant-Colonel). Temporary Captains granted the rank of Major: A. S. K. Anderson, J. B. Haycraft, F. De S. McMenamin, W. Martin, E. McCulloch, E. G. Dingley, G. R. B. Purce, G. W. R. Rudkin, M. Bates, J. S. Doyle, D. B. Pascall. Temporary Captains retaining the rank of Captain: A. Renshaw, W. E. Hopkins, F. J. Strachan, E. Grey, A. J. Will, R. Thomson, N. S. Sherrard, J. D. Wright, R. H. Thomson, R. Ward, H. A. Ash, H. L. Flint, J. C. McWalter, R. S. Harvey, W. J. Poole, C. E. Sharp, O. R. Allison, J. C. Robb, H. G. Oliver, D. Malloch, J. P. Dee, D. L. Spence, W. Howat, A. R. Moore, A. E. Foerster, J. H. D. Phelps, D. Denlop, J. Menzies, S. E. Y. Elliott, H. Mortimer, R. A. Fuller, G. Habgood, N. H. Smith, V. M. Coates, F. Newey, H. J. Burke, C. G. Harmer, L. Hutchinson, A. Gregory, J. F. Allan, P. S. Marshall, V. St. L. Pinnock, W. T. Currie, J. H. Murray, R. W. Murphy, E. T. Glenny, J. A. MacArthur, T. Forsyth, J. Paxton, B. P. Parmiter, L. M. Mayers, A. L. E. F. Coleman, E. Morison, N. Reader, B. J. Cusack, S. Murray, J. Dunlop, L. W. Bain, W. J. Macdonald, H. Richmond, A. E. Schokman, R. McLean, J. A. P. Cullen, S. P. Rowlands, I. C. MacKenzie, J. Porter, J. I. Enright, J. Avery, S. J. Darke, T. W. Bayne, H. P. Fairlie, J. D. MacEwen, J. C. Knox, D. S. Campbell, R. M. McMinn, R. Brown, W. L. Cassells, S. P. Stoker, S. A. Furlong, P. D. Magowan. Temp. Lieut. P. J. F. Lynch (and retains the rank of Lieutenant).

TERRITORIAL FORCE.

Lieut.-Col. W. B. Mackay relinquishes his commission on account of ill-health contracted on active service, and retains the rank of Lieutenant-Colonel.

Major (acting Lieut.-Col.) W. A. Thompson, Capt. (acting Lieut.-Col.) F. G. Dobson, Capts. (acting Majors) L. N. Reece, D. C. Bremner, J. Everidge, F. W. K. Tough, and A. P. Thomson relinquish their acting rank on ceasing to be specially employed.

Capt. F. Ellis relinquishes his commission on account of ill-health caused by wounds, and is granted the rank of Major.

1st London Sanitary Company: Lieut. J. T. A. Walker to be Captain.

1st Northern General Hospital: Capt. N. Hodgson is restored to the establishment.

SPECIAL RESERVE OF OFFICERS.

Capt. J. B. Hanna relinquishes the acting rank of Major.

The undermentioned Lieutenants to be Captains: W. E. P. Briggs, G. Winter, G. S. Lewis, W. Oats.

ROYAL AIR FORCE.

Medical Branch.—The undermentioned are transferred to the unemployed list: Capts. W. L. Scott, R. W. Meller, J. E. Lascelles, L. A. Walker, H. Y. Riddell, C. H. Browne, and (acting Major) L. C. McL. Wedderburn.

Dental Branch.—Capt. N. H. Medhurst is transferred to unemployed list.

INDIA AND THE INDIAN MEDICAL SERVICE.

Major-Gen. G. G. Giffard, Surgeon-General to the Government of Madras, has been appointed Honorary Surgeon to the King-Emperor. Lieut.-Col. A. W. T. Buist has made over charge of the duties of Superintendent of the District Jail at Rawalpindi to Raj Sahib Lalla Gopal Das, officiating Civil Surgeon, Rawalpindi. Lieut.-Col. J. Stephenson, Principal, Government College, Lahore, has been granted one year's leave preparatory to retirement. Major W. D. Overbeck Wright is permanently posted to the United Provinces. Lieut.-Col. J. C. H. Leicester is officiating as Professor of Midwifery, Medical College, Calcutta. Dr. Baij Nath Vyas Rai Bahadur, Civil Surgeon, on special duty, is to hold civil medical charge of the Morabad District, in addition to his own duties, vice Major H. P. Cook, I.M.S., Civil Surgeon, who has been granted leave. The local Government has nominated Lieut.-Col. W. H. E. Woodwright officiating Inspector-General of Civil Hospitals, United Provinces, to be President of the United Provinces Medical Council, vice Col. C. Mactaggart, resigned. The Viceroy has selected Col. J. K. Close, officiating Surgeon-General with the Government of Bengal, for the appointment of Inspector-General of Civil Hospitals, United Provinces, in succession to Col. C. Mactaggart, who has proceeded on leave preparatory to retirement. Col. Close has spent many years of his service in the United Provinces, and his appointment will be cordially approved by all acquainted with his professional zeal.

URBAN VITAL STATISTICS.

(Week ended Jan. 3rd, 1920.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at 16,500,000 persons, the annual rate of mortality, which had been 13·9, 14·6, and 12·0 in the three preceding weeks, rose to 16·2 per 1000. In London, with a population slightly exceeding 4,000,000 persons, the annual death-rate was 17·0, or 6·4 per 1000 above that recorded in the previous week, while among the remaining towns the rates ranged from 7·0 in Eastbourne, 8·8 in Wimbledon, and 9·1 in Aberdare, to 22·6 in Hastings, 22·7 in West Hartlepool, and 27·2 in Bury The principal epidemic diseases caused 358 deaths, which corresponded to an annual rate of 1·1 per 1000, and comprised 111 from measles, 93 from diphtheria, 72 from whooping cough, 55 from infantile diarrhœa, 21 from scarlet fever, and from enteric fever. Measles caused a death-rate of 1·4 in Liverpool, 1·5 in Preston, 1·7 in Plymouth and in Darlington and 2·3 in Grimsby and in Bootle; whooping-cough o 1·4 in Norwich, 1·6 in Grimsby, and 2·0 in Aberdare; and diphtheria of 1·1 in Nottingham and in Swansea, 1·2 in Tottenham and in East Ham, and 1·3 in York. The 52 deaths from influenza were 9 in excess of the numbe in the previous week, and included 19 in London and in Salford. There were 2926 cases of scarlet fever and 1873 of diphtheria under treatment in the Metropolita Asylums Hospitals and the London Fever Hospital, agains 2873 and 1862 respectively at the end of the previous week The causes of 47 deaths in the 96 towns were uncertified and included 7 in Birmingham, 6 in London, 4 in Liverpool and 3 in Gateshead.

Scotch Towns.—In the 16 largest Scotch towns, with an aggre gate population estimated at nearly 2,500,000 persons, th annual rate of mortality, which had been 13·5, 13·2, and 14· in the three preceding weeks, rose to 15·9 per 1000. Th 328 deaths in Glasgow corresponded to an annual rate o 15·3 per 1000, and included 8 from diphtheria, 7 fro infantile diarrhœa, 5 from whooping-cough, 2 from measles and 1 from scarlet fever. The 97 deaths in Edinburgh wer equal to a rate of 15·0 per 1000, and included 3 fro diphtheria and 2 from scarlet fever.

Irish Towns.—The 155 deaths in Dublin corresponded t an annual rate of 20·0, or 8·2 per 1000 above that recorded i the previous week, and included 4 from infantile diarrhœ 2 from whooping-cough, and 1 each from enteric feve measles, and diphtheria. The 197 deaths in Belfast wer equal to a rate of 25·6 per 1000, and included 26 fro measles, 8 from scarlet fever, 4 from infantile diarrhœ 3 from enteric fever, and 1 each from whooping-cough an diphtheria.

Medical News.

University of Cambridge: Diploma in Radiology and Electrology.—Courses of lectures and practical work in Part I. (*a* and *b*) will be given at the Cavendish Laboratory, Cambridge, by Mr. J. A. Crowther, beginning Jan. 20th. Courses of lectures in Part II. (*b*) will be given in the Medical Schools, Cambridge, beginning Jan. 19th, by Dr. E. P. Cumberbatch (St. Bartholomew's Hospital), Dr. C. E. Iredell (Guy's Hospital), Dr. F. Shillington Scales (Cambridge), Dr. W. J. Turrell (Oxford), and Dr. R. S. Woods (London Hospital), as far as at present arranged. Application for attendance at these courses should be made to Dr. F. Shillington Scales, Medical Schools, Cambridge. The following hospitals are recognised by the University of Cambridge for clinical instruction in the Radiological and Electrical Department: Addenbrooke's, Cambridge; Charing Cross; Guy's; King's College; London; Middlesex; St. Bartholomew's; St. George's; St. Mary's; St. Thomas's; University College; Westminster; Royal Free; Cancer Hospital (Brompton); Hospital for Consumption (Brompton). The date of the next examination, to be held at Cambridge, has been provisionally fixed for July, 1920. Similar courses in Parts I. and II., recognised by the University of Cambridge, will be given in London, where application should be made to Dr. Robert Knox, 38, Harley-street, W.

University of London.—At a meeting of the Senate on Dec. 17th last, Dr. Sydney Russell Wells was elected Vice-Chancellor for the remainder of the year 1919–20, in the place of Sir Cooper Perry, who has been appointed Principal. Professor William Bulloch, F.R.S., was appointed as from Jan. 1st the first occupant of the newly established Goldsmiths' Company's chair of Bacteriology tenable at the London Hospital Medical College. The Senate invite applications for the University chair of Pathology tenable at the Middlesex Hospital Medical School. The salary will be £800 a year. Applications, accompanied by copies of not more than three testimonials and the names of not more than three persons to whom reference may be made, should be received not later than the first post on Tuesday, Jan. 27th, at the University, South Kensington, S.W. 7, by the Academic Registrar, from whom further particulars may be obtained. Twelve copies of all documents must be furnished, and envelopes should be marked "Chair of Pathology." An additional First Examination for Medical Degrees will be held in March, commencing on Monday, the 22nd. Applications for forms of entry must be made to the Academic Registrar, at the University, before Feb. 18th.

Advanced Lectures in Physiology.—The following courses of Advanced Lectures in Physiology, recognised by the University of London as advanced lectures which a candidate at the B.Sc. Honours Examination may name for part of his examination, have been arranged for the second term of the session 1919–20: (1) "Physiologically Balanced Solutions," eight lectures by Mr. W. L. Symes, M.R.C.S., in the Physiological Laboratory of the University, South Kensington, on Tuesdays, at 5 P.M., beginning on Jan. 27th. (2) "The Reaction of the Blood and Acidosis," eight lectures by Dr. J. W. Trevan, at St. Bartholomew's Hospital, on Wednesdays, at 4.30 P.M., beginning on Jan. 28th. (3) "The Regulation of Respiration," eight lectures by Dr. M. S. Pembrey and Dr. J. H. Ryffel, at Guy's Hospital, on Thursdays, at 4.30 P.M., beginning on Jan. 8th. These courses of lectures are addressed to advanced students of the University and to others interested in the subjects dealt with, and admission is free, without ticket.

The next annual congress of the Ophthalmological Society of the United Kingdom will be held on Thursday, Friday, and Saturday, April 29th and 30th, and May 1st, 1920, under the presidency of Mr. J. B. Story. The arrangements include meetings at the Royal Society of Medicine, 1, Wimpole-street, London, at the Royal London Ophthalmic Hospital, City-road, E.C., and at St. Margaret's Hospital, Leighton-road, N.W., the special hospital of the Metropolitan Asylums Board for cases of ophthalmic neonatorum. Among the subjects to be discussed are "Diabetes in Relation to Diseases of the Eye," and "The Prevention and Treatment of Ophthalmia Neonatorum," and members desirous of reading papers, showing cases, or taking part in the discussions, are requested to communicate as soon as possible with Mr. F. A. Juler, 24, Cavendish-square, London, W. 1. Papers and communications, subject to the judgment of the council, will be printed in full in the Transactions. Members are reminded that under the by-laws papers must not exceed 20 minutes in length and subsequent speeches 10 minutes, and that all communications must be typewritten.

Royal College of Surgeons of England.—Six Hunterian lectures on John Hunter's Observations and Discoveries in Anatomy and Surgery, illustrated by his specimens and preparations, will be delivered in the theatre of the College in Lincoln's Inn-fields, by Professor Arthur Keith, Conservator of the Museum, at 5 P.M. on each of the days mentioned:—I., Monday, Jan. 19th: His Contributions to Our Knowledge of the Heart and Blood-vessels. II., Wednesday, Jan. 21st: His Contributions to Our Knowledge of the Lungs and Pleuræ. III., Friday, Jan. 23rd: His Contributions to Our Knowledge of the Alimentary System. IV., Monday, Jan. 26th: His Contributions to Our Knowledge of the Kidneys, Bladder, and Urethra, and Diseases Connected with these Structures. V., Wednesday, Jan. 28th: His Contributions to Our Knowledge of the Genital and Reproductive Systems. VI., Friday, Jan. 30th: His Contributions to Our Knowledge of the Eye, Ear, and Nose.

West London Medico-Chirurgical Society.—A clinical meeting will be held to-day (Friday, Jan. 9th), at 8 P.M., in the society's rooms, West London Hospital, when Mr. W. H. Trethowan will show Six Cases of Bone Graft (from the Shepherd's Bush Special Surgical Hospital).

Royal Institution.—On Tuesday next (Jan. 13th), at 3 P.M., Sir Johan Cadman will deliver the first of two lectures at the Royal Institution on (1) Modern Development of the Miner's Safety Lamp; (2) Petroleum and the War. The Friday evening discourse on Jan. 16th at 9 o'clock will be delivered by Sir James Dewar on Low Temperature Studies, and on Jan. 23rd by the Hon. Sir Charles Parsons on Researches at High Pressures and Temperatures.

The Tuberculosis Society.—The adjourned joint meeting of this society and the Association of School Medical Officers will be held on Monday, Jan. 12th, at the rooms of the Medical Society of London, 11, Chandos-street, W., at 7.30 P.M., when the discussion on the Various Aspects of Tuberculosis as Affecting Child Life will be resumed by Dr. F. W. Higgs, Dr. Letitia Fairfield, Dr. Jane Walker, Dr. J. Watt, and others.—On Jan. 19th, at 8 P.M., Sir Henry Gauvain will read a paper on Surgical Tuberculosis from the Point of View of the Tuberculosis Officer.

Scottish Otological and Laryngological Society.—The society met in the Western Infirmary, Glasgow, on Dec 13th, 1919, the President, Dr. W. T. Gardiner, in the chair. The President showed a patient with total deafness associated with vertigo; the vertigo preceded the deafness by three weeks, the deafness coming on suddenly. Dr. R. P. Mathers showed an ex-soldier suffering from stenosis of the trachea following a bullet wound. Dr. A. A. Gray gave a demonstration illustrating the comparative anatomy of the membranous labyrinth. Dr. W. S. Syme showed a man whose larynx he had removed nearly two years ago for malignant disease; there had been no recurrence, and the man had developed a good pharyngeal voice. Dr. James Adam showed a woman with a growth of the hypopharynx of 13 years' duration, which had twice disappeared under radium and recurred. He also raised the question whether, in all cases of purulent rhinitis in children which fail to respond to a few months of ordinary treatment, the maxillary, like the mastoid antrum, should be explored. A discussion followed, which it was decided to continue at a future meeting. Dr. Kerr Love read a short paper on electrical aids to hearing, based on an experiment in the case of 70 deaf children.

The Mental Hospital Service of the London County Council.—The London County Council invite applications from qualified medical men for the appointments of fifth and sixth assistant medical officers in the London County Mental Hospital Service. There are vacancies at present for fifth assistant medical officers at Banstead Mental Hospital, Banstead, Surrey; Cane Hill Mental Hospital, Coulsdon, Surrey; Long Grove Mental Hospital, Epsom, Surrey; and for sixth assistant medical officers at Banstead Mental Hospital; Bexley Mental Hospital, Bexley, Kent; Cane Hill Mental Hospital; Claybury Mental Hospital, Woodford Bridge, Essex; Colney Hatch Mental Hospital, New Southgate, N.; Hanwell Mental Hospital, Hanwell, W.; Long Grove Mental Hospital. The remuneration attached to each appointment is at the rate of £300 a year, rising by £25 a year to £400 a year, and war bonus and a percentage addition have been granted by the Council, amounting to from £130 to £153 a year in addition to the scale salary. The question of the continuation or otherwise of the grant is under consideration by the Council. The appointments are pensionable. Candidates should not exceed 35 years of age. Forms of application, containing particulars of other conditions of appointment, can be obtained from the Asylums Officer, London County Council, 13, Arundel-street, Strand, London, W.C. 2, to whom a stamped addressed foolscap envelope should be sent for reply.

Mr. Joseph Watson, of Wetherby, has given £50,000 to the Leeds General Infirmary as a New Year's gift, on condition that the sum of £10,000 shall be invested and the proceeds devoted to a nurses' pension fund.

HUMANISED MILK AND PROFITEERING.—Recently at Exeter a local dairy was brought before the Profiteering Committee for charging 1*s.* 6*d.* per pint for humanised milk. The committee decided the charge was too much, and ordered that 3*d.* per pint should be refunded.

BATH PENSIONS HOSPITAL.—The Bath War Hospital has been acquired by the Ministry of Pensions for the treatment of discharged and disabled soldiers. The institution will be a centre for the treatment of disabled pensioners, and is to be known as the Bath Pensions Hospital. The commandant will be Lieutenant-Colonel Milne Thompson.

BRISTOL MEDICAL CHARITIES.—The voluntary medical institutions of the city are faced by considerable financial difficulties. In the local press the secretary to the Royal Infirmary points out the great increase in the cost of equipment; the secretary to the General Hospital, which is usually regarded as holding the soundest financial position of all the hospitals, says that the adverse balance is not far short of £10,000; while the Bristol Dispensary is also in great difficulties. The Children's and Eye Hospitals are believed to be contemplating rebuilding or extension schemes. Having regard to these conditions and the urgent need for improvement in many aspects of hospital work, the Lord Mayor of Bristol has decided to consider the hospital problem as a whole. There is reason to believe that this decision will meet with a cordial welcome from the various institutions, whose administrative and medical staffs are anxious to find some means of enhancing efficiency by coöperation.

ST. GEORGE'S HOSPITAL.—Dr. Robert Donaldson, F.R.C.S., D.P.H., pathologist and bacteriologist to the Royal Berkshire Hospital, has been appointed pathologist and curator of the museum at St. George's Hospital. This appointment was held by the late Dr. R. Salusbury Trevor, and since he died the work of the curator has been carried on by Miss Helen Ingleby, M.R.C.P., and Sir Humphry Rolleston, K.C.B., has been supervising the pathological laboratory as an honorary duty. The combined post will now be filled by Dr. Donaldson, who during the war was bacteriological specialist to the war hospital laboratory at Reading.

PRESENTATION TO A MEDICAL MAN.—An interesting ceremony recently took place at the Norfolk War Hospital (which has now resumed its normal function as the Norfolk County Asylum), when a presentation was made to Dr. David Thomson, C.B.E., by the permanent heads of departments of the hospital. The presentation, consisting of an illuminated address and an aneroid barometer, was made by the matron, Miss Hamer, as senior officer, in a felicitous little speech, in which she expressed the confidence felt by all the members of the staff in so able and enthusiastic a commanding officer. She stated that during the four and a half years the hospital was open 45,000 sick and wounded soldiers had been under treatment in the wards. A bouquet was presented to Mrs. Thomson, and Dr. Thomson, in reply, said that the highest praise and honour to which any man could attain was the appreciation of his fellow workers.

THE LATE MR. G. C. SEARLE.—George Clement Searle, M.R.C.S., L.S.A., died at Totnes, Devon, on Dec. 16th last, in his seventy-fifth year. Mr. Searle was one of the best-known medical men in South Devon, and had practised at Brixham, Devon, for over 40 years, but had retired some years ago. He was formerly medical officer of health for Brixham, and held several other public appointments. Mr. Searle, who was a prominent Freemason, took great interest in all local matters, was at one time chairman of the School Board, and later chairman of the school managers at Brixham.

THE LATE DR. E. T. COX, OF HOVE.—Dr. Ernest Tom Cox, who died on Dec. 21st, 1919, at his residence in Hove, where he had been in practice for more than 25 years, was an Aberdeen medical graduate, taking his M.B., C.M. in 1889, and his M.D. four years later. He practised in association with various colleagues in the Hove district. Among a number of public appointments he was surgeon to the East Sussex Constabulary, and was a captain in the R.A.M.C. (T.). He had held the highest offices in several lodges of Freemasons, was the founder of one lodge and one of the original members of another, and had the distinction of being Provincial Grand Senior Warden in the Sussex Province. His death at 51 years of age will be widely felt in the district.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than* 9 *o'clock on the Thursday morning of each week, such information for gratuitous publication.*

ALDERSON, G. C., M.B., B.C., F.R.C.S. Eng., has been appointed Surgeon to the Coventry and Warwickshire Hospital.

BOWES, E. S., L.R.C.P., M.R.C.S., Medical Officer for the Totnes District and Workhouse, by the Totnes (Devon) Board of Guardians.

DOHERTY, M. A., M.B., M.R.C.S., Honorary Assistant Obstetrician to the Elizabeth Garrett-Anderson Hospital Euston-road.

ROSS, E. A., M.D. Cantab., M.R.C.P. Lond., Honorary Clinical Pathologist to the Royal Hampshire County Hospital, Winchester.

SMURTHWAITE, H., M.D., B.S. Durh., Assistant Surgeon to the Gloucestershire Royal Infirmary and Eye Institution.

TYLER, M. F., M.B., Medical Officer for the Dartmouth, Dittisham, and Kingswear District by the Totnes (Devon) Board of Guardians.

WAYLEN, G. H. H., B.Ch. Cantab., L.R.C.P., M.R.C.S., Medical Officer of the Third District and Workhouse Infirmary, by the Devizes (Wilts) Board of Guardians.

WILKINSON, A. G., M.B., Ch.B., D.P.H., D.T.M., Senior Medical Officer in Charge of the Tropical Section, Ministry of Pensions Hospital, Orpington, Kent.

Belfast Infirmary: HILL, T. E., M.B., B.Ch., B.A.O. Dub., House Surgeon; and HALL, R., jun., M.B., B.Ch., B.A.O. Belf., CLEARKIN, J. M., M.B., B.Ch., B.A.O. Belf., and WILSON, G., L.R.C.P. & S., L.M. Irel., House Physicians.

Certifying Surgeons under the Factory and Workshop Acts: TURNER, R. T., M.D. Vict. (Nantwich), WHITEHEAD, B., M.R.C.S., L.R.C.P. Lond. (Downton), JAMESON, J. E., M.B., B.Ch. Dub. (Kingston), CLEGG, E. A., M.R.C.S., L.R.C.P. Lond. (Gosport), SMITH, W. A., M.B., C.M. Aberd. (Darwen).

Vacancies.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Tuesday, Jan. 13th.

PSYCHIATRY (Hon. Secretaries—Bernard Hart, G. F. Barham) at 5 P.M.
Papers:
Dr. E. W. Scripture: The Nature of Epilepsy.
Dr. H. Crichton Miller: The Rôle of the Endocrines in the Production of Mental Disorder.

Wednesday, Jan. 14th.

HISTORY OF MEDICINE (Hon. Secretaries—Arnold Chaplin, F. G. Crookshank): at 5 P.M.
Papers:
Mr. S. P. Vivian: Thomas Campion, Doctor of Phisicke, 1567–1620.
Canon Westlake: The Gild of our Lady of Rouncyval.

Thursday, Jan. 15th.

DERMATOLOGY (Hon. Secretary—Henry MacCormac): at 5 P.M.
Cases: (4.30 P.M.) will be shown by—
Dr. H. W. Barber: Recurrent Ulceration of the Skin, apparently due to a Diphtheroid Bacillus; and others.

Friday, Jan. 16th.

OTOLOGY (Hon. Secretaries—H. Buckland Jones, Lionel Colledge); at 5 P.M.
Short Paper:
Dr. A. A. Gray: A Few Anatomical Details of the Anatomy of the Vestibule, not previously described.
Cases and Specimens will be shown by—
Mr. E. D. D. Davis, Mr. J. S. Fraser and Dr. J. K. Milne Dickie, Mr. Somerville Hastings, Mr. Richard Lake, and others.

ELECTRO-THERAPEUTICS (Hon. Secretaries—Walter J. Turrell, Stanley Melville): at 8.30 P.M.
Paper:
Mr. C. Thurstan Holland: Lessons of the War.

THE TUBERCULOSIS SOCIETY AND THE ASSOCIATION OF SCHOOL MEDICAL OFFICERS (JOINT MEETING), at the Rooms of the Medical Society, 11, Chandos-street, Cavendish-square, W.

MONDAY, Jan. 12th.—7.30 P.M., Adjourned Discussion on the Various Aspects of Tuberculosis as Affecting Child Life. Lieut.-Col, F. W. Higgs, C.B.E., Lieut.-Col. Lætitia Fairfield, C.B.E., Dr. Jane Walker, Dr. Watt, and others are expected to take part in the discussion.

RÖNTGEN SOCIETY, at the Royal Photographic Society's House, 35, Russell-square, W.C.

TUESDAY, Jan. 13th.—7 P.M., General Meeting. Discussion on Some Aspects of Radiology and Radiometallography, opened by Major G. W. C. Kaye, O.B.E.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, Cavendish-square, W.

FRIDAY, Jan. 16th.—8.30 P.M., Discussion on Bacillary Dysentery, opened by Dr. P. Manson-Bahr.—Paper:—Read for Dr. T. Clarke (Penang): Fleas as the Probable Carriers of Rheumatic Fever.—Read for Dr. F. Roux: Note on the Treatment of Malaria and Blackwater Fever.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

UNIVERSITY OF LONDON.

Advanced Lectures in Physiology to Students of the University and others interested in the subject.

A Course of Eight Lectures on the Regulation of Respiration will be given by Dr. M. S. Pembrey and Mr. J. H. Ryffel at Guy's Hospital, Borough, S.E.

THURSDAY, Jan. 15th.—4.30 P.M., Lecture II.

LONDON HOSPITAL MEDICAL COLLEGE (UNIVERSITY OF LONDON), Mile End, E.

A Course of Instruction on the Diseases of Children, open to Post-Graduates and to Students of the Hospital. (The lectures will be illustrated by lantern slides.)

MONDAY, Jan. 12th.—9.15 A.M., Lecture I.:—Dr. Thompson: Organic and Functional Nervous Diseases, Meningitis and Mental Deficiency. (At the Anatomical Theatre.)

WEDNESDAY.—10 A.M., Clinical Demonstration:—Dr. Miller. (At the Children's Out-patient Department.)

SATURDAY.—10.15 A.M., Lecture II., Dr. Hutchison: General Diseases. (At the Anatomical Theatre.)

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

TUESDAY, Jan. 13th.—4.30 P.M., Opening Address:—Sir Humphry Rolleston, K.C.B.: The Uses and Methods of Application of Post-Graduate Teaching.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART POST-GRADUATE COURSE, Westmoreland-street, W.

MONDAY, Jan. 12th.—11 A.M., Out-patients: Dr. Goodall. 2 P.M., In-patients: Dr. Moon.

TUESDAY.—2 P.M., Out-patients: Dr. R. Wells. 3 P.M., In-patients: Dr. Gibbes.

WEDNESDAY.—2 P.M., Out-patients: Dr. Moon. 5.30 P.M., Lecture:—Dr. Hamill: Præcordial Pain.

THURSDAY.—10 A.M., In-patients: Dr. Hamill: 2 P.M., Out-patients: Dr. Price.

FRIDAY.—2 P.M., Out-patients: Dr. Gibbes. 2.30 P.M., In-patients Dr. Wells.

SATURDAY.—10.30 A.M., In-patients: Dr. Hamill.

ROYAL INSTITUTE OF PUBLIC HEALTH, in the Lecture Hall of the Institute, 37, Russell-square, W.C.

Special Course of Lectures and Demonstrations on Tuberculosis for Medical Men and Women qualifying to become Tuberculosis Officers, General Practitioners, and others. Bacteriological Demonstrations will be given in the Laboratories of the Institute, and visits arranged to Sanatoriums, Tuberculosis Dispensaries, &c.

THURSDAY, Jan. 15th.—5 P.M., Lecture I.:—Prof. E. W. Hope: Schemes and Methods in Tuberculosis Work.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE CLINIC.

TUESDAY, Jan. 13th.—4.30 P.M., Lecture:—Mr. E. D. Telford: Treatment of Spinal Caries.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, W.C. 1.

MEDICAL SCHOOL.

MONDAY, Jan. 19th.—2–3.30 P.M., Out-patient Clinic: Dr. Collier. 3.30 P.M., Dr. S. A. Kinnier Wilson: Examination of the Nervous System and Interpretation of Physical Signs. I.

TUESDAY, Jan. 20th.—2–3.30 P.M., Out-patient Clinic: Dr. Grainger Stewart. 3.30 P.M., Ward Cases: Dr. James Taylor.

WEDNESDAY, Jan. 21st.—2 P.M., Mr. Scott: Tinnitus aurium. 3.30 P.M. Dr. Greenfield: Pathological Demonstration.

THURSDAY, Jan. 22nd.—2–3.30 P.M., Out-patient Clinic: Dr. Farquhar Buzzard. 3.30 P.M., Dr. S. A. Kinnier Wilson: Examination of Nervous System and Interpretation of Physical Signs. II.

FRIDAY, Jan. 23rd.—2–3.30 P.M., Out-patient Clinic: Dr. Gordon Holmes. 3.30 P.M., Ward Cases: Dr. Hinds Howell.

SATURDAY, Jan. 24th.—9 A.M., Surgical Operations.

Fee for Post-Graduate Course £5 5*s*. C. M. HINDS HOWELL, Dean.

THE MEDICAL PROFESSION AND THE PEERAGE.

BY S. D. CLIPPINGDALE, M.D.

Sir Bertrand Dawson's elevation to the peerage lends interest to the question how far the medical profession and the peerage have hitherto been associated by either actual grant or direct descent. A glance over the authorities reveals the following instances, no claim being implied that the list is complete.

Addington (*Sidmouth*).—The first Viscount Sidmouth, Speaker of the House of Commons in the time of George III., was son of Dr. Henry Addington, of Upper Ottery, co. Devon.

Alexander (*Burgh*).—Dr. Reginald Gervaise Alexander succeeded on July 20th, 1919, in establishing to the satisfaction of the House of Lords his claim to be co-heir to the ancient barony of Burgh, created in 1437, his claim to be co-heir also to the dormant baronies of Cobham and Strabolgi being reserved for future consideration.

Barwick (*Sherbourne*).—The only daughter and heiress of Dr. Peter Barwick, physician to Charles I. and Charles II., and one of the few doctors who remained in London during the Great Plague, by marrying Sir Ralph Dutton of Sherbourne became ancestress of the Duttons, Barons Sherbourne.

Bickersteth (*Langdale*).—Henry Bickersteth, son of a surgeon practising in Kirkby Lonsdale, was himself first a physician (M.D. Camb.), then a lawyer. Rising in the latter capacity to the position of Master of the Rolls, he, in 1836, was created Baron Langdale. This peerage is now extinct.

Bray (*Braye*).—Sir Richard Bray, said to have been physician to Henry VI., and who lies interred at Worcester Cathedral, was grandfather of Sir Edmund Bray, summoned to Parliament as Baron Bray, 21 Henry VIII., ancestor of the present Lords Braye of Eaton Braye.

Dalrymple (*Stair*).—The Hon. Thomas Dalrymple, M.D., physician in Scotland to King William and Queen Mary, was son of the first Viscount Stair.

De Fernham (*Durham*).—Nicholas de Fernham, physician to Henry III., becoming weary of Court life, retired, and, being an ecclesiastic, was made Bishop of Durham.

Denman (*Denman*).—Baron Denman, of Dovedale, Lord Chief Justice of England from 1832 to 1850, was the son of an eminent obstetric physician, Dr. Thomas Denman.

Douglas (*Glenbervie*).—Sylvester Douglas, who studied medicine at Aberdeen and afterwards practised as an apothecary, exchanged physics for politics, and, becoming eminent as a diplomatist, was, in 1800, raised to the Irish Peerage by the title of Baron Glenbervie, on which occasion Sheridan wrote:—

> "Glenbervie, Glenbervie!
> What's good for the scurvy?
> Let your old trade ne'er be forgot,
> For arms you should quarter
> A pestle and mortar,
> And for crest take a spruce gallipot."[1]

Fairfax (*Fairfax of Cameron*).—John Contée Fairfax, M.D. of Fairfax County, Virginia, a large landed proprietor, wa eleventh Baron Fairfax of Cameron in the Peerage o Scotland, a 1627 creation.

Finlay (*Finlay*).—Sir Robert Bannatyne Finlay graduate in medicine at Edinburgh University before his call to th Bar in 1867. He became Lord Chancellor in 1916, with barony for his lifetime.

Foster (*Ilkeston*).—The Right Honourable Sir Walter Foster M.D., was in 1910 created Baron Ilkeston of Ilkeston, in th county of Derby.

Holland (*Knutsford*).—The eldest son of Sir Henry Holland Bart., Physician to Queen Victoria, was, in 1895, create Viscount Knutsford.

Howard (*Wicklow*).—Dr. Ralph Howard, President of th Royal College of Physicians, Ireland, in 1674, acquired fron the Duke of Ormonde the estate of North Arklow, co Wicklow. This estate was confiscated by James II., bu restored by William III., and the doctor's grandson create Viscount Wicklow and Baron Clonmore.

James (*James of Hereford*).—The late Baron James o Hereford was the son of Mr. Philip Turner James, surgeon of Hereford.

Lister (*Lister*).—The great surgeon was raised to th peerage as Baron Lister of Lyme Regis, in the county Dorset, Feb. 6th, 1897. He left no heir to the barony.

Lister (*Ribblesdale*).—The Listers, Barons Ribblesdale, ca claim for their pedigree three notable medical men, D

---

[1] Moore's Life of Sheridan.

Edward Lister, physician to Queen Elizabeth ; Sir Mathew Lister, physician to James I.; and Dr. Martin Lister, physician to Queen Anne.

Morley (*Morley of Blackburn*).—Viscount Morley of Blackburn is the son of Mr. Jonathan Morley, surgeon, of Blackburn.

Pemberton (*Kingsdown*).—Edward Pemberton, M.D., of Warrington, was grandfather of the first Baron Kingsdown, a peerage now extinct.

Playfair (*Playfair*).—The first Baron Playfair, of St. Andrews, in the county of Fife, so created in 1892, was the son of Dr. George Playfair, Inspector-General of Hospitals, Bengal.

Primrose (*Rosebery*).—The Earl of Rosebery, Hon. F.R.C.S. Eng. and Edin., is the lineal descendant of Gilbert Primrose, or Prymross, surgeon to James I. and VI., and first President of the Royal College of Surgeons, Edinburgh. At the recent tercentenary celebration of the college Lord Rosebery, who attended, exhibited the pestle and mortar which had belonged to his medical ancestor.

Petty (*Shelburne*), *Petty* (*Lansdowne*).—Sir William Petty, who was physician to Charles I., and whose wife was created Baroness Shelburne, had two sons, who became first and second Barons Shelburne respectively. They died, however, without issue. Sir William's daughter and heiress married Thomas Fitzmaurice, Earl of Kerry, and so created the Petty-Fitzmaurice family, of which the present Marquis of Lansdowne (Sir Charles Petty-Fitzmaurice) is the representative. Concerning this marriage a cynical member of the family said that the doctor's daughter brought into it "whatever degree of sense may have appeared in it and whatever wealth is likely to remain in it."

Sanders (*Melville*), *Sanders* (*Westmorland*).—Dr. Richard Huck Sanders, physician to the forces in the reign of George III., left two daughters, co-heiresses of his wealth. The elder of these ladies married the second Viscount Melville and became ancestress of the succeeding Viscounts Melville. The younger lady became the second wife of the tenth Earl of Westmorland, whose honours, however, descended to the issue of his first wife.

Singe-Hamilton (*Abinger*).—The Honourable Mrs. Singe-Hamilton, M.D., the first lady member of the peerage to become a member of the medical profession, is a daughter of the third Baron Abinger.

Sloane (*Cadogan*).—Sir Hans Sloane's daughter married the second Baron Cadogan, to whom she conveyed the Manor of Chelsea, purchased by her father as a result of his successful practice.

Smithson (*Northumberland*).—Sir Hugh Smithson, Bart., who had practised as an apothecary in Hatton Garden, having married the Percy heiress was created, in 1749, Earl, and, in 1766, Duke of Northumberland.

Somerville (*Somerville*).—Dr. William Somerville, husband (and cousin) of Mary Somerville, the talented authoress, and physician to Chelsea Hospital, was directly descended from the Barons Somerville of Cambusnethan, ennobled as early as 1442.

In addition to these, Dr. Bathust, physician to Oliver Cromwell, and Sir William Waldegrave, physician to James II., are known to have been members of the Bathust and Waldegrave peerage families, respectively, but their position in the pedigrees of those families is not clear.

THE NEW DISABLEMENT PENSIONS.

A FURTHER report of the Select Committee on Pensions issued on the last day of 1919 (H.M. Stat. Office, price 3*d.*), suggests a generous increase in the scale of disablement pensions for officers and for the dependents of both officers and men.

The recommendation contained in the first report of the Select Committee (July 28th, 1919) that soldiers' pensions should, like sailors', be awarded as a statutory right and not by way of bounty was accepted by the Government, and is embodied in the War Pensions Act of 1919. The exclusion of widows and dependents from the statutory recognition, since found to be a hardship, will be made good if the recommendation contained in the present report is put in force.

The War Office, the Admiralty, and the Air Ministry have recently issued new Orders improving the rates of service retired pay. The present report reconsiders the provisions for disability in the light of these new regulations. Officers who have already served in the war and retired prior to September, 1919, are given the benefit of the new rates. The new service rates professedly allow for the increased cost of living, and are to be subject to revision after five years to an extent not exceeding 20 per cent., and thereafter at intervals of three years.

The report proceeds :—

> The natural basis to take for officers qualified for service retired pay is the new scales of such retired pay. But these scales only apply in the case of the Army to those with 15 years' service, and in the case of the Navy and Air Force to those who are 40 years of age and over. For officers not so qualified we propose to take as a basis: (i.) for the Army and Air Force, £200 for a Lieutenant-Colonel, £170 for a Major, and for Captains and Subalterns a graduated scale graded down from £140 for 14 years' service, and with a minimum of £120 for a Captain and £70 for a Lieutenant and 2nd Lieutenant; and (ii.) for Lieutenants and Lieutenant-Commanders of the Navy the new invaliding scale varying with service in the rank laid down in the Admiralty Order.
>
> There is no provision in the Admiralty Order either for Sub-Lieutenants or for Commanders of the Royal Navy. To meet the difficulty we recommend that £70 be the scale for the Sub-Lieutenant, thus placing him on an equality with the Lieutenant of the Army, to whom he corresponds in rank, and for the Commander the new invaliding scale applicable to Lieutenant-Commanders with increments of £10 for each year of service on the date of promotion to Lieutenant-Commander and a flat-rate addition of £50 for rank.
>
> As to the addition to be made for disablement, the present addition is £100 for 100 per cent. disablement ; but to this at present must be added the 20 per cent. war bonus reckoned on the temporary officers' scales, which amount to £35 for 100 per cent. disablement in the case of a Captain or Subaltern, £45 in the case of a Major, and £50 in the case of a Lieutenant-Colonel. So far as the retired pay element is concerned, bonus may now be regarded as included in the new basic scales. But so far as the disablement element is concerned, it is necessary to augment this, and we recommend an increase of the present scale by 50 per cent., making it £150 for 100 per cent. disablement, and that a proportionate addition be made for the lower grades.
>
> The new Army rates of half-pay show a very great increase, and we recommend that for regular officers of the Army these rates, without any additions, should be accepted as minimum rates for disability. They will be liable to adjustment after five years, and should be limited to the substantive rank held by the officer at the time of his retirement.

The result of the foregoing recommendations will be to make the disablement pensions to be awarded to regular officers as shown in the following table:—

TABLE A.—ARMY.

Rank.	Total service.	Service in rank.	Present.	Proposed.
I.—*100 per cent. Disablement.*

Lt.-Comr. (age 34)	14	3	198	292†
Lt.-Comr. (age 42)	21	10	323	465
Commander (age 34)	14	3*	225	365†
Commander (age 42)	21	7	325	465

* Includes service as Lieutenant-Commander. † Half-pay rates.

The rates for temporary officers disabled in the late war work out in the case of 100 per cent. disablement at amounts varying from £210 for the 2nd Lieutenant to £300 for the Lieutenant-Colonel.

In regard to disability and deaths as a result of earlier campaigns, the report accepts the principle that those disabled in previous wars and their dependents, both officers and men, should, if already in receipt of disablement pension or allowance, receive the benefit of all the improved rates granted to officers and men and their dependents in the present war.

BOOKS OF REFERENCE.

THE fifty-second annual issue of *Whitaker* (1920. 12, Warwick-lane, London. Pp. 1020. 6*s.*) reverts to the more complete enumeration of facts and figures which characterised it in the pre-war days ; the Service lists again appear, and statistics which would have given information to the enemy are reintroduced. New Government departments are also to be found in this volume, and the Ministry of Health receives liberal treatment in the way of reference. At this time of day there is no need to describe the contents of *Whitaker*, but mention may be made of a new section dealing with "Questions of the Day" and of special articles devoted to sport, workmen's compensation, meteorology, women's work, aviation and science and invention, and an improved and extended section on banking. For the rest the book is still the indispensable work of reference it has always been.

The *New Hazell Annual and Almanack, 1920* (Edited by T. A. Ingram, LL.D. London: Henry Frowde and Hodder and Stoughton. Pp. 940. Price 6*s*.), is another book which, on account of its utility, finds a place in every office and library, containing the most recent and authoritative information concerning the British Empire, the nations of the world, and the important topics of the day. Among the new features of the present issue are the articles on the peace treaties with Germany, Austria, and Bulgaria, which are fully dealt with, while the text of the Covenant of the League of Nations is set out in full, as well as Labour's Charter under the League. The article on Pensions and Separation Allowances treats the subjects very fully. Scientific and industrial research also receive attention, and among the maps which illustrate the *Annual* are two showing the new Germany and the new Austria.

LONGEVITY.

IN the *Evening News* (London) of Dec. 29th, 1919, there appears a reproduction of a tablet on a wall of the parish church of Shifnal, Salop, showing two instances of extraordinary longevity. The first name on the tablet is that of William Wakley, who was born on May 1st, 1590, and was buried on Nov. 28th, 1714, being therefore 124 years of age. The date and place of his baptism and burial appear to have been verified. This William Wakley was believed by the late Mr. Thomas Wakley, senior, to have been his grandfather's grandfather, and the dates make the theory just possible, crediting William and the two succeeding generations with unusual prolongation of vigour. The Thomas Wakley who founded THE LANCET was born in 1795, his father, Henry, of Membury, having been born in 1750.

THE POSITION OF BRITISH BUTTER.

DAIRY products include butter and cheese (and rarely milk-sugar), and the starting-point of all is, of course, milk. In the time of plentiful supplies or of an excessive output the manufacture of these products is an economically sound proceeding, though we cannot understand why the milk-sugar is seldom recovered but lost in the whey, though it is the most abundant solid constituent of milk, the proportions being—milk-sugar 5 to 6 per cent., casein (cheese) 3·3 per cent., and fat (cheese and butter) 3·5 to 4 per cent. With a shortage of milk and high prices ruling the raw material in its entirety goes to the consumer, and British cheese and butter-making are for the time in abeyance. That is why no butter has been made in this country for some time, and what little butter is available for distribution comes from sources beyond these shores. So long as milk remains at its present inflated price the dairy industry will discard the making of solid milk products, unless a very high price is offered for them. Imported butter is still controlled and rationed, and these regulations are to be continued, but British butter is to be relieved from control in February. With milk realising a price of 3*s*. 3*d*. per gallon to the producer, the chances are that when the restriction in regard to the supply of British butter is withdrawn its price may mount to anything.

PUBLIC HEALTH AT GIBRALTAR IN 1918.

THE total civil population of Gibraltar is estimated to be 17,963, of whom 14,511 dwell in "the city," giving a density of 139 persons per acre in this area. The density of population in London, within the area dealt with by the Registrar-General, was in 1911 at the rate of 60·43 per acre. The borough of Bethnal Green had a density of 173 per acre. Gibraltar, therefore, though extremely crowded, is not in a worse condition in this respect than some town populations in our own country. But about 10,000 aliens and 1500 British residents in La Linea (the nearest point in Spain, about half a mile to the north across the neutral ground) come into the city daily for the purposes of their employment. As regards infectious diseases, the total number of cases was 159. Of enteric fever there were 31 cases and 3 deaths and of measles 25 cases and 2 deaths. The total zymotic death-rate only amounted to 0·455 per 1000. Colonel G. Dansey-Browning, C.B.E., A.M.S., who presents the report, as medical officer of health, draws special attention to the incidence of pulmonary tuberculosis, of which there were 39 cases with 37 deaths. The cases were more numerous than in either of the three preceding years, and the number of deaths greater than in any year of the decennium (1909–1918). He considers the figures to be very unsatisfactory, and to show that the marked improvement which coincided with better housing in the last decade has not been maintained. The administrative measures adopted in regard to this disease are admirable. Each case notified is inquired into, the needful precautions in regard to infection are explained, assistance given if necessary, both in the way of food, &c., and by accommodation of the patient at the tuberculosis home, or by treatment at the dispensary. The average monthly number of patients attending the dispensary was 49, and the average monthly number of visits paid to the patients' homes was 40; while five families have been provided with free quarters at the home, and 75 families assisted with food, and with money if needed. Of the 31 enteric cases, 9 had probably contracted infection in Spain, 7 from contact with persons suffering from the disease in Gibraltar, 2 from eating shell-fish, and 3 from drinking polluted water. The alien water-seller, from whom these last-mentioned cases had been infected, happened to meet with an accident, and on admission to hospital was found to be suffering from ambulatory typhoid. All water-sellers now have to be examined and licensed. There was an entire absence of Mediterranean fever amongst the civil population for the first time since 1908; one soldier developed the disease three weeks after drinking brandy diluted with goat's milk whilst on pass in Spain. Since 1906 no goats have been allowed to be imported unless they are proved to have come from a non-infected herd, and all milk imported from Spain is boiled before being sold. Gibraltar suffered from two epidemics of influenza in 1918; these form the subject of a special report. The first outbreak lasted from the latter half of May to the beginning of July—that is, during the hot, dry weather—and was of a mild character; 8 deaths were recorded from influenza and 13 from pneumonia—21 in all. Colonel Dansey-Browning considers that the actual number of cases cannot have been less than 800. The second epidemic, from the beginning of September to the end of November, was much more severe; there were 76 deaths from influenza and 36 from pneumonia — 112 in all. Toxæmia, with or without albuminuria, was a frequent symptom; the actual number of cases is estimated to have been 6000—"that is to say, over 30 per cent. of the total civil population suffered in some form or other from influenza in 1918." Isolation, free ventilation, and disinfection were found to be effectual in checking spread. In the second period it became necessary to prohibit indoor public assemblies and wakes, and to restrict funeral ceremonies in churches. Colonel Dansey-Browning's report is very concise, and fully illustrated by tables of statistics in detail. It is evident that the greatest watchfulness is maintained over the sanitation of the fortress and city, and the health of the civil and military population.

THE TOXICITY OF WOOD ALCOHOL.

THE remarkable toxic properties of wood alcohol (methyl alcohol), referred to in our issue last week, claim wider attention, and there appears to be considerable misconception as to what wood alcohol really is. At all events, pure wood alcohol (CH_3OH) is not readily accessible to the public; in its more or less pure form it is used as a solvent for waxes and varnishes by the chemical manufacturer, by the analytical chemist, and by the microscopist in the preparation of certain aniline stains. Methylated spirit as we know it, and as it is employed in spirit lamps, is not wood alcohol, but a mixture of ordinary alcohol (ethyl) with an addition of 10 per cent. wood alcohol and a small quantity of mineral naphtha (light paraffin oil). The presence of the oil is shown on adding water to the spirit when it turns milky through separation of the oil. It is thus called "mineralised" or "denaturalised," but still contains about 90 per cent. of alcohol (ethyl) or rectified spirit, the chief factor of potable spirit. It is not usually the case that the lowest member of an homologous series is more toxic than its higher molecular relatives. Propyl alcohol (C_3H_7OH), for example, is more powerful than ethyl (C_2H_5OH), butyl (C_4H_9OH) than propyl, and amyl ($C_5H_{11}OH$) than any of them, and so the toxicity advances as CH_2 is added. According to Cushny, the symptoms of wood alcohol poisoning in man differ from those of ordinary spirits in the marked muscular weakness and defective cardiac action, which are followed by nausea, vomiting, coma, or delirium of a much more intense and persistent character than those seen in intoxication with ethyl alcohol. In a considerable number of cases the same observer records that death has followed from a single dose smaller than would have been fatal had ethyl alcohol been taken, and in some cases total and permanent blindness has followed or accompanied recovery. It is suggested that while ethyl alcohol undergoes complete combustion in the tissues, methyl alcohol is oxidised to formic acid and possibly to formic aldehyde, both of which are much more poisonous than the original alcohol. This explanation is plausible, so that the intense toxicity of methyl alcohol compared with that of ethyl alcohol may be due to incomplete combustion, just as poisonous carbon monoxide is given off by an imperfectly working fire or stove.

An Address

ON THE

APPLICATION OF WAR METHODS TO CIVIL PRACTICE.

Delivered before the Clinical Section of the Royal Society of Medicine on Jan. 9th, 1920,

BY SIR ANTHONY BOWLBY, K.C.B., K.C.M.G., K.C.V.O.,

SURGEON-IN-ORDINARY TO H.M. THE KING, ETC.

GENTLEMEN,—My absence from England when our session opened prevented me from acknowledging earlier my appreciation of your kindness in electing me to be your President, and I gladly do so now. I have always kept in mind during the war the question of the ultimate utilisation in civil surgery of that vast experience of wounds which can only be supplied by a great war; and I think that, while this is yet fresh in our minds, we should test some of those methods which thousands of British surgeons have learnt in various parts of the world.

"SHOCK" AND ITS PREVENTION.

It will be universally acknowledged that the first and most striking danger to the man wounded in war is "shock," and this condition is met with in a far higher percentage of men wounded in war than in those correspondingly injured in the occupations of peace. The reasons for this are sufficiently obvious, for the man injured in the workshop or the factory or on the railroad is not suffering from want of sleep or want of food and of water. He is not unduly exhausted by physical strain or by mental excitement, and when he is injured help is at hand quickly. The man injured in war is frequently suffering from some or all of these causes of exhaustion, and he is often thoroughly chilled after his injury through lying out in cold, wet, or even freezing weather. The shock of the soldier is, as a result, often quite out of proportion to the severity of his wounds, and is consequently not to be estimated accurately as true "wound shock" until these other factors have been eliminated by appropriate treatment. Unless this is kept in mind, it becomes exceedingly difficult to estimate the true value of remedial measures, for it will be found in war that complete rest, plenty of hot drinks, and plenty of warmth will in thousands of cases restore in a comparatively few hours men who were cold and pulseless on admission to hospital. I have always been convinced that the most important of all the remedies for shock is warmth, and that nothing takes its place. When this was appreciated, and when every casualty clearing station had arrangements for warming men by the introduction of hot air under the blankets, the majority of the badly shocked men went to sleep after a good drink and recovered with surprising rapidity.

It must be constantly kept in mind that the injury inflicted by rough transport may be as potent a cause of true wound shock as was the original gunshot wound itself, and it is therefore obvious that if this statement is as true as I believe it to be much of the wound shock can be obviated by sufficient care: first, in the early application of suitable splints, which should be employed in all severe injuries and not reserved for fracture cases alone; and secondly, by the supply of well-hung and well-warmed ambulance-cars.

It was partly by such simple and accessible methods as these that the condition of the wounded man was so greatly improved during the war, and it will be by the application in civil life of the knowledge we have gained that a like improvement will be obtained in peace.

Splints and ambulances.—I have been myself so convinced of the importance of care in the transport of injured men that, with the aid of the Army Medical Service and of the British Red Cross Society, I have arranged for the equipment with suitable splints of the motor ambulances which have been supplied to various parts of Great Britain, and arrangements are now being made to see that the ambulance drivers and orderlies are as thoroughly trained in the use of the "Thomas outfit" for fractured extremities as were our orderlies at the front in France. It is quite easy to train men who have no surgical knowledge at all so that they shall provisionally put up a fractured leg or thigh much better than the best surgeon could have done it before the war, and I believe that one result of what our experience has taught us is that in every country arrangements should be made to teach how badly wounded men may be taken even for great distances without further injury being inflicted upon them by the transit.

THE TREATMENT OF SHOCK.

So much for prevention of shock, but, as far as treatment is concerned, the practical deduction which is to be drawn from a consideration of our present knowledge of shock is that, isasmuch as the principal phenomena are loss of blood volume and fall of blood pressure, the obvious aim should be to restore these.

The treatment by rest, warmth, and taking of fluids is indicated in all cases, whatever more may be required, and morphia in moderate doses will be useful in allaying pain, anxiety, and excitement, and so encouraging sleep. In many cases nothing more is needed. The simplest method of increasing the blood volume is to administer fluids by the mouth, and as all soldiers in battle areas have only limited supplies of water to drink it should be accepted as an axiom that all wounded men always require drink as soon as they arrive at an aid-post or field ambulance.

Unfortunately, many patients with really severe shock are quite unable to keep down any fluid, and in that case rectal injections are often most useful. I believe it is true that both blood pressure and blood volume are more likely to remain permanently improved by gastric or rectal absorption of fluid than by the intravenous administration of the same quantity. It seems clear that the direct addition of fluids to the venous blood is not so good as the making of blood serum by the patient himself from fluid absorbed through a mucous membrane, but in many cases of severe shock, and in view of the fact that delay may mean disaster, it is often necessary to perform intravenous infusion as soon as the patient has been warmed and rested. We have learnt that normal saline solution is useless for this purpose, but it is the opinion of most observers (and it is mine) that Bayliss's solution of 6 per cent. gum arabic in normal saline is often of the greatest benefit in raising the blood pressure for long enough to carry the patient over the danger period.

In proportion as the shock conditions are due to excessive bleeding immediate infusion of blood is better than gum solution, and is undoubtedly indicated: not less than a pint should be introduced. There is no doubt that many lives were saved by this practice, and there is also no doubt that it was not until the surgeons of the United States Army joined the British casualty clearing stations in 1917, before Passchendaele, that blood transfusion became common. Its employment was subsequently utilised yet farther forward, and great benefit ensued when prepared citrated blood was sent up to the field ambulances when a battle was impending during the advance of the Allies in 1918, as it could safely be kept for from 12 to 18 hours or more before use. I would suggest that in future sterilised gum solution should be kept ready for use by operating surgeons and by all civil hospitals, and also that test sera for donors of blood should be regularly stocked, so that no delay may arise in the choice of a donor, for if such treatment is necessary at all it is certain that there will be no time to waste, as the experience of war has shown that if blood is transfused too late it is quite useless.

ANÆSTHETICS.

But if we have learnt much that is valuable about shock and its prevention and treatment, we must realise that after the patient had been pulled through with difficulty it was often necessary to operate as soon as possible and before sepsis had appeared upon the scene; so that no sooner had the patient been saved from the shock of his original injury than he was obliged to run the risk of operation shock. Still, where limbs were hopelessly shattered, or main vessels were torn, or the abdomen was shot through, &c., there was no choice left to the surgeon, who also knew that in many cases the rapid removal of a smashed limb resulted in great relief of symptoms. But operation generally meant anæsthetics, and here we were destined to learn a great deal that was new to us.

The Choice of an Anæsthetic.

With regard to the choice of an anæsthetic agent it may be conceded at once that for all slight operations on patients in good condition "open ether" was very often quite satisfactory. But when in wintry or wet weather very many of the wounded were already suffering from a bronchial catarrh ether was very liable to cause grave pulmonary complications, and it was not until we introduced the "Shipway apparatus" for warming the ether vapour that it could be safely administered in such cases. I would very strongly advocate that in the future warm ether vapour should be systematically employed as the better routine method where ether is used in civil practice, for it is not only less irritating to the lungs, it is also much less liable to cause severe vomiting. But in cases of shock neither chloroform nor ether is safe, for a careful record of blood pressure in operations during shock by Major Geoffrey Marshall showed conclusively that after the use of these anæsthetics, although the blood pressure might be high when the operation was finished, this was soon followed by a reactionary fall and death.

And not only is ether not a safe anæsthetic in shock, it is also very injurious if, as is so often the case, it causes nausea and sickness in men who need every ounce of fluid nourishment that can be given, for this sickness, if continued for some hours, will destroy the last chance of recovery for the shocked man.

Much had been expected from the intrathecal use of stovaine, but the sudden fall of blood pressure it caused proved it to be very dangerous to shocked men, and not so good as novocaine. Local anæsthesia was so tedious that it was not possible to use it as a routine method where patients were numerous. It was very useful in selected cases. There remained nitrous oxide and oxygen. The value of this agent in shock had been conclusively proved by Marshall in 1916, and his observations showed that under its influence extensive operations could be performed without any immediate or subsequent fall of blood pressure. Its use saved many lives, and in abdominal operations the very best results of all were obtained by combining it with infiltrative anæsthesia of the abdominal wall. By this combined method the gas and oxygen required was reduced to a minimum and the operator was not troubled by abdominal rigidity. It was by the use of this combination that Majors D. Taylor and G. Marshall at "Remy siding" succeeded in saving 74 patients in a consecutive series of 101 operations for perforating wounds of the abdomen, and I believe that these results were amongst the best obtained in the British Army during the war.

Very much more might be said of war anæsthesia did time permit, but I would urge that gas and oxygen should be supplied, together with suitable apparatus for all the Army Medical Services of the future, and I would also press upon your attention the value of warm ether vapour in the prevention of pulmonary complications.

May I add further that I believe that the combination of gas and oxygen with local anæsthesia is the very best anæsthetic agent for a number of the abdominal operations of civil life and for many others also, for it causes no fall of blood pressure, it eliminates anæsthetic shock, and it abolishes post-anæsthetic vomiting and all its attendant troubles. It must, however, be remembered that it is not always a satisfactory anæsthetic for vigorous and muscular people on whom a prolonged operation is to be done, and that its lengthy administration requires both experience and special apparatus.

THE TREATMENT OF PATIENTS WITH FRACTURES.

Let me ask you now to direct your attention for a few minutes to the treatment of fractures, for I think it is the opinion of all surgeons that here there have been great developments. For example, compound fractures of the femur are now treated infinitely better than before the war.

I will briefly sum up the position by saying that the fractures in France in the last half of the war were treated by "extension and suspension," so that the circulation, nourishment, and mobility of the injured limb were maintained throughout as far as possible. Constriction by bandages has been reduced to a minimum, and limbs are no longer encased in wooden boxes or in plaster-of-Paris, and, as a result of the precautions to maintain in this way the vitality of the limb, wasting of muscles and stiffness of joints have been largely prevented.

It is greatly to be hoped that our war experiences will be utilised at home, and that all hospitals and medical schools will arrange for a much more systematic teaching of how to deal with fractured limbs, so that all young surgeons will in future realise that the so-called "setting" of the fracture should be really only the beginning and not the end of surgical treatment. And if this aim is to be achieved it will be necessary that some at least of the fracture cases in general hospitals shall be collected in "special fracture wards" equipped with the necessary apparatus for "extension and suspension," and supplied also with a mobile X ray outfit, for there are many cases where a good result can only be obtained by frequent radiography at the bedside.

Let it be fully realised that so long as the principles I have sketched are kept in view the details of how best to carry them into practice must be left to the skill and ingenuity of individual surgeons.

WOUND INFECTIONS AND ANTISEPTICS.

Throughout the war experience of wound infection was on a larger scale than had been anticipated, and I will only touch on one or two of the more obvious features of this great subject. It is already widely known that tetanus was prevented by prophylactic injections so successfully that its incidence immediately fell 90 per cent, as soon as the anti-toxin could be supplied in sufficient quantities, but it must be appreciated that if success is to be obtained in civil practice the injections should be given within a few hours of injury. Unfortunately we had no similar success in the employment of prophylactic injections for "gas gangrene," and even at the end of the war the most recently manufactured sera were of doubtful value. At first we found no real remedy. Time and experience alone led us to the proper treatment by excision of all devitalised tissue and the careful and thorough mechanical cleansing of the wound; and it was during this period of learning and experimenting that "antiseptics" were given so thorough a trial and were proved to be so valueless when placed in grossly contaminated tissues.

The uselessness of attempting to sterilise a grossly infected wound by the single application of a powerful chemical agent is really nothing new, and my friend Sir George Makins pointed out in his Hunterian oration that Lister himself was quite aware of this, for he wrote, "If for example a pair of forceps is handed to the operator with the intervals between the teeth occupied by dry septic pus, and a portion of this dirt becomes detached and left in the wound, the evil cannot be corrected by any antiseptic wash that is now at our disposal or that the world is ever likely to see." Very striking words! In spite of this dictum, however, some of Lister's admirers in England urged us in France to try to sterilise wounds by the early introduction of powerful antiseptic agents, and with the natural result that such measures were tried and absolutely failed.

Suture of wounds.—I have already said that the only real method of sterilising the wounds of war, as we saw them in France, was by a suitable operation and the mechanical removal of all that might do harm, so that no tissue which is too badly damaged is left. The next question we had to decide was how to treat such a wound subsequently, and, as you are well aware, the answer was ultimately found in the closure of the wound by either "primary" or "delayed primary suture."

And we also learnt both that the results of suture were not materially influenced by the use of any antiseptic agent, and also that wounds could heal well and firmly even though they contained considerable numbers of micro-organisms, so long as the latter did not include virulent streptococci.

It was evident that the tissue cells could destroy the less virulent bacteria, provided that the latter were surrounded by healthy living tissues, and that by closure of the wound the advent of fresh infection was effectually prevented. The presence of bacteria of very various kinds in wounds which nevertheless did well was recorded by observers of every nationality, and especially in the United States units by Crile, Kenneth Taylor, and H. Cabot; and in the British units by Forbes Fraser, Adrian Stokes, McNee, and the workers in Almroth Wright's laboratory. In almost all regions of the body we closed wounds successfully, either by primary or secondary suture; in the head and neck, the limbs, the chest, the abdomen, and the large joints, and we soon learnt by experience that if patients could not be retained at the front after suffering from extensive wounds it was better to send them to the general hospitals with a packing of gauze, and let the wound be sutured without further interference after arrival. We found no advantage in using antiseptic substances with this packing, although many surgeons did employ flavine or solutions of the bismuth, iodoform, and paraffin paste suggested by Rutherford Morison.

Much more might well be said as to details of treatment in different regions of the body, but the results obtained in the later stages of the war may be briefly summed up saying that not only were many lives and limbs saved by wound closure, but that compound fractures healed more rapidly and with much less necrosis, joints were saved from acute arthritis, suppuration of wounds became rare, septic infection with its fever and emaciation diminished, and convalescence was infinitely more rapid. From the army point of view fewer beds were occupied, nurses and surgeons were spared much unnecessary work, and many soldiers were returned to their units fit and well within a few weeks instead of suffering for months from suppuration.

WAR METHODS IN CIVIL PRACTICE.

Surely it is evident that much of what we have learnt is applicable to civil practice. Is it not certain that we shall close open wounds of the knee, that drainage-tubes will be much less employed, and that "delayed primary suture" will become a common method for the treatment of bad compound fractures and the lacerated wounds caused by machine accidents? The same method of wound closure by delayed suture will be found just as useful in amputations through tissues near to suppurating areas. We found it most helpful in the treatment of Syme's amputation, and Colonel Elder, when consulting surgeon at Rouen, showed me a very striking series of successful amputations by Syme's method performed upon natives of India for gangrene following frost-bite, and treated by suture after being packed with gauze for three or four days. I believe that there is a wide field for the application of war methods to the treatment of the injuries of civil life, but I would emphasise that in suturing wounds after the interval of a day or two it is essential for success that no further wound toilet is permissible. The packing should merely be removed as gently as possible and the sutures inserted and tied.

Secondary infections of wounds.—Our experiences of the value of closure of wounds very naturally directed our attention to the question—How did the wounds become infected by pyogenic organisms? We found that not more than 15 per cent. of recent wounds were infected by hæmolytic streptococci when examined in the operating theatres of the casualty clearing stations at the front; but we were told by our bacteriologists at the different bases that within a week of arrival over 90 per cent. were infected; and shortly before the war ended we appointed an Anglo-American Committee to investigate the whole question of streptococcal infection. Of course, it was evident that when wounded were numbered by the thousand it was not possible to ensure complete sterilisation of hands and instruments after each case had been examined or dressed, but it did appear to be very clear that, as instruments are more easily sterilised than hands, it was very desirable not to touch the wound or the dressings except with instruments, for we had no doubt that wounds usually became contaminated when they were dressed. It was then decided that an investigation should be made in order to ascertain whether many of the medical officers, nurses, or orderlies at the bases were acting as "carriers," and 8000 examinations were made (in the American Army) of their throats, with the result that it was reported at the last meeting of the Committee that "carriers" of hæmolytic streptococci had been found in different bases to number from 15 to 25 per cent. of all the hospital personnel. Here, unfortunately, the matter had to be left, for the war had ended, and the streams of wounded men had, happily, ceased to flow.

It is, of course, not to be supposed that carriers of streptococci are to be found in civil life in any such numbers as those I have mentioned; but experience of the general hospitals in France does show the danger of wound infection spreading when large numbers of streptococcal-infected wounds are accumulated in war conditions; and, what is most important, it explains why it was that the closure of wounds by suture was of such great benefit to the wounded soldier. I would also suggest that the investigations we began are worth pursuing in hospital wards given over to the treatment of cellulitis and erysipelas, and that, in the interests of both staffs and patients, this should be done.

Suppurating wounds.—There remains the question of the treatment of suppurating wounds, and here we have learnt two things: first, that it is more often possible to suture them than we had previously thought; and, second, that Carrel's method is often a very great improvement on the drainage-tube and the daily syringing.

With regard to the first, we found in France that very many wounds could be successfully sutured even if they were suppurating. Secondly, with regard to Carrel's method of treating suppurating wounds, there is no doubt at all that it has marked a very great advance. It supplies a thoroughly scientific and carefully thought out technique, and has been proved to be of the utmost value in the hands of many of the best French and Belgian surgeons, as well as in British hospitals. I have seen admirable results from its careful employment, and I believe that where surgeons have had an unsatisfactory experience this has been largely due to an imperfect technique, for in many hands it has given admirable results in stopping sepsis and suppuration, and in enabling granulating wounds to be closed by secondary suture.

It is difficult to decide the rather academic question as to whether the method owes its success to the hyperchlorous solution of Carrel and Dakin or to the method of irrigation, but I think myself that the method is more important than the particular solution. Here, again, we have learnt much that is useful in the treatment of the suppurations of civil surgery, for Carrel's method is not only valuable in the wounds of war, it is quite as efficacious in the treatment of an empyema or pelvic suppuration. I have seen most excellent results from its use in large appendix abscesses on the one hand, or in suppurating joints on the other, and I am convinced that it has supplied to the operating surgeon a valuable addition to his armament.

CONCLUSION.

In conclusion, I cannot doubt that in the future the civilian surgeon will also work even more with the bacteriologist than he did before the war, for it has been by collaboration and experiment that many of our advances have been maintained without risk to our patients. And, whatever we may have learnt, there is inevitably much more to learn in the near future. Let us all keep this in mind, and let us also remember that, as far as details are concerned, a too rigid standardisation may be harmful. The only safe attitude is that we should be always inclined to believe that however good a method may be it is always possible to evolve another which may be better still.

I have endeavoured to point out to you in what I have said that the surgery of the immediate future may well be expected to benefit from our recent experiences; that we should improve our transport service and our first-aid for the wounded in civil life; that shock can be better treated and can often be prevented; that anæsthesia can be rendered safer; that no antiseptic can at once sterilise infected wounds; that in delayed suture we have an important advance in surgical technique, and that suppurating wounds can be treated by improved methods. You are all well aware that were I able to consider in detail the surgery of the various regions, such as the head, the chest, the abdomen, &c., I should be able to record very many examples of advances in surgery, but this is not the occasion for such a discussion, and I am content to deal only with more general principles.

Bradshaw Lecture

ON

THE SURGERY OF THE HEART.

Delivered before the Royal College of Surgeons of England on Dec. 11th, 1919,

BY SIR CHARLES BALLANCE, K.C.M.G., C.B., M.V.O., M.S. LOND., F.R.C.S. ENG.,

CONSULTING SURGEON TO ST. THOMAS'S HOSPITAL, ETC.

(Concluded from p. 79.)

PART III.

INFECTION THE CRUCIAL FACTOR IN HEART WOUNDS.

SEPTIC pericarditis and septic pleurisy are the two most fatal complications of heart wounds. Here, as elsewhere, fulminating infections are met with in which surgery is at present powerless to arrest a fatal termination. Apart from these the most urgent question is, What treatment should be carried out? How can the cavity of the pericardium be efficiently drained, or should it be closed without drainage?

In the peritoneum experience has shown that the most extensive drainage is ineffective and harmful, and that the copious irrigations formerly carried it tend to spread rather than check the disease. urther, that the peritoneum can deal with a rtain amount of infective material when once e source of sepsis is removed, and that drainage no longer always necessary. In the pleura the me holds true, and the removal of a metal fragent and the complete cleansing of the cavity with uze may be followed by suture of the wound and e daily aspiration of any fluid that accumulates ll a cure is effected. The pericardium differs from e pleura and peritoneum in that it cannot be mpletely inspected and cleansed even if the apex nd ventricles are pulled forward so as to expose e mouth of the oblique sinus.

We may take it that the pericardium is widely pen in front right down to the level of the iaphragm; that the patient is reclining in the upine position, with the chest and head well propped p with pillows; and, further, that he cannot lie on is face or on either side, for these positions cause istress, pain, and dyspnœa. This position—the emi-Fowler position—seems perfect for allowing e fluid collecting on the diaphragmatic surface of e sac to flow out and not remain for any time ithin it. From a close study of the case I operated n, Dr. White and I were early convinced that we ad not succeeded in a satisfactory surgical manner draining the pericardium of our patient.

THE DRAINAGE OF THE SINUS BEHIND THE LEFT AURICLE.

The subject of the surgery of the heart has been o extensively reviewed in numerous papers of reat merit, that as I became acquainted with the terature of the subject I began to doubt whether here was anything new for me to contribute to the iscussion of this important topic. Let me mention s examples three papers. Sir John Bland-Sutton[1] ontributed a paper on "The Treatment of Injuries f the Heart" in 1910. Sir William Thorburn[2] in he same year published a paper on "Cardiolysis," nd in 1909 appeared Matas's[3] (New Orleans) dmirable essay on "The Surgery of the Heart." I ropose, therefore, to confine myself to pointing out practical detail in the treatment of suppurative ericarditis—namely, the drainage of the sinus or ursa behind the left auricle.

Anatomy.

The pericardium is conical in shape, attached by ts base to the diaphragm, while the upper and arrower part surrounds the great vessels. It is upported in front by the ligaments of Luschka, ehind by the ligaments of Béraud, and below by he phreno-pericardial ligaments. From base to ummit it measures from 12 to 14 cm. The ibrous layer is a dense, unyielding, fibrous membrane. The serous membrane has a visceral nd parietal layer; both are in close contact in ealth, and only sufficient fluid is present to acilitate movement. The sudden effusion of "200 o 250 g. (7 to 10 oz.) of liquid, as in hæmorrhage into he pericardium, is sufficient to arrest the heart's ction by compression, while in chronic distension he fibrous layer will gradually give way and 500 to 2000 g. (17 to 60 oz.) of fluid may collect in the sac without causing death."[4]

The reflections of the serous membrane on to the great vessels cause the formation of pouches or recesses. The most important recess, and the one which I want to direct your most particular attention to, is situated behind the left auricle. It is described by French anatomists as the cul-de-sac of Haller, in English works as the oblique sinus, and by Professor Keith as the bursa of the left auricle. It extends upwards between the right and left pulmonary veins and arteries to the upper border of the left auricle. It is 4 to 5 cm. in depth and behind it is the œsophagus. The vestigial fold of the pericardium forms a small pouch which leads into the oblique sinus. The vestigial fold is a doubling of the serous membrane between the left pulmonary artery and vein and contains the remains of the left superior cava. This smaller pouch or diverticulum of the oblique sinus is also behind the left auricle. The large pouch[5] (bursa of Keith) is blind at its upper extremity; it extends obliquely upwards and towards the right as far as the superior cava. The lower end is widely open below at the level of the groove on the posterior surface of the heart between the left auricle and ventricle. The right border of the opening is on a lower level than the left and reaches down as far as the inferior vena cava. The opening therefore faces downwards, forwards, and towards the left. The lateral borders or surfaces of the pericardium are in contact with the lungs, are in constant movement, and are not much under tension. When fluid collects in the pericardium it accumulates mainly in the two postero-lateral pouches of the pericardium on each side of the middle partition formed by the projection of the superior and inferior cavæ and right auricle; and in the dome-shaped space above. The heart cannot move backwards, but its apex and ventricles are crowded forward by the fluid which has accumulated in the postero-lateral pouches, always approaching the chest wall more closely as the tension of the pent-up fluid increases. I made this observation in my case when the pericardium was freely opened and the fluid quickly escaped; the apex of the heart sank down and shut off from the rest of the cavity the recess behind the left auricle; and the failure to drain this recess properly was, I believe, a cardinal factor in the fatal termination of the case. We have to picture to ourselves not a distended pericardium but a cavity freely opened in front, with the cul-de-sac of Haller undrained because the position of the heart blocks the exit of fluid from it. I studied this problem in my patient day and night for three and a half weeks, and its solution is, I believe, of vital importance in the treatment of septic pericarditis.

I distended the pericardium of a young adult cadaver with about 7 oz. of liquid gelatin, the thorax being in the erect position. When the gelatin had set, the apex of the heart was separated only by 3 mm. of gelatin from the front of the distended pericardium, while the base was covered with gelatin 2 cm. (¾ m.) thick. In a distended pericardium the apex of the heart is carried forwards, and the contents of the oblique sinus can escape, but with the emptying of the pericardium the ventricles and apex drop backwards and shut off the oblique sinus from the rest of the pericardial cavity. I made an incision in the left lateral wall of the distended pericardium opposite the mouth of the oblique sinus, and passed

[5] In a formalined prepared body in which the left auricle was contracted, the pouch of Haller held more than 1 oz. of water. Under normal living circumstances the pouch of Haller is only a potential space (see Braune's plates).

a large blunt-ended metal probe through it and through the gelatin in the oblique sinus as far as it would go with gentle pressure. The probe disappeared for 4¾ in.

Illustrative Cases.

The two cases following offer a striking contrast: (1) Delbet's case, which ran an aseptic course; (2) my case, which is a typical example of acute suppuration within the pericardium.

Removal of bullet wound from heart; recovery. Paul Delbet's case (1917).[6]—An infantryman, aged 31 years, was wounded on April 16th, 1917, near Craonne, by grenade splinters in the right side of the thorax posteriorly, also in the right arm and forearm. He became confused, and then lost consciousness for about 20 minutes. From the dressing station he was sent to the nearest field hospital, where he remained several days. The wounds in the upper limb were treated, and fragments of clothing were removed from the wound in the thorax. The case was not considered grave, and no X ray examination was made at that time. He reached Paris on May 2nd. His face was then wax-coloured, respiration was frequent and shallow, and the slightest exertion caused dyspnœa. Temperature 104°F., pulse 120. Behind and to the right, three finger's breadth from the median line, was a suppurating wound 3 cm. long, where a grenade fragment had entered; there was no wound of exit. There was congestion of lower lobe of lung on both sides and the area of cardiac dullness was considerably increased. Radiography showed a foreign body within the heart shadow, a little to the right of the median line 6½ cm. from the level of the sixth costal cartilage. By the stereoscopic method it was shown to be in the right side of the heart.

Operation (June 26th) 70 days after the injury. An osteoplastic flap with base outwards (Delorme's method) was turned back. The mediastinal fat and cellular tissue were displaced; in doing this a small opening in the pleura was made and was closed with forceps. The pericardium was picked up with forceps and incised; it was closely adherent all over. The adhesions were separated with the finger, first on the left and then on the right side. A foreign body was felt in the middle of the right ventricle. The heart could not be held in the gloved hand, from which it slipped like a live fish; glove removed and heart seized with the left hand and rotated a little towards the right; an incision 3 cm. long was made in the right ventricle, the foreign body seized with forceps and removed. The wound in the ventricle was closed with three No. 2 catgut sutures. Pericardium and external wound sutured. The foreign body was a fragment of steel, irregularly cubical in shape, 1½ cm. in diameter.

The patient was well in 12 days, and was shown in Paris in September, 1917, in good health.

Removal of a rifle bullet from the right ventricle of the heart[7] *by White and Ballance.*—Trooper M., aged 21, was wounded by a bullet on Nov. 14th, 1917. He rode some miles to the nearest dressing station and then collapsed. On examination it was found that the bullet had passed through the upper part of the right arm behind the humerus, and then entered the right chest between the fourth and fifth ribs and had not emerged. A radiogram taken the next day showed the bullet 2 in. from the surface in the cardiac region on a level with the inferior border of the heart; the bullet moved with the cardiac pulsations. It was thought to be in the wall of the left ventricle near the anterior margin. There was some fluid at the base of the right pleura. Patient admitted to St. Elmo Hospital, Malta, from Salonika on Jan. 13th, 1918, as a cot case.

On admission general condition good. While lying down pulse 96, steady and regular; on exertion, such as getting out of bed or picking up an object off the floor from the bed, the pulse became irregular and rapid. He was once allowed to cross the ward, when the pulse rose to 130 and the face became pale. The other clinical findings were all negative, except for a small goitre, which had been present for years. The patient came from Derbyshire. Repeated X ray examinations, both with the screen and by means of stereoscopic plates, were made. These showed movement of diaphragm independent of the bullet. The bullet lay behind the left fifth cartilage and left fifth intercostal space ¾ in. from the left border of the sternum and about 2 in. deep from the skin surface in front. The base of the bullet lay towards the right, while the pointed end was directed towards the left and somewhat downwards, and moved more than the base with the pulsations of the heart. It was thought that the base of the bullet was fixed in the wall of the right ventricle, and that the pointed end was in the cavity of the right ventricle.

The patient had suffered severely from sea-sickness during the voyage from Salonika, and this had caused much distress from palpitation and choking sensations. Further, the rapidity and irregularity of the heart on the slightest exertion and the known position of the bullet made it desirable to perform an exploratory operation in order to determine whether it was possible to remove the bullet. The patient had remained in bed under observation without improvement.

Operation (Feb. 16th, 1918).—The Delorme-Kocher incision for exposure of the heart was made and the fourth, fifth, and sixth costal cartilages of the left side were removed. The internal mammary artery was tied in two places and divided between the ligatures. The triangularis sterni was divided, and the border of the left pleura, crossing obliquely the front of the pericardium, was seen and thereafter held aside. No injury to the pleura occurred. The anterior surface of the pericardium appeared normal except for a small, puckered scar half an inch from the left border of the sternum about the level of the fourth space. An incision was made in the pericardium passing obliquely downwards and towards the left, and as long as the resection of the chest wall allowed. A very little gas and frothy fluid escaped, but no adhesions between the parietal and visceral layer of the pericardium were found. The anterior surface of the heart appeared normal both to sight and touch. One of us (W.) then palpated the posterior surface of the heart and at once felt the bullet through the wall of the right ventricle near the apex. Fixation stitches of No. 1 silk were then passed close to the apex of the heart along the anterior interventricular groove. These threads were used to pull the apex of the heart forwards and upwards; a first-rate exposure of the posterior surface was thus obtained. On the posterior aspect of the heart no scar was visible and no bulging was seen. Palpation determined that the bullet was lying near the apex of the heart on the right side of the posterior inter-ventricular groove, and was apparently in the ventricle. Four silk stitches were next inserted in the wall of the right ventricle along the line of the proposed incision; they passed twice through the muscle, so that the loop could be drawn out of the way while the incision was being made. One of us (B.) then seized the heart with the left hand, using the thumb to compress the right ventricle above the line of the proposed incision. It was found difficult to cut the quickly contracting heart muscle with the knife, so the incision into the ventricle was completed with scissors. B. then introduced a pair of artery forceps into the cavity of the right ventricle through the incision, seized the free extremity of the bullet and pulled it outside the heart. In doing so the inner surface of the ventricular wall was everted, exposing the columnæ carneæ, because the base of the bullet was firmly embedded and attached to this surface. W. then, with a knife, cut the inner aspect of the ventricular wall and the bullet was free. The hæmorrhage was fairly profuse, but was at once controlled by pulling on the stitches which had already been passed, and by putting in four more, so as to invert, Lembert-like, the outer wall of the ventricle. The manipulation at no time affected the work of the heart, and the pulse only failed momentarily when blood was escaping from the heart. There was no visible sign of inflammation or sepsis. Some saline solution was left in the pericardium and the incision stitched up. The superficial incision was also closed and the patient returned to bed without shock. Colour good, respiration 20, pulse 110. Throughout the operation the blood pressure was carefully noted. The subsequent history after the first few days was that of progressive sepsis, with free discharge from the wound, and although the patient was carefully tended he died on March 14th.

[7] Journal of the R.A.M.C., December, 1918.

Autopsy.—Wide gaping wound in præcordial region; large opening in pericardium; considerable area of anterior aspect of heart exposed. Petechial hæmorrhages subcutaneously and over some of the viscera. The thoracic viscera were taken away entire and preserved in 10 per cent. formalin for further examination. After fixation, both lungs normal. No enlarged glands in hilum of either lung or in mediastinum; the latter was normal. Œsophagus, trachea, and main bronchi normal. The right lobe of the thyroid extended downwards to the bifurcation of the trachea. This enlargement and extension downwards of the right lobe of the thyroid pressed the trachea towards the left, giving it a definite curve in that direction. At the back of the right lobe of the thyroid was a cyst 1½ in. in diameter containing pus; below the cyst was more thyroid tissue. The thoracic lobe was 2½ in. long by 1½ in. wide and was circular on horizontal section. On section numerous cysts were seen, many of which contained pus. In part the interstitial tissue contained calcareous matter. The pericardium was opened from behind. It was lined by a thick adventitious membrane; the visceral layer was everywhere intact but thickened, and some petechial hæmorrhages were seen. The line of incision at the back of the right ventricle was not visible, but two or three puckers on the surface of the heart gave some indication of the site of operation. The operation incision had healed. Microscopic sections through the site of incision in the ventricular wall showed the line of incision occupied by young connective tissue and evidence of pus at the surface; other sections showed encapsulation of ligature and changes in the cardiac muscle near the incision.

Remarks.

While the operation was carried out in many respects on the ordinary principles of surgery, treating the heart muscle like any other tissue of the body, the after-treatment was not in its early stages so conducted. When the patient became ill, instead of treating the case on ordinary principles and opening the lines of incision, we were absorbed in dreams and idle speculations, one of which was that clot was forming on the wound in the interior of the right ventricle, and that its extension was embarrassing the action of the heart. It is a common experience that bullets frequently lodge in the tissue and induce neither local nor general infection until attempts at removal are made. The total absence of adhesions or any visible sign of inflammation in the pericardium and heart led us to close the wound in the pericardium, which was a fatal mistake. Further, on opening the pericardium, we had observed a little gas and frothy fluid which, notwithstanding all the other appearances, must have been pathological, so that looking back we may affirm that there was no valid excuse for closing the pericardium. As a matter of fact, the pericardium and superficial wound should have been left widely open as if the operation had been done for suppurative pericarditis. The question of possible sepsis was ignored, and, further, in order not to leave any air in the pericardium, which might have caused surgical emphysema, normal saline solution was left within it, and we believe that this must have embarrassed the heart and promoted sepsis.

In the course of the case it appeared reasonable to assume that an abscess might form in the posterior mediastinum. We found by experiment on a cadaver that the removal of about 2 in. of the sixth and seventh ribs commencing 2 in. from the spines of the vertebræ enabled us to reflect the parietal pleura without injury or difficulty and to enter the mediastinum. In this subject the posterior surface of the undistended pericardium was 5 in. from the skin surface of the back.

Before operation we obtained bullets of different nations to see whether a magnet would be useful in removing the bullet from the patient. It was probable, indeed certain, that the bullet lodged in the patient was projected from a Bulgarian rifle, as the only prisoners taken in the action in which this soldier was wounded were Bulgarians. The modern Bulgarian bullet tested by us was not magnetic, while the modern Serbian bullet proved strongly magnetic. We therefore did not have in the theatre the powerful electro-magnet made for us by the Royal Engineers. After removal the bullet proved to be an old Bulgarian bullet and was strongly magnetic.

It was impossible to drain the pericardium by placing the patient in the prone position, as the heart then immediately blocked the exit from that cavity; besides, the distress of the patient was insupportable. At one time we thought that an abscess was forming in the posterior mediastinum because of intermittent discharge of pus from the left side of the posterior part of the cavity; this portion being inaccessible to visual examination, we could not judge what was going on there, as we could in all other regions of the pericardium. Indeed, we almost hoped that an empyema would form in the left pleura, because then it would have been possible to drain the empyema, and at the same time to make an incision in the pericardium far back on the left side. We were familiar with a case of suppurative pericarditis, complicated with left empyema, in which this operation was done, and the patient recovered.[8] But in this heart case no empyema occurred and no extension to the mediastinum; indeed, the thick strong wall of the pericardium could not easily or quickly give way to softening or perforation by the action of pus not under pressure. The local treatment consisted in discontinuous or continuous irrigation with normal saline solution or eusol. When a jug of fluid was slowly poured into the pericardium the sac would soon appear quite clean, the pus having been washed away. It was constantly found, however, that pus kept welling up from the region behind the left side of the heart either continuously or in gushes. The phenomenon was constant, and it was certain that it came from a cavity or pouch in the left postero-inferior region of the pericardium, or from a cavity outside the pericardium which intermittently discharged its contents into the pericardium. We felt that for successful treatment this pouch must be drained by incision of the posterior or left lateral wall of the pericardium. The use of a small red rubber catheter pushed from the right side behind the heart (as we thought into the pocket) did very little or nothing to control these gushes of pus. The tube was kept in place for days behind the heart and continuous and discontinuous irrigation was employed; no disturbance of the heart's action was produced.

The examination of the pericardial pus showed the presence of *Streptococcus pyogenes*, *Staphylococcus aureus*, and a long thin bacillus, which was gas-producing and which Major Russell could not identify. In the effort to check the sepsis we resorted to intravenous injections of perchloride of mercury solution and also to transfusion of blood.

---

[8] See also case by Steward and Garrod, R. Soc. of Med., 1907.

The patient became very anæmic towards the end. The red blood count was only 1,500,000. Bazett's apparatus was used for transfusion. The blood was allowed to flow for 5½ minutes; the operation was continued till the blood pressure of the donor fell to 90. Next day Major Russell estimated that 2 out of every 3 red corpuscles in the patient's blood had come from the donor.

SOME FURTHER REMARKS ON THE OPERATION AND THE PROPOSAL TO DRAIN THE CUL-DE-SAC OF HALLER.

A. In an urgent case the surgeon must operate without being certain of the diagnosis. The operation is done to obviate impending death, and all else is secondary. There will be the wound, the signs of hæmorrhage, and the increase in præcordial dullness; but whether the general state of the patient is due to a wound of the heart, or of one of the great vessels, or of the root of the lung, or of the internal mammary, or the intercostal artery cannot be determined before operation. In my case I had the opportunity of observing the effect produced by the filling of the pericardium with fluid under tension. "Then breathing became laboured and shallow, the extremities cold, there was free perspiration, great thirst, and much pain in the left side of the chest. During the night the patient was very restless, the face and limbs cyanotic, and the pulse very feeble." When fluid finds no outlet from the pericardium as illustrated in this case the "Herz-tamponade" begins, and is indicated by the signs of venous retardation caused by compression of the auricles. During a coughing fit on the following morning a large quantity of clear fluid escaped from the pericardium. The patient collapsed and became unconscious and pulseless. He revived in half an hour under the vigorous use of restoratives, then asked for his breakfast; pulse strong, 90, breathing deep and easy, all pain gone. After breakfast he slept quietly for three hours, and on waking up expressed himself as being well; the blood pressure was 120.

Signs and symptoms.—In purulent pericarditis the upper segments of both recti may be rigid, and there may be a narrow band of œdema round the front and left side of the trunk about the level of the fifth interspace. I have seen this band of œdema and I have known suppurative pericarditis mistaken for inflammation below the diaphragm. Absence of diaphragmatic movement is indicative of pus in contact with the diaphragm.[9] In pericarditis with effusion the right lobe of the liver is low; in dilatation of the heart the right lobe of the liver is not depressed.[10] Moog reports a case in which he tapped a much-distended pericardium through the fifth space in front and through the eighth space behind. This is important, for Mackenzie reports having tapped a purulent pericardial effusion from the back in mistake for an empyema.[11] Many observers have found a small area of dullness in the left back just inside the angle of the scapula. This was discovered by Sir A. Garrod in my case, and being associated with slight difficulty in swallowing was thought at first to indicate a collection of pus in the posterior mediastinum. The early diagnosis of purulent pericarditis is greatly assisted by X ray examination and by the blood count record. These should never be omitted.

B. Contrary to Delbet's experience, I found no difficulty in holding the heart with the gloved hand; the heart was said to wriggle out of Delbet's gloved hand like a live fish. My success in holding the heart was, I believe, due to the fact that the apex was drawn forward by fixation stitches, which assisted to control all movements except the pulsations. In any future operation on the heart I should certainly place a fixation stitch or stitches through the apex as a preliminary measure.

In suturing a wound of the heart fine vaselined silk and small round needles should be employed No salt solution should be left in the pericardia sac; it should be gently dried with gauze. In profuse suppurative pericarditis the edges of the pericardial wound should be stitched to the skin.

In young children as a complication of pneumonia or empyema suppurative pericarditis is not uncommon, and with the pericarditis there is sometimes a septic gelatinous-spreading mediastinitis In children especially I think it is advisable to stitch the opening in the pericardium to the skin in the hope that mediastinitis will be prevented Every case of suppurative pericarditis which is no drained must end fatally. There are strong advocates for and against pericardial drainage. I refer particularly to cases of gunshot wound of the heart or pericardium. It would seem that in many such cases drainage is a mistake. Statistics do no really help—e.g., one writer quotes the following:—

Pericardium and pleura closed in 30 cases; 2 recovered.

Pericardium and pleura drained in 43 cases; 2 recovered.

These figures are not of decisive significance, fo each case must be decided as far as drainage i concerned on its own merits. No two cases ar alike. It is from the study of individual cases tha the right treatment will be evolved.

C. *Drainage of the cul-de-sac of Haller.*—Certai cases of suppurative pericarditis recover wit simple drainage through the anterior wound; ther are others that do not, and it is in these tha drainage of the cul-de-sac of Haller must be con sidered. The tube cannot be introduced into thi pouch by passing it under the heart from the lef side; it might, indeed, not even lie in the mouth c the sac, but remain between the heart and th diaphragm. The same thing is true of any attemp to introduce a tube into the pouch by passing i between the left border of the heart and the inne surface of the left lateral wall of the pericardiun because these are in close apposition and drainag would probably be no better than if the tube wer carried under the heart, and, further, because th operator would be directing the tube backward while the long axis of the pouch is in the vertica direction.

---

[9] Porter (Annals of Surgery, 1900, p. 769) analysed a large number of cases of suppurative pericarditis. The operation mortality was 60 per cent. The amount of pus evacuated varied from 10 oz. to 2 quarts. Rhodes (Annals of Surgery, 1915, p. 660), in a paper on Suppurative Pericarditis, adds 13 cases to those of Roberts, 1897 (35 cases); Porter, 1900 (16 cases); and Eliot, 1909 (22 cases); making a total of 86 cases. He voices the opinion that aspiration is dangerous and that X-ray examination and the blood count are of great value. Davis (Surgical Clinics of Chicago, 1917, p. 375) relates a successful case of suppurative pericarditis treated by operation. He refers to Février's 9 cases treated by aspiration, all of which were fatal. (Contrib. à la Chir. du pericarde and paracentèse et pericardiotomie, Bull. gén. de Thérap., 1889, cxvi.) He says the mortality of incision is 45 to 50 per cent.; and that the position of the right border of the left pleura is so variable that no accurate idea of its relation to the pericardium is possible.

[10] Calvert: Jour. Amer. Med. Assoc., 1910.

[11] See paper by Robey, Amer. Jour. Med. Sci., April, 1917.

In my opinion, the only satisfactory way of draining the pouch of Haller is by making an opening in the left lateral wall of the pericardium opposite the mouth of the pouch. In order to do this there are obvious advantages in the adoption of the Spangaro operation.

In most cases the tube will lie inside the pleura in its course to the surface and should be packed round with gauze, but if the pleura and lung are not wounded it might be possible to strip back the pleura and push back the lung from the lateral boundary of the pericardium, making the incision in the proper place in the pericardium without opening the pleura.

In reading the records of cases of suppurative pericarditis one is struck with the almost universal difficulty experienced in maintaining drainage. Take, for example, the case of Hilsmann[12] that recovered. A free incision into the pericardium was made in the fourth space. Two pints of pus came out, and much more escaped during the next few hours. During the after-treatment the patient had to bend over, so that his chest was in the position it would have been if he had been standing on his head, in order to empty the pericardium. This manœuvre would cause the ventricles to move forward, and thus the mouth of the cul-de-sac of Haller would be opened.

Again, a fatal case[13] is recorded in which, though a half-pint of thin greenish pus was evacuated through an anterior pericardiotomy, yet at the post-mortem an abscess cavity was found behind and to the left of the heart within the pericardium.

Lastly, cases of purulent pericarditis with left empyema, in which the pericardial wall has been incised through the empyema opening, seem to have a better chance of recovery than those drained through an anterior pericardiotomy. The presence of pus pent up in the cul-de-sac of Haller, quite independently of the effect of sepsis, must interfere seriously with the function of the left auricle.

CONCLUSION.

I am well aware that the suggestion I have made that in certain cases of purulent infection of the pericardium the cul-de-sac of Haller should be drained is not founded on the actual successful performance of the operation, but I venture to maintain that such an operation is justified on the anatomical and pathological considerations which I have endeavoured to set before you.

I do not doubt that the surgery of the heart will occupy in the coming time a conspicuous place in surgical practice. The reward of success will attend our efforts in so far as the heart is treated as one of the ordinary tissues of the body and the method of operation conforms to the fundamental principles of surgery.

What developments in this field of surgery may take place we cannot know. It is best to be content with the present splendour and not to be impatient to paint yet more glorious triumphs on the cloud curtain of the future.

---

[12] Ueber die Paracentese des Pericardiums, Kiel, 1875, Inaug. Dissert. This is one of the 51 cases described by Porter in the Annals of Surgery, 1900.

[13] Coutts and Rowlands: Brit. Med. Jour., Jan. 2nd, 1904. Pericardium exposed by removing the left fifth cartilage and nibbling away a bit of the adjoining cartilaginous sternum. Half a pint of thin greenish pus escaped on incising pericardium. Death three months later. Autopsy: Besides other lesions an encapsuled abscess containing 3 oz. of pus was found. The cavity lay behind and to the left of the heart and within the pericardial sac. The original anterior pericardial wound was not quite closed. It led to a small pocket of pus in front of the heart.

TREATMENT OF
MALUNION IN FRACTURES OF THE FEMUR.

BY W. ETHERINGTON WILSON, M.R.C.S. L.R.C.P. LOND.,
MEDICAL OFFICER, I/C FEMUR WARDS, 1ST LONDON GENERAL HOSPITAL.

Introduction by

SIR ANTHONY BOWLBY, K.C.B., K.C.M.G., K.C.V.O., F.R.C.S. ENG.,
TEMP. MAJOR-GENERAL, A.M.S.

SOON after the armistice was signed in November, 1918, British soldiers who had been wounded and taken prisoners to Germany began to arrive at our base hospitals in France. Amongst them were a considerable number of fractures of the femur, many of which I saw and examined. Without exception the condition of all these fractures was so extremely bad that they excited universal comment and condemnation, and caused me to inquire into the method or methods of treatment which they obtained behind the German lines.

I had long been aware that many of the Germans had looked upon a soldier with a fractured thigh as a useless encumbrance and hardly worth treating; as long ago as November, 1914, they had deliberately left such a man to die in Ploegsteert Wood, and on three other separate occasions I had personally known men brought by our soldiers into our "C.C.S.'s" who had been refused removal by German stretcher-bearers, stripped of their tunics and equipment, and left on the ground in their shirts. I had also seen some of our prisoners exchanged two years ago as useless on account of fractures of the thigh with gross deformity and shortening, who were returned to England because German surgeons looked upon them as too bad for any surgeon to cure. Yet a large percentage of them recovered with good limbs after appropriate surgical treatment in England. I was therefore quite prepared to find that the results obtained by German surgeons in general were very bad, and, I must add, that, as far as I could ascertain, their own soldiers and ours were treated by the same methods.

The ignorance of the essential principles of treatment must have been very widely spread if one may judge from the similarity of the results from different parts of Germany.

The following was the routine method:—

When picked up the patient was placed upon a stretcher without any extemporised splint, such as a rifle, and was then transferred to an evacuation hospital 10 to 20 miles to the rear. No attempt was made here to operate under an anæsthetic, and dressings often remained unchanged for several days at a time.

In most of the cases the limb was splinted at this stage, but the only splint usually employed was a trough-shaped wire splint without a foot-piece. I have seen many of these, and they were so frail as to be of little use. As no extension was applied, the limb rolled out with the weight of the foot and shortened to a variable extent.

In this splint the patient remained and was transported farther back. The wounds were generally dressed every second day. After the lapse of about two or three weeks the wire splint was commonly removed and the injured limb was enclosed in plaster-of-Paris, which was taken up over the pelvis as far as the nipples. During these two or three weeks more and more shortening had taken place, and the malposition was now rendered permanent by the plaster case. The wound was still dressed every two or three days through a "window" cut in the splint. After a further period of about two months the plaster case was removed and no other splint treatment was adopted. Sores caused by splint pressure and by vermin were the rule. After this stage had been reached the patient was either left in bed, if too ill to move, or was allowed to get about on crutches. If union of the fracture was materially delayed amputation was frequently resorted to.

Such is a bare outline of the methods adopted in the case of British prisoners who have been restored to our hospitals, and such, I believe, was the routine treatment of German wounded also. No improvement of methods was discoverable even at the end of the war.

I think that perhaps the most remarkable fact is that "extension," which has been the routine method in most countries for over 40 years, was practically never employed, but I should add that at Cologne one "professor" did employ it in the most primitive and barbarous manner in the chief hospital for prisoners in that town. This method was as follows:—

First, an incision was made two inches behind the anterior superior iliac spine, and then the bone was perforated and a steel hook put through the ilium and brought out above the iliac crest. To this hook a cord was attached, and at the other end of the cord two bricks were slung over the head of the bed. Another steel hook was fixed to the tibia below the tubercle, and to this a cord was attached and two other bricks were slung over the foot of the bed. A whole ward of 30 British patients were thus treated in Cologne until the "professor" died and his colleagues abandoned the method. All hook wounds suppurated and were, as a rule, still suppurating when the survivors arrived in France.

How many of the British prisoners with fractured thighs lost their limbs by amputation and how many died we have no means of knowing, but the evidence of the survivors shows that both these results were of frequent occurrence. The whole story is very discreditable as far as the German surgeon is concerned, but, fortunately, the results obtained in England by operations on the shortened and deformed limbs go a long way to make amends.

Treatment of Malunion in Fractures of the Femur.

By W. ETHERINGTON WILSON.

Repatriated prisoners of war from Germany have supplied most of the cases of our series in which osteotomy has been done. Other sources have also produced their quota of crooked thighs. These cases are interesting, for they show the results of the ignorant and vicious methods practised by the German, causing hideous and awful crippling which by present-day methods are avoidable. Major M. Sinclair, in THE LANCET of March 29th, 1919, drew attention to these facts.

The results following osteotomy as done by Mr. Harold Wilson, M.S., F.R.C.S., have been excellent and amply justify the operative technique employed.

The after-treatment of the cases in the femur wards follows the teaching of Major Sinclair, whose inventive and mechanical mind has turned the fractured femur into an interesting study. The treatment of fractures has received an impetus during the war which cannot be lost sight of, and it is hoped that the wage-earning capacity and the standard of efficiency required by a man's work will not be lowered in the future to the extent described in 1908 by Mr. Clinton T. Dent in his annual oration on the "After-effects of Injuries," in connexion with the Metropolitan Police, read before the Medical Society of London.

Actual Conditions Present in Malunion.

(1) *Shortening* from 2 in. to 7 in. caused by overlapping of the fragments and bowing of the union in one or other direction. The pull of the rectus femoris and hamstrings are chiefly responsible.

(2) *Bad alignment.*—This varies according to the site of fracture.

(*a*) *Backward sagging* of the lower fragments with union at an angle directed backwards is a common deformity present in these cases. It is one of the worst deformities of the femur, and one of the most prone to occur, especially in lower third fractures in which this deformity eventually produces genu recurvatum, resulting in disorganisation of the knee-joint and crippling. The chief factor producing this, apart from gravity, is the backward pull of the gastrocnemius.

(*b*) *Outward bowing*, caused either by union at an angle outwards, or by using the limb too early without support in cases of soft or frail union, is common. In some cases of soft union, when all apparatus has been removed, the thigh will bend outwards by muscular action only. When this bowing occurs in lower third fractures the knee-joint is thrown out of line, and an unequal strain on some parts of the joint follows, resulting in crippling. The muscles concerned in the bending of the thigh outwards are those causing abduction of the upper fragment, assisted by muscles attached to the pelvis and the femur, which lie in a vertical plane internal to the bone itself, forming, as it were, the strings of a bow.

(*c*) *Forward or inward bowing* of the femur is not common.

(*d*) *Flexion, abduction, and external rotation* of the upper fragment, particularly in upper third cases, is a common deformity, these three conditions coexisting. The amount of external rotation is judged by the appearance of the lesser trochanter in an antero-posterior skiagram; the greater the external rotation, the more of the trochanter is visible. The unopposed pull of the external rotators, glutei, and ilio-psoas, and the slackening of the strap-like ilio-tibial band all help in the production of this malposition of the upper fragment. The results of inefficient treatment in these cases are shortening, T-shaped union of the fragments, and an unsightly thigh, the end of the upper fragment often making its way through the skin.

(*e*) *Internal rotation of the lower fragment* is caused by the rest of the limb below the fracture being allowed to roll inwards, chiefly through lack of support. Union in such a position results in the toes being turned in to a varying degree, and this, combined with other deformities present, makes progression exceedingly awkward. The result of union of a fracture in which the upper fragment is very much rotated out and the lower rotated inwards, leaves a condition in which the patient has little or no power to turn his toes out voluntarily.

(*f*) *Traumatic coxa vara*, present in some cases of fracture of the neck of the femur, resulting in shortening and adduction. Osteotomy at the site of fracture was not done in these cases owing to the risk of suppuration in the hip-joint.

(3) *Impaired movement of knee-joint.*—The range of possible flexion was very poor in most of the German cases, as, apparently, no attempt was made by them to deal with the knee question. In one case in which good movement was present it was only got at the cost of increased deformity due to the man being allowed to walk very early and without any walking appliance.

Causes of Undue Stiffness of the Knee in Fractured Femurs.

(*a*) Suppuration among the thigh muscles, particularly the quadriceps extensors, resulting in scarring and fixation to the bone. This scarring of the quadriceps, especially when near the knee, is the most important cause of a stiff joint. (*b*) Inflammation and injuries about the joint, in some cases caused by the use of callipers, transfixing pins, &c. (c) Prolonged immobilisation, with no efforts at massage and movement.

Extension through the knee-joint is not of itself responsible for stiff joints. Instructive examples of this fact were seen amongst some of the prisoners of war, of which the following case may be regarded as typical.

Pte. M. had an almost immovable knee-joint before osteotomy. When a knee-flexing splint came to be fitted after 10 weeks' extension in a straight Thomas, 20° of flexion at the knee-joint was found possible.

General Principles in the Treatment of Malunion.

In the cases requiring osteotomy the bone was divided at the site and in the plane of union of the original fracture. The further treatment of these cases was carried out in the femur wards, and the stages may be very briefly mentioned and summarised as follows:—

First position.—Application of a well-fitting Thomas's splint, &c., the thigh being kept in position by an extension, for which purpose Sinclair glue or two screws in the upper third of the tibia were utilised; I prefer the tibial screw extension to any other form and this was chiefly used. Callipers to the knee were not used. The limb is supported by slings clipped in position in the usual way and the foot controlled by Sinclair's foot-piece. Extension is obtained by "body-weight," the amount being regulated by the height of the foot of the bed.

Extension by screws into the tibia. (Fig. 1.)—These were largely used in the cases of osteotomy for mal-union where a heavy pull was required in the first position. Method of application: The leg is shaved in the area of operation and the strictest aseptic precautions are necessary. The patient is anæsthetised.

Inner screw. A horizontal incision ½ in. long is made down to the bone on the inner side mid-way between the anterior and the postero-internal borders of the subcutaneous surface of the tibia, 1 in. below the tubercle. A hole is bored slightly downwards, backwards, and outwards through the compact bone, passing across the medullary cavity, and striking off the compact tissue of the opposite side. The diameter of the boring instrument should be less than that of the screw. The latter is driven home, and it is most important that a firm grip should be obtained into the compact tissue of the opposite side. The screw is 2 in. long.

The outer screw, 2½ in. long, has to pass through the anterior tibio-fibular compartment of the leg before reaching the antero-external surface of the shaft. The skin incision is made in the same way, but at a lower level, so that the screws do not foul each other, and the knife is then carried in a plane at right angles to the original incision so as to do the minimum amount of damage to muscle. The screw is fixed in position in the same way as described above, but it is rather more difficult than in the case of the inner one. About ½ in. or more of each screw remains unburied, and over each of these a metal ring-shaped 8 is applied, one of the loops having 3 ft. of strong tape firmly tied on to it. Dressings soaked in a 5 per cent. solution of picric acid are applied, and the whole field of operation is concealed by a sterile gauze roll. This dressing is never removed unless occasion arises.

The two tapes are tied round a square extension support of metal fixed to the end of the Thomas, the ring of the splint having been pushed up the thigh previously as far as the tuber ischii. The width of the extension support keeps the tapes clear of the malleoli.

Advantages of screws.—(1) They are absolutely painless if properly inserted. Those cases which have experienced both glue and screws infinitely prefer the latter. A patient upon whom osteotomy had been performed was not aware that screw extension was being used until he was questioned about them four weeks later. (2) In certain cases when the skin will not stand a pull by glue, screws will save much trouble both to the patient and the surgeon. (Screws must not be applied to blistered parts.) (3) Once inserted, the screws last throughout the treatment of a case. (4) Unlike the wounds produced by many callipers, they do not cause a zone of inflammation, and the wound heals in a few days when the screw has been removed. (5) A greater amount of pull can be obtained than with glue, sufficing for all practical purposes.

Disadvantages.—(1) The possibility of sepsis, depending entirely on the precautions taken. Our results have been excellent, and nothing untoward has occurred. (2) An anæsthetic is needed for their insertion, but in cases in which the femur is being put up under an anæsthetic or an operation done in the theatre the screws are done at the same sitting.

No anæsthesia is necessary for their extraction; the process is not so painful as pulling glue or adhesive plaster off a hairy leg. X rays show an area of atrophy around the thread of the screw, and this makes extraction of the screw easy.

The first position is, therefore, one of extension and of manipulation of the fragments, the deformity being corrected and an additional length given to the limb. The attainment of the latter is accomplished in two to three weeks by continued and steady traction on the soft parts of the thigh, the supporting slings controlling the fragments as desired. Enough callus is, as a rule, formed in eight weeks to hold the fragments in the desired position, and the first stage is thus terminated.

Second position.—In the second position the body-weight extension is no longer allowed, so that the limb lies passively in the splint. A knee-flexing arm is applied to the Thomas and movements begun. The second stage is, therefore, one of passive hardening of the newly formed callus, and is utilised also for movements of the knee.

Third position.—After three to four weeks a walking calliper is applied and used for two to four months. This period is one of active hardening of the junction of the fragments, and prepares for the time when the patient can discard all appliances with safety.

All the upper third malunited fractures were treated on Sinclair's net-bed, and it is impossible to over-praise this excellent means of double abduction and extension in the first stage. Frequent skiagrams must be taken, especially in the first stage of the treatment, anterior and lateral views being necessary. Massage of the knee and patella and muscles of the thigh is begun early, as is also electrical stimulation of the quadriceps.

Type of Suppuration after Osteotomy.

The outstanding feature in the majority of cases in which osteotomy was done for mal-union was the occurrence of suppuration, and this of a peculiar and apparently characteristic type. It will be seen from the table appended that all but two of the cases operated on had been healed for periods varying from two to ten months, and the greater number of these suppurated after osteotomy was performed. This fact suggests that the organisms concerned remained latent in the tissues, either in the soft or bony parts or in both. It has been demonstrated by other observers that organisms do exist, and remain latent in scar tissue and in and around foreign material in wounds which have been healed for some time. It is a common experience to see a "flare up" nowadays in a stump or limb many weeks after complete healing, causing sometimes a transient inflammation, sometimes suppuration, with the "melting away" of an old scar. The presence of a sequestrum is also a common cause of the above state of affairs, and it is possible that dead bone may not reveal its presence for many months and then show itself in the way mentioned. Skiagrams occasionally show opacities in some of the long-standing cases, suggesting dead bone, and yet the wounds healed up without operation. How long and how many of these cases will continue healed remains to be seen in the future. In some of the cases to be described the infection following the operation was undoubtedly derived from the bone, for cavities containing purulent material were seen during the operation in the newly formed bony parts.

Results of Examination of Pus and Bacteriological Report.

The pus is thick, dirty yellow, abundant, and has a most characteristic foul, strong, fæcal-like odour, making the vicinity of the patient most offensive. The pus from a number of these cases was examined with a view to demonstrating the presence of spore-bearing anaerobes. No spore-bearers, however, were shown. The pus contained abundant organisms of the proteus and coliform types which produced very foul cultures. Staphylococci were constantly present; streptococci also in most cases. On one occasion cultivation of a small piece of scar tissue removed at the time of operation grew *Staphylococcus aureus* only.

Course of Events following Osteotomy.

Drainage is provided in all cases, as for two or three days the oozing of blood derived from the raw bony surfaces is considerable. The amount of shock was small in those cases in which the operation did not prove very difficult, where little blood was lost, and where gas and oxygen with ether was the anæsthetic used. Some shock would seem to be produced by hammering upwards against the hip-joint. It is odd that even after six and eight months, suppuration, so profuse in amount and clinically so alarming, should occur. The thigh swells up, becoming tense, shiny, and tender. Two to three days after operation the oozing blood becomes purulent and offensive. The next day or so a profuse discharge of pus is obtained. The temperature reaches 101°–103° (see Chart 2) about the fifth day and a corresponding rapid pulse is obtained (100–120). If the draining proves adequate the temperature begins to fall step-ladder fashion, becoming normal about the tenth day. Improvement is first detected by wrinkling of the skin taking the place of the glossiness, and appears first when the temperature is beginning to come down. The progress of the case depends on the efficiency of the drainage. The stitches of the 8-in. incision do not attempt to give, and there is often no redness of this part, or, indeed, of the thigh as a whole, due to the fact that the pus is among the muscles and deep to the strong limiting fascia lata of the thigh.

The attenuated organisms are not of a virulent character, for after the natural forces of the body are mobilised and brought into the field of action, a matter of some five days, the enemy is soon overcome. A profuse foul discharge may be kept up for some time, but the temperature and pulse keep down. A subsequent rise of temperature indicates the collection of a pouch of pus requiring an outlet. (See Chart 3.)

Necrosis following suppuration after osteotomy necessitated sequestrotomy in five cases. In doing the operation of sequestrotomy the old scar is used, a sinus being present here as a rule. A 4-in. incision is usually made down to and through the periosteum. The latter is raised and the bone chipped away around the cloaca until the cavity in the femur is exposed and can be thoroughly explored for the removal of the sequestra. At the same time the cavity is converted into a pond with sloping edges to hasten its obliteration and healing of the case. Sequestrotomy was not done early in the cases mentioned. The operation should be left until it is time for the patient to walk or until he actually has walked about in a calliper for three weeks or so. Obviously, with firm union such an operation can be more safely and thoroughly done.

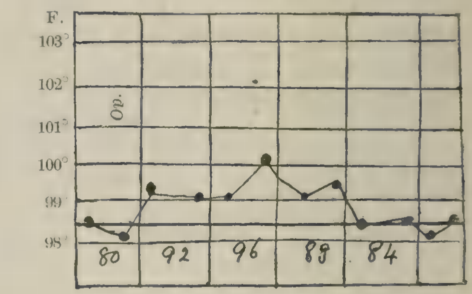

CHART 1.—Osteotomy without sepsis.

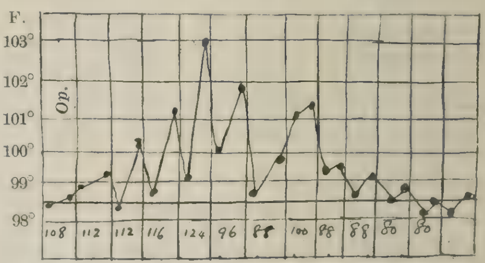

CHART. 2.—Osteotomy complicated by sepsis.

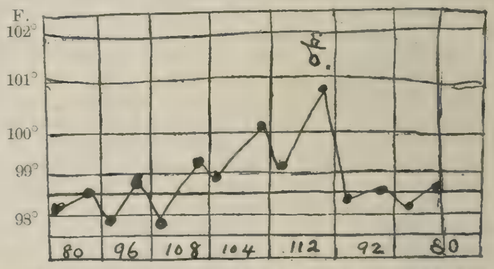

CHART 3.—Pocketing occurring later, after osteotomy and sepsis.

The Operation of Choice and the Prevention of Bad Results.

It may be argued that it would be better, in view of the suppuration occurring, to divide the femur some distance away from the site of fracture in a fresh field free from lurking organisms. The results obtained, however, by the operation as done by Mr. Harold Wilson leave no doubts as to the method of choice. The only disadvantage, suppuration, has not proved dangerous when properly provided for.

The advantages of this operation are:—

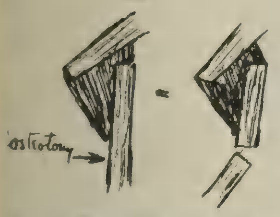
(1) *Increased length*—an important factor when 2 in. or more (see Table of results) may be added to the length of the limb.

(2) *Improvement of alignment and correction of deformity.*—In cases where there is angulation it is most important that in the corrected position the fragments, if not in end-to-end apposition, should at least lie parallel to one another and so produce a straight thigh. The importance of this cannot

be exaggerated, especially in the deformity resulting from the backward sag of the lower femoral fragment.

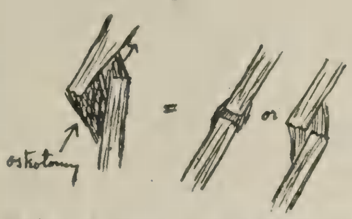
The two methods may be represented as shown in Diagrams A and B.

A



Result.—Correction of alignment to a large extent, but shortening still remains.

B



Method of choice.—Result: Better correction of alignment and correction of shortening.

The causes of angulation and bending of the femur are:—

(*a*) *Want of care in the first position.*—Mere plating of a femur and treatment without a slight extension on the limb to keep the muscles occupied leads to union, often in a bowed position; indeed, the strong plate bends also if the screws hold.

(*b*) *Assuming the third position too early* or discarding the calliper too soon.

(*c*) *Walking when angulation is already present* to a greater or less degree.

(*d*) *Frail union*, as when only half the broken surface of the femur throws out callus; when loss of bone results in a large gap made good by callus; when there is partial union only, through the loss of fragments; if end-to-end apposition is obtained with little visible or palpable callus.

(*e*) *Sepsis.*—When a sequestrum is present sepsis does not prevent formation of callus, but occasionally seems to hinder proper calcification, with the result that bowing occurs on walking, or even by the traction of muscles while the limb lies in bed between sand-bags.

As already mentioned, premature walking is not the only cause of bowing of the thigh; it can occur by muscular action alone while the limb lies passively in bed. The commonest direction of bowing in these cases is outwards, and seems to be due largely to the pull of the adductor muscles on the lower fragment in some cases. The upper third fracture, or osteotomy, particularly offends in this way, the bowing outwards being primarily due to the extraordinary tendency to abduction of the upper fragment.

Such cases are treated by being put up again into the first position of extension at once, and no difficulty is experienced in getting good alignment again in a few hours or days. A fortnight in this position and a further three to four weeks in the second position warrants a further trial with the walking calliper. The case that has once "bent" needs to be watched, for it may recur, and a further period of treatment, as just described, may be necessary. Bowing of the thigh is often the cause of a surprisingly large amount of shortening, $1\frac{1}{2}$ and 2 in. being common in the slightly curved cases, and this is especially true of upper-third fractures.

Methods for the Correction of Bowing.

(1) *Re-fracture by breaking, without open operation.*—The site of fracture is snapped across and the corrected alignment maintained by treatment in the first position with the help of slings pulling the fragments into position. This method, of course, would apply only to recent cases where there was no great overlap, or to cases of frail union which would not mould into position, but would crack across the narrow bridge of callus instead. Simple fractures are safer to deal with in this way than compound, owing to the risk of suppuration ensuing in the latter.

(2) *Active moulding by manipulation*, with or without an anæsthetic, depending on the case and resistance expected. This is done by trying to bend the femur back gently into the straight position over one's arm. This, as a rule, requires to be done within three months of the original fracture, but the amount and density of the callus, as shown in a skiagram and the history of the case, must determine whether moulding is possible. Upper-third cases are difficult to treat by this method, especially when the upper fragment is a mere stump. The case is then treated in the first position, &c., as just described for recent bowing of the thigh.

(3) *Passive moulding* by treatment in the first position—i.e., continuous pulling and the help of slings or pressure pads, which help to push the bent thigh straight. This method often, in combination with active moulding, is the method to be preferred. For upper-third cases the net-bed is most successful. This method, again, depends for its success on the time since the fracture and the amount and quality of the new bone formation.

Pte. R., admitted 13 weeks after simple fracture of upper third. Firm union. Much outward bowing due to abduction of upper fragment. (Fig. 3.) Shortening $1\frac{3}{4}$ in. Treated on net-bed with 24 in. drop. Skiagram three days later showed no improvement. Ten days later some alteration in position had taken place quite distinctly. After 14 days' continuous pulling, the alignment as shown in Figs. 11 and 12 was obtained. Shortening now $\frac{1}{2}$ in. Bowing absolutely corrected. Treatment, before walking in a calliper, lasted nine weeks.

Pte. Y. Compound fracture, mid-third, of several months' standing. Wound healed. No overlap of fragments, firm union. Net-bed had to be used owing to the outward bowing of the femur being too great to allow of the application of a Thomas splint. Shortening 5 in. Ten days later a flush appeared around the scarring. T. 103°. The flush spread up and down the thigh in the usual way, then subsided in three days. X rays showed the femur straightening out, and four weeks' pulling produced the desired result. The second position was maintained for three weeks. Deformity corrected; shortening 2 in. To prevent the tendency to bowing the thigh was put in plaster, over which a walking calliper was worn. Suppuration would probably have ensued in this case if osteotomy, or cracking the femur across, had been done. A similar result might have followed forcible moulding, so the method of passive moulding was probably the shortest and the safest in the long run.

(4) *Osteotomy.*—Cases of bowing with a great deal of overlap should be treated by osteotomy through the plane of union, as described below.

Pte. C. (Figs. 5 and 6) shows the results of such treatment on a net-bed. Besides the angulation present there was 4 in. of shortening. The result was a perfect thigh with $1\frac{1}{2}$ in. shortening.

Pte. W. had similar treatment, except that it was thought better to wire the fragments together to hold them in position until union occurred. The overlap was very small, the shortening being due almost entirely to the extreme abduction of the upper fragment. Profuse and long-continued suppuration followed operation. Shortening reduced from $3\frac{1}{2}$ in.–$\frac{3}{8}$ in. Deformity corrected.

Osteotomy the Operative Technique.

The operative technique, as adopted by Mr. Harold Wilson for the treatment of malunion, is as follows:—

A large incision (6 in. to 8 in.), utilising the excision of a scar or unhealed sinus when these are present, is made on the outer side of the thigh. The incision is so placed as to enable the lower end of the upper fragment to be freely exposed, for the latter serves as a guide for the insertion of the osteotome into the plane of union. The lower fragment usually lies deep to the other and on its inner side, its upper end lying high up when there is much overlapping. The incision cuts cleanly through the skin, fascia lata, and muscle, down to the bone, incising the periosteum from end-to-end of the wound. Bleeding from several arteries, branches of the external circumflex, is often severe and these require tying. It is better to work without a tourniquet.

The thickened periosteum is elevated completely off the fragments, a scalpel being necessary in places where scarring binds the periosteum down. The periosteum having been raised and a free exposure of the site of union obtained, a broad, slender Albé osteotome 2 in. wide is inserted under the lower end of the upper fragment if possible, and the junction of new bone between the fragments divided carefully in an upward direction. Just how the osteotome is placed depends, of course, on the disposition of the fragments, the aim being to divide the new bony cement and not the original main fragments. The latter are liable to splinter if care is not taken, and one object of the broad osteotome is to try and prevent this.

An assistant now holds the foot and moves the leg as directed, to enable the operator to make sure that division is complete and to give him an idea how the fragments are eventually going to lie in relation to one another when extension is applied. Any scar tissue or props of bone, inhibiting free movement or preventing apposition, are removed. In some cases simple division may be all that is necessary. In others, division of union and shaping of the ends of the bone may be deemed advisable, due allowance being made for the subsequent lengthening which will occur as the result of continuous extension. In others, again, division and the free removal of props of new bone (see Figs. 9 and 10) is necessary before correct alignment by pull is possible, as these bony growths keep the fragments apart. The wound is irrigated with hot saline and tags of tissue removed. The muscle and covering fascia are sewn up with continuous catgut and the skin sutured, drainage being provided by a large tube carried down to the bone at the upper end of the incision. An additional tube is sometimes inserted about the middle of the incision, or posterior drainage is provided, especially when suppuration is expected. The limb is then put up into the first position in a Thomas's splint or a net-bed, as the case requires, and treated as an ordinary fractured femur. In simple malunited fractures, or when no suppuration is expected, the drainage-tubes are removed in 48 hours.

Further treatment.—Most of the further treatment has been described above. An X ray is taken three or four days after the operation, and any adjustment required is made then. Large quantities of callus are usually throw out in these cases of osteotomy, and there is little fear of non-union provided the suppuration problem is dealt with effectively. Thirteen weeks usually sees the patient on his feet in a walking calliper, although a small sinus may still be present and the case may require a sequestrotomy at a later date. The skiagrams shown are typical examples of the results obtained.

Summary of Methods of Treatment for Malunion.

(1) Deformity with much overlapping (i.e., shortening): Osteotomy through plane of union.

(2) No deformity but much overlapping (2 in. or more): Osteotomy through plane of union.

(3) Deformity with little or no overlapping (recent case): (*a*) Moulding into position; (*b*) or actually cracking the bone across and treatment by splinting and extension.

(4) Deformity with little or no overlapping (old case with firm union): (*a*) Re-fracture if possible without an open operation; (*b*) open osteotomy.

In conclusion, I desire to express my thanks to Sir Anthony Bowlby for the introduction. To Mr. Harold Wilson, who initiated the femur work in this hospital and was until recently in charge of the femur wards, I am deeply grateful for kind and useful guidance. Lieutenant-Colonel R. J. W. Oswald, O.B.E., R.A.M.C. T., commanding the 1st London General Hospital, has kindly consented to allow the publication of these cases.

THE MEANING OF TACHYCARDIA.

BY R. McNAIR WILSON, M.B., CH.B. GLASG.

(Read before the Fellowship of Medicine.)

AFTER the recent influenza epidemic a number of cases presented themselves in which a rapid pulse-rate appeared to be the chief symptom. The clinical picture was that of convalescence, a rather slow convalescence. The patients tended to be breathless and occasionally complained of feeling giddy. If their attention had been called to their pulses they usually showed anxiety at the fast rate. On the other hand, they were often quite unaware that their pulses were quick at all. Many of them were apparently well and capable of considerable exertion. Other cases of tachycardia have been met with in patients suffering from dysentery, chronic malaria, chronic trench fever, and other diseases.

The chief physical sign is the quick pulse, which may reach 120 or higher, but which is commonly between 90 and 110. This pulse quickens still further on exertion, running up often to 160, as recorded by the polygraph. Moreover, there is a normal "release" with atropine which, when given in doses of 1/33 gr. subcutaneously, produces an acceleration of 20–25 beats a minute.

This normal release led to the view that the vagus nerve in these cases is normal in all respects, but evidence gradually accumulated which pointed to a different conclusion. It was found that if the patients were instructed to take a long deep breath and hold it marked slowing of the pulse (Fig. 1) or a marked loss of pulse volume with quickening was wont to occur. After atropine this phenomenon could not be elicited. (Fig. 2.) Moreover, in a series of controls who had not recently suffered from any acute illness and who were not the victims of "rheumatism" no slowing and no loss of volume occurred. It was concluded that the phenomena were abnormal, and that they depended on the vagus for their production.

The next question is: The vagus is not less excitable than normal in these cases; is it more excitable than normal? It was argued that there are two functions of the heart which are distinct, augmentation and acceleration. Augmentation is accomplished when a more prolonged or larger diastole is followed by a larger systole. Both cardiac nerves, the vagus and the sympathetic, take part in this mechanism, the vagus by increasing the length of diastole, the sympathetic by responding in systole. Acceleration, on the contrary, is a purely sympathetic phenomenon. Now the effect of atropine is, for the moment, to inhibit the vagus, and so to cause the nervous mechanism of augmentation to break down. Thus acceleration alone remains if the circulation is to be maintained. This is the so-called "release of the pulse" under atropine. If, however, atropine were to be given in a dose small enough not to inhibit the vagus but somewhat to lower its excitability, we should discover by the result whether or not the nerve was hyper-excitable in those cases of tachycardia. For if the tachycardia should be due to an excessive vagus pull compensated by acceleration the act of lowering the excitability of the vagus to normal must cause the pulse to slow down; compensatory acceleration would no longer be necessary.

Four cases with pulse-rates at rest, varying from 108 to 85, were selected; all these showed tachycardia when not at rest, and one control who was healthy was added to the number. A dose of 1/200 gr. atropine was given intravenously. The results are shown in Fig. 3.

It was then seen that a very small dose of atropine was capable, in these cases of tachycardia, of slowing the pulse markedly. In the control case (*b*), on the contrary, quickening took place. Clearly, then, a slight lowering of vagus excitability produced slowing, or, in other words, the acceleration was compensatory to excessive vagus action. Numerous other experiments on the same lines were carried out with the same results.

Function of the Vagus.

It appeared that the conception of the vagus, which was expressed by Luciani, the Italian physiologist, as the "nerve of diastole," was justified. For this nerve would not seem to be inhibitor in the narrow sense, but rather to act by increasing the filling time of the heart in response, no doubt, to stimulation from the cortex. A vagus "pull" thus initiates a period of increased cardiac effort, what is spoken of as increased "output per beat." But a prolonged diastole with consequent increased filling of the heart presupposes a more powerful systole. In other words, the whole level of cardiac activity is raised. If the heart, on the other hand, should not be able to make this response in each individual beat it will require to add acceleration to augmentation—it will require, that is to say, to increase output per minute, since output per beat is not sufficient.

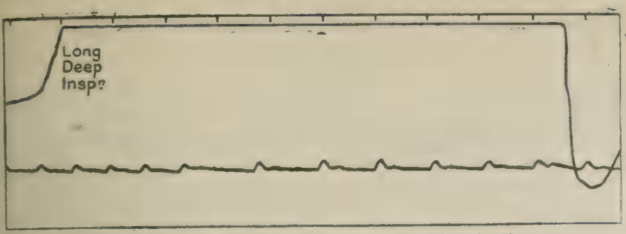
In cases where the vagus is hyper-excitable there will always be a tendency every time that influences pass from the cortex to the medullary centres —i.e., on excitement or calls for effort—for the vagus to overdo its part and to prolong diastole unduly. The result must be a compensatory acceleration if the necessary level of activity is to be maintained. Professor F. A. Bainbridge, dealing with the purely muscular question, has recently written:—

> "In response to a moderate increase in venous inflow a comparatively slight dilatation enables a powerful (thick-walled) ventricle to increase considerably its output per beat, and still to empty itself almost completely at each beat. Hence a slight increase in the pulse-rate will bring about a sufficiently large output per minute to prevent any accumulation of blood on the venous side, and therefore to prevent an appreciable rise of venous pressure. Placed under the same conditions a feeble (thin-walled) ventricle, even when dilated to its physiological limit, may be unable greatly to increase its output per beat and may be far from empty at the end of systole. In these circumstances considerable acceleration of the pulse will be necessary to increase the minute volume of the heart sufficiently to balance the venous inflow. In this way acceleration of the pulse can compensate for lessened contractile power in maintaining the output of the heart per minute."

The work described above suggests that an over-active vagus imposes a similar strain on a heart not necessarily weakened at all. But there is another aspect of the question, which must now be introduced. During the work on tachycardia a case was encountered, tracings from which, and from another similar case, are shown. (Figs. 4 and 5.)

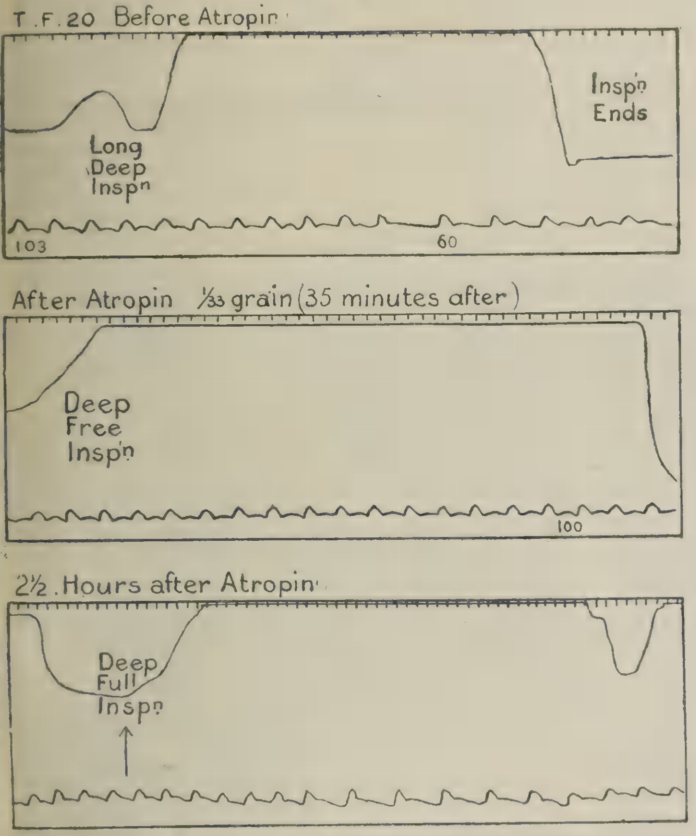
In this case on deep inspiration there was a preliminary slowing from 95 to 75. And then quite suddenly the blood pressure, which had been 120 mm. Hg systolic, fell to 80 systolic, the pulse ran up to 100 and later to 110, and the patient felt faint. Thus both slowing and loss of volume were seen in the same tracing. It appeared that

FIG. 1.



Trench fever. Marked slowing on deep inspiration.

FIG. 2.



Slowing of pulse on deep inspiration, removed by atropine.

vagus stimulation by deep inspiration had in this case:

1. Made it impossible for the compensatory acceleration, the tachycardia, normally present to be kept up. Consequently the pulse slowed and acceleration was dropped, leaving only augmentation. There was a fall of blood pressure of 5–10 mm. Hg systolic.

2. Finally placed the heart under such a strain that the contractile power was unable to cope with the over-filling, systole for diastole, so to speak. The organ was incapable, that is, of emptying itself or nearly emptying itself in a single systole. The mechanism of augmentation had, in fact, broken down.

Thus excessive vagus stimulation produces the same effect as inhibition of the vagus by atropine. The reciprocal action of vagus and sympathetic can be dislocated in two ways—by "cutting out" the vagus, or by increasing the irritability of this nerve to an excessive degree. In both cases the only resort left to the heart is acceleration, which at once takes place.

Types of Acceleration.

There are thus three types of acceleration, all differing in their means of production:—

1. The type represented by the ordinary case of tachycardia, in which acceleration has been added to augmentation. The blood pressure is usually normal or slightly higher than normal—e.g., 140 mm. Hg systolic.

2. The type occurring when augmentation is abolished by atropine. Blood pressure slightly less than normal.

3. The type occurring when augmentation is abolished by excessive irritability of the vagus. In this case the blood pressure falls sharply, to 80 mm. Hg in many cases, and the patient feels faint. This type of acceleration is seen in the very severe cases of septic fevers, in pneumonia which is running to a fatal issue, and in other cases. It can also be

FIG. 3.

produced, as has been shown, by vagus stimulation in some cases of tachycardia.

Tachycardia by this showing is a compensation to a hyper-excitable vagus. It remains to suggest that the vagus is so rendered hyper-excitable by the action of a toxin. In the accompanying chart from a case of trench fever this can be seen. (Fig. 6.)

It will be observed that across the chart there is a gradual decline of the temperature curve and a gradual rise of the pulse curve. Moreover, the acceleration of the pulse towards the end of the chart increases with each slight rise of temperature. If the views enunciated are correct, the explanation is that while at first the toxin was powerful enough to render the vagus unduly excitable, and so to prevent acceleration towards the later stage of the illness, the toxin had lost power and acceleration could occur. In point of fact, the blood pressure, which had been subnormal at the beginning, became normal later when the compensatory acceleration was established. The same tendency to the establishment of tachycardia as fever declines can be observed in many influenza charts and in other diseases. When tachycardia is established the patient is better in his strength than before this takes place.

Conclusions.

1. Tachycardia in a man who is up and about is compensatory in character, the addition of acceleration to augmentation.

2. It points to the presence of a mild infection, and can be removed only by removing the infection.

3. There is evidence that the action of the toxin is directly on the cardiac vagus.

DISLOCATION OF CERVICAL SPINE.

REDUCTION UNDER ANÆSTHESIA.

BY J. PHILIP BUCKLEY, M.D. CANTAB., M.S. LOND., F.R.C.S. ENG.,
HONORARY ASSISTANT SURGEON, MANCHESTER ROYAL INFIRMARY.

IN June, 1918, an officer was admitted under my care at a base hospital in France, his field medical card bearing the diagnosis, "Injury to right shoulder." I saw him in bed soon after admission, and finding him cheery and apparently fit, and a cursory examination of the right shoulder revealing no gross lesion, I turned my attention to apparently more serious cases. Next morning when I came into the ward he was up and walking about. It was obvious at the range of the few yards which separated us when I observed him that he had a marked deformity of the cervical spine. His head was held forwards with the chin approximated to the chest, and there was a definite angular deformity at the back of the neck. I at once ordered him back to bed.

The history of the case was as follows. He was riding a motor-cycle in the dark, and coming into contact with another vehicle he was thrown off. He was temporarily "knocked out" and was taken back to his unit, where he was seen by the medical officer, who sent him to bed. As he was not better in the morning he went to the C.C.S. He reached the base about three weeks after the accident, and when I gently reproved him for having got up he seemed surprised, and said he had been accustomed to get up at the C.C.S., and had even played badminton there.

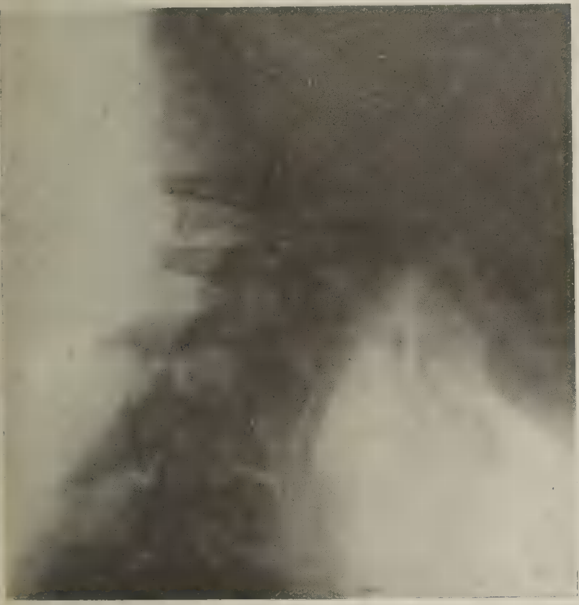

FIG. 1.—Showing dislocation of cervical spine between fourth and fifth vertebræ.

I had an X ray photograph taken. (Fig. 1.) This shows a dislocation of the cervical spine between the fourth and fifth vertebræ. There appears to be no gross bony lesion. The articular processes of the fourth and fifth vertebræ are just clear of one another; the spinal column above the lesion is displaced forwards, and rotated forwards to an angle of 140° with the spine below the lesion. The patient was very cheerful and felt well, and beyond the marked deformity, slight referred pain over the right shoulder (hence the F.M.C. diagnosis), and slightly increased knee-jerks did not present any symptoms of spinal injury.

Reduction under Anæsthesia.

As it seemed a pity to condemn a fine young man to live the rest of his life with his chin sunk upon his chest, after careful consideration I decided to attempt reduction under an anæsthetic. I first made a poroplastic splint to embrace the back of his head with two side wings around the temples, to extend down the neck and well down the dorsal spine, with two lateral wings to embrace the chest. I made this to fit a hospital orderly about the same size as the patient. Careful precautions being taken to keep the head, neck, and body fixed during the process, he was anæsthetised. When he was well under the anæsthetic I exerted traction on the neck, at the same time making leverage backwards. Though there was no reduction "with a click," yet I was able so far to effect a reduction that external signs of the deformity disappeared. The splint which I had prepared was then applied with the aid of strapping and a bandage. This splint I afterwards reinforced with a strip of metal riveted to it along the mid-line. He suffered no ill-effects from the manipulation.

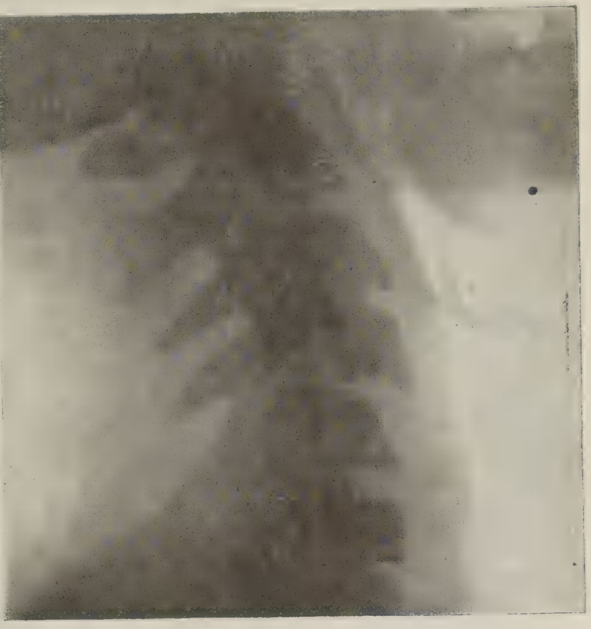

FIG. 2.—Showing natural curve of neck restored.

The result of the manipulation is shown in the X ray taken subsequently. (Fig. 2.) It will be seen in this that the natural curvature of the neck has been restored; there still appears to be some displacement forwards of the fourth upon the fifth cervical vertebra, but I think this is not as great as at first sight it may appear, since it will be noted that the front of the body of the fifth vertebra shelves more abruptly upwards and backwards than the remainder of the vertebræ, rather suggesting that it has been damaged by the body of the fourth vertebra grinding over it in the act of dislocation, although no loose fragment of bone can be seen.

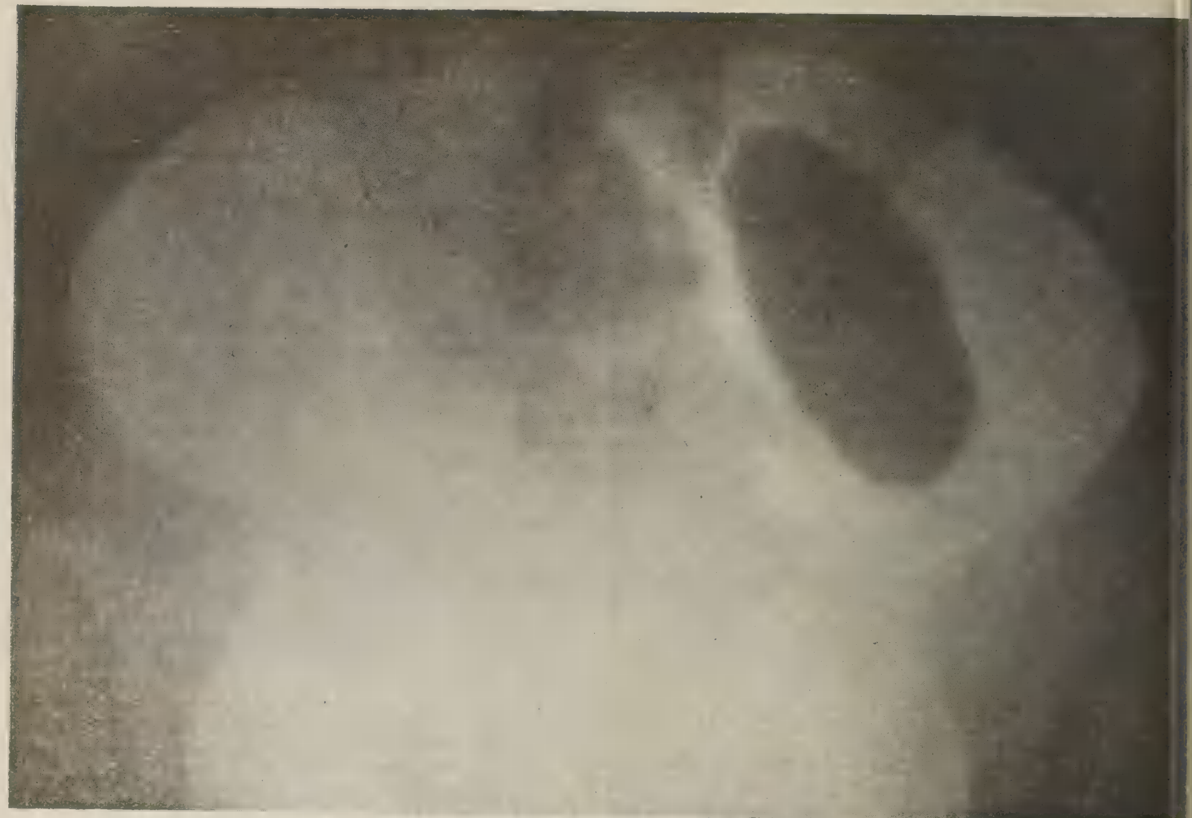
Regarding the after-history of this case I have no information beyond the fact that, about nine weeks after the above-mentioned manipulation, I met my recent patient, still wearing my splint, but quite happily dining, at a restaurant. I spoke to him, and he told me that he was doing all right, but that his neck still felt weak if he left off the splint.

A CALCULUS OF UNUSUAL SIZE

REMOVED FROM THE URETER BY OPERATION.

By FRANK KIDD, F.R.C.S. Eng.,
SURGEON TO, AND SURGEON IN CHARGE OF THE GENITO-URINARY DEPARTMENT, LONDON HOSPITAL.

I HAVE never seen a stone as large as the one here described removed from the pelvic portion of the ureter, and I should think it must be a record. A stone of such dimensions could hardly have developed in a normal ureter. The ureter was dilated because of the congenital stricture of its mouth, which explains how it became possible for so large a stone to grow therein. Apparently the kidney and ureter had become infected with a mild strain of staphylococcus, which had decomposed the urine and caused a deposit of phosphates which had developed into a stone; in other words, the stone was probably secondary not only to the stricture, but also to an infection.



X ray photograph showing actual size of calculus.

The patient, a young man of 18 years, was admitted to my wards at the London Hospital on August 31st, 1919. He had previously been seen by Mr. A. J. Walton, who very kindly transferred him to my care. In 1907 he had had a stone in the bladder, which had been crushed and removed. In 1908 he had had slight pains in the right loin. After that date he had had no more trouble until eight weeks before admission. At that time a dull, aching pain developed in the right iliac fossa, which lasted four days. A few weeks later the pain recurred and became more acute and was sufficiently bad to lead him to come up for advice and relief. He had never had increased frequency of micturition or any other symptoms.

On examination the urine was acid, contained no albumin, but a moderate haze of thin pus. The deposit consisted of red blood corpuscles, pus cells, ac phosphate crystals, and the *Staphylococcus albus.* T X ray examination showed a large oval shadow in t region of the upper portion of the right pelvic ureter, shown in the appended photograph.

On Sept. 4th I administered spinal anæsthesia. Wi the cystoscope I could see prolapse of the mouth of t right ureter, with cyst formation and intermitte ballooning of the cyst as the urine came down from t kidney. This, although a rare condition, is w recognised by urologists, and has been named "ureter cele." The primary condition is a congenital strictu of the mouth of the ureter, with secondary dilatation the ureter and prolapse of the dilated ureter into t bladder. By rectal examination the dilated uret could be felt, but the stone was too high up in the pelv to be felt.

Operation.—I cut down in the right groin through muscle-splitting incision 3¼ in. long, as described by m in THE LANCET of June 7th, 1913. The peritoneum wa pushed aside and the ureter identified at the pelv brim as a thin-walled dilated tube the size of a coil small intestine. The stone lay below the pelvic bri fixed to the side of the pelvis by peri-ureteric fibrosi The ureter was opened well above the stone by a longitudinal incision 1½ in. long, and pus and urin gushed out. The stone lay fixed in a large pouch; the upper end of the pouch was cut open and the stone was easily removed. Bougies could then be passed int the bladder. The wall of the ureter was re-stitched with fine catgut in two layers, a small tube was placed at the site of the stitching and brought out through the abdominal wound: the abdominal wound was stitched up with catgut in layers. The operation took 30 minutes.

Course.—A few drops of urine leaked from the tube for 24 hours: after that there was no more leakage, and the tube was removed. On the fourth day the stitches were removed; on the eighth day the wound had healed by first intention, except for the tube hole. The patient left the hospital on the sixteenth day, soundly healed and with no further symptoms. The stone measured 2¼ in. in its long diameter and 1 in. in its short diameter, and weighed 1 oz. It consisted of phosphates, with a trace of oxalates, and contained no cystin, no carbonate, and no uric acid.

Comments on the Case.

It is interesting to note how very few symptoms had been caused by the stone. As a general rule, the larger the stone the fewer the symptoms. Since I wrote my paper on the removal of ureteric stones I have seldom found it necessary to operate for stones in the lower portion of the ureter. Most ureteric stones in the pelvic portion of the ureter lie just above the bladder, and are prevented from entering the bladder by the narrowness of the opening of the lower end of the ureter. I find by experience that I can slit up the mouth of the ureter with a pair of operating scissors, through the operating cystoscope, lubricating the stone with parolene, and that a few days or weeks later these stones are passed naturally without any further trouble. In this case the stone was so large that it was clearly necessary to operate by open incision.

B. S. Barringer[1] describes a case of double ureterocele with a small stone lying in one of them. He cut off the top of the ureteroceles with the operating cystoscope, and the stone was then passed naturally. I have previously seen two cases of ureterocele; in one I treated the condition by open operation, and in the other I cut off the top of the projection through the operating cystoscope; on both occasions results were satisfactory. I hope to operate at a later date on the ureterocele present in the case reported here.

DIVERTICULITIS.

Being some Remarks made in the Course of a Discussion at a Meeting of the Section of Surgery (Subsection of Proctology), Royal Society of Medicine, on Jan. 7th.

BY G. GREY TURNER, M.S. DURH., F.R.C.S. ENG.,
HONORARY ASSISTANT SURGEON, ROYAL INFIRMARY, NEWCASTLE-ON-TYNE.

MY first introduction to the subject under discussion was in the year 1903, when, as surgical registrar, I saw Professor Rutherford Morison excise what was supposed to be a malignant growth of the sigmoid in a man of 60. On examining the specimen I found that it was an example of diverticulitis. There were 13 diverticula, with great inflammatory thickening of the bowel wall, but no lesion of the mucous membrane. The man died, and at the post-mortem many diverticula were found from about the middle of the transverse colon to the point at which the sigmoid had been divided, but none in the lower segment of the bowel. The condition was at once recognised, and was correctly described in the hospital notes.

This case is of some interest, because it has been stated by Sir Berkeley Moynihan in his Cavendish lecture for 1912 that he operated in 1906 "upon the first case recognised as chronic diverticulitis of the sigmoid flexure in this country." I always regret that the example to which I have referred was not published at the time, for it would have stimulated an earlier interest in this particular subject. But there was really no excuse for ignorance in the minds of inquiring surgeons, for a well-illustrated abstract of the paper by Ludwig Schreiber appeared in the *Medical Review of Reviews* about that time, and in THE LANCET for Oct. 24th, 1903, Sir John Bland-Sutton wrote a most suggestive paper "On the Effect of Perforation of the Colon by Small Foreign Bodies, especially in relation to Abscess of an Epiploic Appendage."[1]

Since then several examples have come under my notice, and they have illustrated all the clinical conditions which have been described.

Description of Cases.

I would like to refer to three cases of particular interest.

The first is that of a female patient, aged 34 years, on whom I operated in 1904 for what was diagnosed as appendicitis with abscess.[2] I found a hard mass in the ascending colon which so closely simulated a malignant new growth that I thought it best to excise it. On examining the specimen I found the explanation to be an inflammation around a diverticulum in the commencement of the colon. There was also another quiescent saccule on the caput. No other diverticula were noticed in the large bowel during the course of the operation. The patient made a good recovery, and was living and well 15 years later.

The second case must be almost unique. It is that of a man 57 years of age who was admitted to the Newcastle Infirmary in the year 1902 suffering from retention of urine with general peritonitis. As it had not been found possible to relieve the condition by catheter an attempt had been made at his home to puncture the bladder suprapubically, but only liquid fæces escaped through the trocar. The man soon died, and at the post-mortem I found what I then took to be a malignant growth of the sigmoid, and just above this growth was a large hole leading into the bowel; there was fæcal extravasation with general septic peritonitis. On looking for an explanation I discovered, free in the recto-vesical pouch, a large gall-stone which had evidently ulcerated through the sigmoid just above the growth. An examination of the gall-bladder showed a second calculus projecting from that viscus into the hepatic flexure. The condition was interesting enough, and the specimen was put aside for further investigation, but amid an abounding wealth of pathological material it was neglected until the year 1908, when I was especially interested in the question of gallstone ileus. On re-examination I then found that the condition was a typical example of diverticulitis, and that there was no question of new growth. Unfortunately the specimen has been mislaid, but I am able to show you a drawing which was made at the time.

The third case shows that peritonitis may occur as the result of ulceration of even a small and almost isolated diverticulum, for in this patient only three such diverticula were found after a careful search of the bowel, cut in serial sections.

Ætiology, Diagnosis, and Treatment.

As regards ætiology, I have the conviction that the condition will ultimately prove to be congenital in origin. This is in accordance with the general origin of the diverticula with which we are familiar in the various parts of the alimentary canal and in the bladder. In one of my cases, a man who died from peritonitis and who presented diffuse diverticula in the large bowel (42 in number), there were also two large sacculi in the bladder in relation to the left ureter. At the time the latter were attributed to an enlarged prostate, but extended experience of vesical pouches has led me to realise that in many cases these are certainly congenital in origin. We must freely admit that in their early stages all diverticula are probably symptomless, but that they are progressive and tend to give rise to trouble in the course of years. In fact, the distension which precedes pathological symptoms may not be quite complete even in late life, and this was borne out by an example of diverticulum of the duodenum the size of a thumb in a woman of 60, in which the mucous membrane at the apex was so thrown into folds as to suggest that it was capable of very much freer distension than had ever taken place.

---

[1] Since hearing Sir John Bland-Sutton's remarks at the discussion I have taken the opportunity of again carefully reading his paper, and find it full of renewed interest. There is an illustration of a diverticulum of the colon, and some of the cases were undoubtedly examples of diverticulitis, though the distinguished writer did not at that time divine what he now believes to be the correct explanation.

[2] A Case of Tuberculous Ulceration of the Ascending Colon Simulating Appendicitis, THE LANCET, Sept. 16th, 1905.

In the matter of diagnosis I have been struck by the very clear history which one can usually obtain *after* the event. In one case in which I excised the bowel under the impression that we were dealing with a malignant growth the man subsequently gave a wonderful history of recurring slight inflammatory troubles extending over a period of as long as ten years. A careful scrutiny of the histories furnish many points which help in the recognition of the earlier stages of the disease.

There is a further case bearing on the question of treatment which I should like briefly to mention.

It was that of a lady, 55 years of age, who gave a six months' history of pelvic inflammatory trouble, with severe pain of eight days' duration. A big tender mass was felt in the left side, and a diagnosis of tubal inflammatory mischief was made with some confidence. At the operation I found that the mass originated in the sigmoid, and after separating the adhesions sufficiently to allow of it being properly examined I detected multiple diverticula in the bowel higher up, giving a clue to its origin. The affected portion of bowel was too low down to excise safely and make an anastomosis, and I did not at that time think that the condition justified excision with a deliberately permanent colotomy, so I determined on the latter expedient in the hope that the rest would lead to such a degree of resolution that the continuity of the lumen could be restored safely at a later date. After the operation the lower end of the bowel was kept free by repeated irrigation, but an attempt to pass a tube from the anus to the colotomy, or vice versa, was never successful. Six months later the involved portion of bowel would easily admit the finger, so the colotomy was closed. The patient remained perfectly well for 18 months, the bowels being opened regularly and without any trouble. At the end of this time she developed a very definite obstruction which would not yield to ordinary measures, and I had to re-make the colotomy. After this the patient always took great care of the lower bowel, and in consequence kept very well for nearly five years, when she commenced to have a little discomfort, and occasionally to pass a quantity of mucus per anum. Just seven years from the original onset of her trouble she again developed an inflammatory condition round about the lower segment of bowel, terminating in a large abscess which pointed and was opened at the lower part of the abdominal incision. The bowel was carefully examined, but there was no sign of new growth, and once again the condition subsided, leaving only a small mucous fistula at the site where the abscess was opened.

As this interesting condition becomes better recognised cases will undoubtedly be brought before the notice of surgeons at a much earlier stage, and we will frequently be called upon to decide what to do when we are confronted with the uncomplicated condition, or with cases of mild recurring inflammation. Under these circumstances in one instance, in a man of 38, I inverted several diverticula and sutured over the peritoneal pocket so as to convert them into polypi; others were too rigid and could not be dealt with in this way, but the patient was given directions as to the necessity of regulating his bowels and for abstaining from food at the slightest sign of discomfort in the lower abdomen. This operation was carried out 18 months ago, and up to the present the patient has had no further symptoms.

Under similar circumstances in a more recent case I squeezed out the contents of one or two diverticula into the bowel, but I found that it was not possible to invert them, and the abdomen was closed. When opportunity offers I would certainly cover up any exposed sacculi with the neighbouring epiploical appendices.

A CASE OF

ACUTE HYDRO-PNEUMOTHORAX

COMMUNICATING WITH THE STOMACH.

By J. W. TUDOR THOMAS, M.B., B.S.LOND., M.R.C.S.,
CAPTAIN, R.A.M.C. (S.R.).

THE following case of acute hydro-pneumothorax, resulting from an old gunshot wound of the chest, is of interest on account of its peculiar features. The patient recovered in spite of a communication between the pneumothorax and the stomach.

The patient was an East African native soldier who had been wounded in the chest by a machine-gun bullet four and a half months previously. The bullet entered 2½ in. outside the left nipple line in the sixth left intercostal space and was taken out through the eighth left intercostal space, 5 in. from the spine. He had no hæmoptysis and was discharged to duty after three months in hospital. During the next six weeks he was quite well, until the last week or so, when he complained of pain in the left side of the chest. The pain became suddenly worse, with severe vomiting, and he arrived at our hospital about two days later in a state of collapse, with no pulse at the wrist and almost in extremis. On examination there was found to be a left pneumothorax, the apex beat being in the right axilla. A needle was inserted, much gas was let out and some fluid. This was repeated in an hour's time, and he was given rectal salines, &c. The next day the chest was again tapped and much air and fluid was let out. The fluid on examination was found to be from the stomach. Intravenous and rectal salines were given and still the patient had no pulse at the wrist.

The next day an incision was made under novocaine in the sixth left intercostal space, letting out the air and fluid. Exploration by the finger showed the lung to be adherent on the outer side near the bullet exit wound. The heart could not be felt, the finger coming up on the posterior surface of the sternum. Passing the finger over the dome of the diaphragm a rift was felt leading down to the stomach. Two rubber tubes were inserted to drain the cavity. Two days later the pulse was quite appreciable at the wrist, and it was decided to do a temporary jejunostomy. The patient could not possibly stand a general anæsthetic, so this was performed under a local anæsthetic, 0·5 per cent. novocaine being used. The fundus of the stomach was found to be adherent to the diaphragm over a large area. The jejunum was brought to the parietal peritoneum, and sutured to it, with a No. 10 rubber catheter inserted and held in position by a purse-ring suture. The pulse and respirations were 120 and 28 before and after the operation. A few days later, by direct observation through the chest wound, using a forehead mirror, the extent of the cavity was investigated, and on the patient swallowing a little water it was observed to flow into the cavity in the chest through the communication with the stomach. A week after the operation a little dilute methylene-blue solution by the mouth caused no staining of the dressings on the chest wound. At this time the patient had an attack of influenza, which was prevalent. He had severe headache, which was relieved in less than an hour by aspirin gr. x. given in milk by the jejunostomy tube. A fortnight later a little liquid food by the mouth was given and gradually increased, at the same time the feeds by the jejunostomy tube were decreased.

At the end of another fortnight the patient was getting a fair diet of milk and malted milk by the mouth, so the jejunostomy tube was removed, a dry dressing being applied. There was no excoriation of the skin around the wound, and in less than a month after removing the jejunostomy tube the abdominal and thoracic wounds were both soundly healed. As the jejunum was brought up to, but not through, the parietal peritoneum, on removing the tube the wound closed up and healed rapidly.

The patient made a complete recovery, took his ordinary diet without any pain or discomfort, and said he felt exceedingly well. The lung expanded and the cardiac apex beat returned to about the normal position.

I am indebted to Lieutenant-Colonel R. F. Standage, I.M.S., Surgical Consultant, East African Field Force, for his advice and assistance in this case.

CASE OF
SUDDEN COMPLETE PROCIDENTIA RECTI
IN A YOUNG ADULT MALE.

BY W. R. M. TURTLE, M.B., B.S. LOND., D.P.H.,
SENIOR ASSISTANT MEDICAL OFFICER, WHIPPS CROSS INFIRMARY, LONDON, N.E.

THIS case appears to be of sufficient interest to record, as I believe the sudden formation of a complete prolapse of the rectum to be very unusual in a young adult.

S. H., a male, aged 26 years, was admitted to the Whipps Cross Infirmary on August 26th, 1919, suffering from complete procidentia recti. The prolapse formed a firm, œdematous, egg-shaped mass, the long axis of which was 5 inches and the short 4 inches. Hæmorrhoids were present in addition.

The history of the case was that once, when a very small child, the rectum came down and had to be replaced by a doctor, but the patient himself had no recollection of ever having had any trouble of this nature, until suddenly, on the day previous to admission, during the act of defæcation, the bowel came down.

On August 27th the mucous membrane of the prolapse was commencing to ulcerate in places. On that day I excised the prolapse by the method, so clearly described in Cheyne and Burghard's "Manual of Surgical Treatment," for "excision of the entire prolapse, when the prolapse involves the whole thickness of the bowel." Hæmorrhage during reflection of the mucous membrane was free, and troublesome to control, owing to congestion of the mass from partial strangulation and the presence of hæmorrhoids. Apart from this the operation presented no difficulty. The peritoneum covering the bowel was stitched to the parietal peritoneum and the cut edge of the bowel to the skin at the anal margin. The external sphincter was, of course, not touched at the operation, and quite half of the internal sphincter was left.

The patient made a good recovery; the wound healed without suppuration. There was incontinence of fæces for a month, and then control over the sphincter gradually returned. Two months after the operation control was fully established. He was discharged from the infirmary on Nov. 19th.

I have to thank Dr. J. C. Muir, medical superintendent, for permission to send the above notes on this case for publication.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

CLINICAL SECTION.

THE APPLICATION OF WAR METHODS TO CIVIL PRACTICE.

A MEETING of this section of the Royal Society of Medicine was held on Jan. 9th, Sir ANTHONY BOWLBY, the President, being in the chair.

The PRESIDENT gave an address on the Application of War Methods to Civil Practice, which will be found in full in the present issue of THE LANCET.

Discussion on the Address.

Mr. REGINALD VICK said that he had had an opportunity in Salonika of practising primary suture on compound fractures for a period of 18 months while at a general hospital on the Seres Road, to which large numbers of transport *accidents* were admitted. The invariable practice was to do primary suture on these cases, and the results were so uniformly satisfactory as to convince him that this method of treatment was as ideal as anything human could be and certainly as successful. The essentials for success were present—facilities for immediate operative treatment, a good theatre, and no reason for moving the patient until the wound and bones were healed. Since his return to England he had had the opportunity while working under Mr. G. E. Gask in the surgical unit, of treating all compound fractures admitted during their tour of duty. Primary suture had been performed in these cases, and where complete closure of the wound was possible the results were satisfactory. Where, owing to hæmorrhage, complete closure was impossible, secondary suture had usually been required at a later stage. In cases of compound fracture of the skull with the dura unopened, the end-results were excellent. It was important that operation should be performed at once, with complete removal of *all* damaged tissue and perfect splinting with subsequent immobility until healing was complete in cases of fractures of long bones. He had usually used ether in the final stages before closing the wound.

Sir CUTHBERT WALLACE remarked upon the difficulty in applying the Thomas splint in the case of women on account of their clothing. In fractures in civil life there was much more extensive injury to surrounding tissues than occurred in fractures under war conditions.

Mr. W. GIRLING BALL said that much had been done during the war in the bacteriological examination of wounds. In a series of 100 cases at the front treated by delayed primary suture 80 per cent. healed by first intention. Since his return he had endeavoured to carry out the same method of treatment. In the home hospitals cases were too often left to the inexperienced for treatment. This was difficult to avoid unless the house surgeon had been taught by someone who had actually carried out the method. He thought that large wounds such as were so often met with in civil practice were very amenable to treatment by primary suture.

Sir CHARTERS SYMONDS said that he had begun his war work in London, where men were arriving from the Aisne in a highly infected condition. In the case of severe fractures he kept the part in complete rest by putting it up in plaster-of-Paris. When the general inflammation had subsided in from four to seven days he removed the plaster. The wounds were generally found full of pus, but this seemed to act as an effective dressing. In the summer of 1916 he had employed first continuous and later intermittent irrigation. On his return to England he saw the cases from France, and noted the excellent results which followed primary suture. If the wounds were dry and free from pus it was possible to suture at once. He agreed that failure in the Carrel-Dakin method was due to defective technique. Asepsis should be perfect, and the wound should never be touched by the hands.

Mr. A. W. SHEEN said that in India they had received cases from Mesopotamia ten days after wounding. The wounds did not seem to be so infected as those in

France, probably on account of the dryness of the climate and non-cultivation of the soil. They were more like those seen during the South African War. He wished to see improvements in organisation as well as in treatment. The injured arrived at hospital in a very bad condition. In mines, works, factories, &c., there was little organisation for immediate treatment.

Surgeon-General A. **CORKER** said that he had been struck by the need for the universal teaching of first aid. In the army an endeavour was made to teach first aid to every officer and man. He had lately been on the committee of a school, and though all kinds of subjects were taught hygiene was not in the curriculum. He thought that first aid should be taught to the community at large.

EXHIBITION OF CASES.

Sarcoma of the Scapula.

Mr. **PHILIP TURNER** showed the case of Sarcoma of the Scapula in a man aged 46. The patient had first noticed and applied for treatment for weakness of the right arm. About the same time he had had tonsillitis. On examination a tumour of the scapula was found, together with enlarged axillary and supra-scapular glands. There was weakness and wasting of the muscles of the right arm. The right tonsil was much enlarged and ulcerated. Two or three weeks ago Mr. Turner thought there was new growth of the tonsil, but he now considered the condition was probably inflammatory, as the tonsil was smaller.

Fracture of Shaft of Left Humerus.

Mr. T. P. **LEGG** showed a case of Comminuted Fracture of the Shaft of the Left Humerus, with unusual nerve complications. The patient was a young man, aged 17, who was knocked down by a motor lorry and run over on Oct. 1st, 1919. On admission to hospital he was found to have a comminuted fracture of the left humerus, about the middle of the shaft, contusions of the left arm and thorax, and to be suffering from severe shock. He was blanched; the pulse was 130 per minute; there was left-sided abdominal pain and slight increase in the area of splenic dullness. These signs gradually abated, though the anæmia persisted for some time longer. The fracture was treated by extension in an abducted position on a "Thomas's ring splint." The signs of injury to the nerves were first observed about the twelfth to fifteenth day, inability to move the fingers being first noticed. On Oct. 24th the splint was removed, as union was taking place, and the arm placed between sandbags in a less abducted position. He was unable to flex the elbow and movements of the wrist-joint were absent. Massage was begun on Oct. 27th and electrical treatment on Nov. 3rd. On Oct. 17th the electrical reactions were tested. There was no reaction in the muscles supplied by the median or musculo-cutaneous nerves, nor in the muscles of the forearm supplied by the musculo-spiral. The reaction of the muscles supplied by the ulnar nerve was diminished. The deltoid reacted. Triceps was not tested. On Nov. 11th he was examined by Dr. S. A. K. Wilson, who reported "definite motor and sensory paresis (not an absolute paralysis of either) in the median, musculo-spiral, and musculo-cutaneous groups. The ulnar is relatively intact." On this date he was encouraged to begin to use his arm. On Dec. 9th the median nerve showed R.D. reaction, and the ulnar and musculo-spiral reacted to reduced faradic current. On the 29th the reactions were unchanged. He could flex the elbow to 90°. Treatment was still being continued.

SECTION OF SURGERY: SUBSECTION OF PROCTOLOGY.

DISCUSSION ON DIVERTICULITIS.

A MEETING of this section of the Royal Society of Medicine was held on Jan. 7th, Mr. J. P. **LOCKHART-MUMMERY**, the President, being in the chair, when Dr. W. H. **MAXWELL TELLING** read a paper on Diverticulitis, which appeared in full in THE LANCET of Jan. 10th.

Sir **JOHN BLAND-SUTTON** said that 30 years ago colic sacculi were mainly regarded as pathological curiosities, and our knowledge of their potentialities for evil was a direct result of surgical enterprise. His interest in them was aroused when trying to find an explanation of the phenomenon known as "spontaneous disappearance of abdominal tumours." This matter was discussed in the Royal Medico-Churnrgical Society in 1894 by Mr. Greig Smith, and increasing experience in abdominal surgery enabled Sir John Bland-Sutton to learn the part played by colic sacculi in producing localised swellings in the belly, which sometimes disappeared by expectant treatment, and the phrase "spontaneous disappearance of abdominal tumours" also disappeared from surgical phraseology when surgeons learned that acute and chronic diverticulitis, or sacculitis (names as ugly and cacophanous as appendicitis), mimicked many important lesions, especially acute and chronic appendicitis, cholecystitis, tumours of the stomach, sub-diaphragmatic abscess, perigastric abscess, splenic abscess, tubal infections, ovarian abscess, cancer of the uterus, and infected uterine fibroids. The extraordinary feature of sacculitis (or pericholitis) was its mimicry of cancer of the colon. In 1901 he excised the sigmoid flexure of a spinster aged 60 under the impression that it was cancerous. After the operation critical examination of the tumour proved that the supposed cancerous mass was a pericholic mass due to infection of a sacculus caused by a piece of straw. The patient recovered. This, with a case of epiploic abscess, was described before the Medico-Chirurgical Society of Nottingham in 1904, and full details were published in THE LANCET, 1903, ii., 1148. Since that date Sir John Bland-Sutton had seen and operated on many similar cases, and it was clear that in the past patients had submitted to colotomy and colostomy under the belief that they were suffering from colic cancer; subsequently the lump disappeared and the patients survived the operation many years, and at death there had been no evidence of tumour. This admitted of no doubt. Also cases were not uncommon in which a swelling is detected in connexion with the large gut, a diagnosis of cancer is made, and the patient is advised to submit to an operation, but he obstinately refuses, and in due course the swelling disappears, in spite of the gloomiest prognostications of physicians and surgeons of great experience and repute, and the patient lives to mock at his advisers. The disappearance of the mass was due to pus or the exudate finding a channel of escape. During the last ten years acute diverticulitis, especially in the lower abdomen, was recognised with the same certainty as acute and chronic appendicitis. The disquieting feature of these new things in abdominal surgery was the fact that as we grew older colic sacculi tended to increase in number, and as many as 200 had been counted on a colon. Thus diverticulitis was a newly discovered "bane of elders." As prevention was better than cure, it would be the duty of the family medical attendant to encourage men and women after middle life to have efficient sets of teeth and warn them against gobbling indigestible food or bolting hot and unpleasant morsels.

Dr. E. I. **SPRIGGS** referred to the work of Dr. Maxwell Telling and Dr. O. C. Gruner[1] in 1917, Dr. D. Roberts[2] in 1918, and Dr. J. W. Keefe[3] in 1917, on Diverticulitis, and said that the experience gained at Duff House supported the view that multiple diverticula could be recognised easily in X ray photographs of the colon, but such cases had not been found to be common. In the X ray examination of over a thousand alimentary canals diverticula of the large intestine had been seen six times. He had excluded between two and three hundred early cases from these figures, as they had not learned at that time the importance of taking photographs freely. The proportion of cases showing diverticula was doubtless understated by these figures, because in some cases the descending colon and sigmoid might not be completely filled at the times of examination; and if there were no bowel symptoms the opaque meal would not be repeated, nor would an opaque enema be given. Every effort was made, however, as a matter of routine, to see the descending colon and sigmoid when filled; and as the patient was staying in the same building as the X ray room this could usually be done. With good plates, when the little pouches were multiple and had reached the size of a small currant, they were easily seen. Diverticula in the early stages of their formation or diverticula which were few in number and were filled with fæces, or did not come into profile, might be missed; but if there were many of them, as there generally were, it was unlikely that none would fill with barium or show on the plate. As soon as they began to retain material longer than the bowel—that is to say, as soon as they were likely to be predisposed to inflammation—they were, if at all numerous, obvious; for the chain of opaque dots lying along the course of the empty bowel was characteristic. All of their cases showed retention of barium in the diverticula. Nine slides showing diverticula, from X ray photographs of six cases by Mr. Marxer, were then shown on the screen. Photographs were also exhibited on the walls. These six cases of unsuspected diverticula of the colon were all males, of ages varying from 53 to 71. One showed a single diverticulum on the plate; in the other five the diverticula were multiple and in three numerous. Two of them also showed one diverticulum in the terminal part of the ileum. In another there was a large single diverticulum, probably of a different nature, in the third part of the duodenum. The diverticula of the colon were thought to be simple extrusions of the bowel wall at weak places. It was to be noted that they occurred in those parts of the small and large intestine where the contraction of the muscle in the wall of the bowel might be supposed to be especially vigorous, with a corresponding increase of pressure in the lumen—namely, in the last few inches of the ileum and the latter part of the colon. One of the patients had suffered from severe constipation, four gave a history of moderate or intermittent constipation, and one had never been constipated. In four of the six there was no X ray evidence of delay in the bowel. In two there was such evidence, the opaque material not having passed through the colon in 72 hours. (The rate of passage of the buttermilk meal was quicker than that of some other opaque meals. With buttermilk 48–72 hours was regarded as a normal time.) In one case there was general hypertonus of the large bowel, and in one case hypertonus of the pelvic loop. The series was small, Dr. Spriggs said, but he brought it forward, firstly, to show how well diverticula could be recognised by the X rays; secondly, because it was an early series. Not one of these patients had any symptoms clearly attributable to the diverticula which were seen. He would, of course, in view of the risks they run, keep in touch with their medical advisers. In all the diverticulum-bearing area of the bowel was freely movable. The cases included two of chronic appendicitis (one of them with arterio-sclerosis), two of duodenal ulcer, one of gastric hypoacidity, and one of neurasthenia following a chronic infection. The last-mentioned patient had not been heard of recently. The other five recovered, and four of them were following active occupations.

Mr. W. MCADAM ECCLES showed a specimen of Part of a Pelvic Colon which had been divided longitudinally to show numerous diverticula and a marked narrowing of its lumen due to fibrous thickening of the wall. One diverticulum at its upper extremity, larger than the others, had a narrow neck and bulbous extremity, which appeared to pass into an appendix epiploica. Microscopically there was no evidence of malignancy, but an extreme degree of chronic inflammatory change. The diverticula were lined by normal mucous membrane. The specimen had been removed from a somewhat obese man, aged 74, who had been troubled for more than a year by chronic constipation and flatulence. The motions had never contained blood, but were always much flattened. A movable elongated tumour had been felt in the left iliac fossa and was regarded as carcinoma. The mass was excised and an end-to-end anastomosis was performed. No enlarged glands were found and recovery was complete. He thought that diverticula were congenital, that at birth there was a minute commencing protrusion. At the site of the diverticulum there was generally a circle of blood-vessels which ran up into the appendix epiploica, and therefore a possible hiatus. Diverticulitis occurred nearly always in men, not always in those subject to constipation. In many cases intestinal gas was present, the anal sphincter was active, and there was, in consequence, backward pressure, which was most felt in the pelvic colon. With regard to the differential diagnosis from cancer, it should be remembered that in diverticulitis hæmorrhage was very rare, whereas in carcinoma it was pretty constant.

Mr. G. GREY TURNER also took part in the discussion. His paper appears in full in the present issue of THE LANCET.

Mr. RUTHERFORD MORISON said that for centuries certain deformities of the blood-vessels and urinary bladder had been recognised and described as sacculi. Sacculated aneurysms, sacculi of the veins, and sacculated bladders had been, for all this time, acknowledged conditions, so that they had the hallmark of tradition. It was now known that all the hollow viscera might be similarly affected, but confusion had arisen because these protrusions had been described as diverticula. Sacculation of the colon had been described by anatomists as its normal condition, but this difficulty could be got over by regarding ordinary sacculation as normal, and acquired sacculation as pathological; this was easier when it was remembered that that part of the colon, the sigmoid loop, which was most generally affected by pathological sacculi, was at times almost devoid of the normal sacculation. The name was of great fundamental importance, because it involved a principle on which the progress of surgery depended. If each small part of the body was to be considered as the possessor of diseases peculiar and special to itself, then all real advance was impossible. The same pathology was applicable to all parts of the body, and in similarly constituted parts of it even the smaller details of disease were in essential qualifications alike. The signs of resistance of the tissues to their enemies (pathology) were relatively simple in their manifestations when compared with anatomical and physiological problems. Another reason for his objection to the term "diverticulitis" was that since Meckel's diverticulum was known the name had had a special significance. This anomaly was of congenital origin; all coats of the intestine entered into its composition; it had a special vascular supply of its own; it was single, and it was found at any age. These qualifications were common to all the ordinary intestinal diverticula, such as the vermiform appendix and those associated with pancreatic outgrowths. The sacculi were not of congenital origin but were acquired; their walls were thin and not composed of all the coats of the intestine; they had no special vascular supply; they were multiple, rounded in shape, and were almost limited to elderly people; they had been found in all of the hollow viscera and were of an importance not yet fully recognised. There was the same difference between a sacculus and a diverticulum as there was between an acquired and a congenital hernia. The only excuse for confounding them was that the pathology of both was the same. Both might harbour fæcal concretions or foreign bodies, and inflammation in them led to the same results—gangrene and perforation and general peritonitis, ulceration and sloughing with abscess formation, or inflammatory thickening and fibrosis, closely resembling a malignant growth of the bowel. The last condition was described, especially by American authors, as peri-diverticulitis; it was an important condition, but not special to the colon. It might be found in a portion of intestine reduced after strangulation; it had been found in the stomach (and called *linitis plastica*); it occurred in the skin (and was called keloid or pseudo-keloid); it occurred in the cæcum (and when due either to subacute sepsis or to tuberculosis was apt to be called hyperplastic tuberculosis). In all it was difficult to distinguish clinically and in some pathologically from cancer; in all it might be due to subacute sepsis, to tuberculosis, or to cancer.

Mr. HAMILTON DRUMMOND said that during a period of 18 months he had examined the intestines of all the bodies upon which post-mortem examination had been made in the Royal Victoria Infirmary, Newcastle-on-Tyne, about 500 in all, with a view of investigating the ætiology of pathological sacculi of the large intestine. During this period he had met with 22 specimens showing a marked condition of pathological sacculi, and these were from the bodies of people who had died from causes unconnected with the intestinal lesion; in many cases the sacculi were found in the pelvic colon only. It was an interesting and somewhat remarkable fact that in five of the cases in which sacculi were found in the colon there were also sacculi in other hollow viscera; in four cases there were sacculi in the small intestine, the opening appearing between the leaves of the mesentery; and in one case there were multiple sacculi in the bladder wall. This tendency to diffuse sacculation would seem to have an important bearing upon the causation of sacculi of the colon, as it suggested a more or less general weakness (perhaps congenital) of the non-striated muscle tissue throughout the body. Stress had been laid upon venous congestion as a predisposing cause, but many of the bodies examined when searching for cases of sacculi were those of elderly people with chronic heart disease and marked back pressure, and in none of these were sacculi found, a fact which did not support the venous congestion theory. Intestinal obstruction was another cause put forward in attempting to explain the development of sacculi, but in only two out of the 22 cases referred to could obstruction be said to be a factor, and these were typical ring cancers with well-marked sacculi above the growth. An examination of the specimens procured during the investigation demonstrated that the sacculi almost invariably took their origin between the mesocolic and one of the lateral bands, and frequently opened into the appendices epiploicæ. They were rarely found in the leaves of the mesentery or on the antemesenteric aspect of the gut. The appearance of pathological sacculi at these definite points in the bowel wall might be accounted for by the anatomical distribution of the vessels, for numerous microscopical sections pointed to the great frequency with which these sacculi pushed their way along the course of vessels. This fact had been pointed out many years ago by Klebs and Graser.

Mr. HAMILTON DRUMMOND then showed some drawings of pathological sacculi of the colon, with special reference to the position at which the sacculi made their appearance through the bowel wall. Microphotographs were shown illustrating how sacculi followed in the line of the vessels and tended to push their way towards the mesentery of the bowel; other microphotographs showed typical examples of how pathological sacculi open into the appendices epiploicæ; also the marked atrophy of the bowel wall in the actual herniated portion of the gut. All drawings and microphotographs were obtained from post-mortem room specimens, death being due to some other cause than the intestinal lesion.

Mr. GARNETT WRIGHT reported a case which was an example of colico-vesical fistula due to diverticulitis.

Mr. R. P. ROWLANDS said that during the last ten years he had operated upon eight cases of diverticulitis of the colon and one of the duodenum. Three of these operations were for peritonitis, due to perforation of a diverticulum.[4] The remaining five were for intestinal obstruction, the first two of which have already been published in THE LANCET.[5]

The first case was that of a very feeble, thin, anæmic lady of 60, who had suffered from constipation all her life. Mitral regurgitation was present, and there was almost complete intestinal obstruction, with œdema of the legs and ascites. Carcinoma of the sigmoid colon was suspected. The colon, from the splenic flexure almost to the rectum, was rigid, very thick and inflamed, and almost solid. She was too ill for resection. A short circuit was made with difficulty between the ileum and the lower part of the pelvic colon. For over a year she suffered from flatulent distension and looseness of the bowels, but secondary resection was declined. Gradually the diarrhœa ceased. Ten years later she was reported to have had no serious or acute affection of the bowels since the operation, though there was still flatulent distension and constipation.

In cases 2 and 3, men of 49 and 40, resection of 6 to 8 in. of the pelvic colon was performed for what appeared to be malignant disease. It was only after the operation in each case that an accurate diagnosis was made and the diverticula found after opening the bowel. Microscopic examination revealed the absence of carcinoma. In each case there was stenosis, with a definite tumour the size of a hen's egg. Both patients had rigors before the operation. They had remained in good health and had been able to work hard for nine years. In one case resection with immediate end-to-end union was adopted, and proved most satisfactory.

The fourth case was that of a lady of 60 who had had many attacks of pelvic peritonitis during 20 years. Appendicectomy had been performed elsewhere and a tumour then discovered in the pelvic colon. Three years ago several diverticula containing calculi were removed from the pelvic, iliac, and descending colon, and the tumour, localised to the anterior wall of the pelvic colon, was incised and found to contain two diverticula full of pus. These were excised and the bowel closed. The patient remained well for a year, but since then had had several milder attacks which had not been severe enough to call for further operation. The case illustrated the well-known difficulty of finding and removing all the diverticula, and pointed to cylindrical resection of the diseased segment of bowel as the operation of choice.

The fifth case was that of a man of 40, who had also suffered from many attacks of pelvic peritonitis supposed to be due to appendicitis. Four years before he was seen by Mr. Rowlands he had developed a colico-vesical fistula, and was told that he had inoperable cancer of the bowel. He was in a poor state of health and very depressed. The fistula was closed by laparotomy. It was between the middle of the pelvic colon and the left side of the bladder. The openings in the bladder and colon were closed and inverted. There were extensive adhesions in which were pockets of pus. The patient died a week later of pelvic peritonitis and pericarditis. No diverticula were found at the operation, but several were found from within the lumen of the bowel after death.

In such a late and difficult case the speaker thought it would be wise to start with a preliminary colostomy. This would immediately relieve the very troublesome cystitis and sepsis and make the subsequent operation easier and safer. Mr. Rowlands urged: (1) The importance of keeping diverticulitis of the colon in mind when operating for stricture of the colon. (2) That early resection with end-to-end union was the operation of choice. (3) That temporary colostomy was indicated in late or complicated cases, especially when distension could not be overcome before operation or a colico-vesical fistula existed. (4) That in some late cases a short circuit might be made, with subsequent resection if necessary. Preferably the transverse colon should be joined to the pelvic colon. The transverse colon was generally healthy and low in these obstructive cases. The subsequent resection was thus made easier and more satisfactory. Failing the transverse colon, the ileum or cæcum might be joined to the pelvic colon. (5) When temporary colostomy was performed it appeared wise to make the opening only a little above the stricture, so that it could be removed with the stricture at the second operation and a third operation thus avoided.

The discussion was adjourned until Wednesday, Jan. 14th, at 5.30 P.M.

SECTION OF SURGERY: SUBSECTION OF ORTHOPÆDICS.

EXHIBITION OF CASES.

A MEETING of this section of the Royal Society of Medicine was held on Jan. 6th, Mr. E. MUIRHEAD LITTLE, the President, being in the chair.

Coxa Vara.

Mr. R. C. ELMSLIE showed a case of coxa vara in a boy aged 9 months. There was a history of "cross-birth"; one leg was brought down (it was not known which), the left arm was fractured, the left leg was "black and blue." The child was brought to hospital in December on account of shortening of the left lower limb, which proved to be half an inch shorter than the right. The femur was bowed forwards and outwards in its upper part, and abduction of the limb was very limited. X ray examination showed that the femoral neck formed about a right angle with the shaft, and that the latter was convex externally immediately below the great trochanter. The epiphysis of the head and the neck of the femur were normal. The pathological anatomy differed from that of the form of coxa vara usually seen in young children, but the appearance might explain certain rare cases of coxa vara with a right-angled neck. The treatment indicated was osteotomy of the femur through the great trochanter, and abduction of the lower fragment into line with the upper.

[4] The Operations of Surgery, vol. ii., p. 437.

[5] THE LANCET, 1910, vol. i., p. 1194.

Osteitis Deformans.

Mr. E. **LAMING EVANS** showed three cases. The first was that of a woman aged 48, who came under his care at the Royal National Orthopædic Hospital in 1919. In 1910 she knocked her left leg against a form; a swelling formed, accompanied with slight aching pain. The swelling had got gradually larger since that date. In 1918 it suddenly increased in size, with exacerbation of pain. She was admitted into a general hospital in London. Wassermann's test proved negative on two occasions. After six weeks' observation and rest an exploratory incision was made into the tibia; since that date the pain had increased. There was now a uniform thickening of the upper two-thirds of the left tibia with a well-marked anterior curve; the left tibia was half an inch longer than the right. X ray examination showed a uniform absence of definition of cortical and cancellous bone in the upper third, together with obliteration of the medullary cavity. The middle third showed, in addition, a density suggesting cystic formation, with sequestra. For the last 15 months she had complained of pain in the back of the head and neck; the occipital region was tender, so that she avoided lying upon the back of the head. She thought the head had increased in size. The occipito-frontal circumference was 21 in. An X ray examination of the skull showed thickening of the occipital and parietal bones. He regarded this as a case of osteitis deformans, and thought it worth bringing to the notice of the section for the following reasons: (1) the definite traumatic origin; (2) the limitation, after nine years, to a single long bone; (3) the anterior curvature of the affected bone, whereas the usual curvature was antero-external; (4) the actual lengthening of the affected bone; (5) the interval of eight years from the commencement before involvement of any other region, and subsequent involvement of the occipito-parietal.

Mr. **ELMSLIE** agreed that the case was one of Paget's disease. He would accept all the phenomena as evidences of Paget's disease, but the appearance suggestive of a cavity with sequestrum raised a difficulty, as similar phenomena occurred in osteomyelitis. The skull changes, however, were sufficient to make the diagnosis certain.

Fracture of Right Carpal Scaphoid Bone.

Mr. Evans's second case was that of a man, aged 39, with fracture of the right carpal scaphoid bone. In 1917, whilst pushing down the handle of a motor, the engine back-fired, and, as the handle was not released, the patient received the thrust of the back-fire through the wrist-joint. He had only done a little light work since that date, and the disability would appear to be out of proportion to the physical signs. There were now slight swelling over the carpus, tenderness and pain over the scaphoid. The grip was fair except in certain positions of dorsal extension, when the hand became powerless. The power of dorsal extension was poor, and the extreme limits of movements in all directions were restricted. X ray examination showed a partially united fracture through the neck of the scaphoid, with arthritic changes between the scaphoid and os magnum. The cause of the fracture appeared to be of the nature of a crush between the down-thrust of the forearm and the up-thrust of the starting-handle. If at the time of the back-fire the handle was held with the hand deviated ulnawards, the head of the os magnum was directed towards the neck of the scaphoid, and, acting as a wedge upon its weakest point, produced a fracture in the region of the neck. If the hand was directed radialwards the head of the os magnum crushed upon the semilunar, and produced a subluxation or luxation.

Mr. C. **MAX PAGE** agreed that this injury was often in the nature of a crush fracture. He had recently had two cases in which the scaphoid had been broken as the result of a back-fire. He considered that when pain and disability persisted operative removal of the fragments was the proper course, and in his experience had given satisfactory results. After operation the wrist should be put up in a position of extension.

Dupuytren's Contraction.

Mr. Evans's third case was one of Dupuytren's Contraction affecting the ring finger of the right hand in a man aged 32. It appeared to be consecutive to a traumatic arthritis of the first interphalangeal joint, caused by the fall of the roof of a dug-out in 1915.

Mr. **PAGE** had observed the use of fibrolysin in a good number of cases both by local and by intramuscular injection. He had formed the opinion that the injection had no influence on existing scar tissue in these cases, and was of very doubtful value in the prevention of a recurrence of the deformity. He considered that after operation a return of the contracture could only be prevented by the wearing of an extension splint at night for a year or more.

PATHOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—A meeting of this society was held on Jan. 2nd and 3rd at the University of Manchester, where the first meeting was held on July 14th, 1906. The chair was taken by Professor H. R. Dean, and the society was hospitably entertained by the Pathological Society of Manchester.—Sir Kenneth Goadby (London) discussed a large number of cultural and microscopical examinations he had made of old war wounds. Bacteria, he said, might remain latent for an extraordinary long time; they did not necessarily cause any local tissue reaction, and most of the sporing anaerobes occurred in the vegetative phase.—Dr. J. H. Dible (Manchester), from a study of about 150 strains of intestinal streptococci, showed how on the average various properties (heat resistance, fermentations, &c.) were associated in such a way that it was possible to dissect up the very unsatisfactory group of the enterococcus and its allies along practically useful lines.—Dr. J. C. G. Ledingham showed that by inoculating rabbits with the excreta of lice infected with trench fever it was possible to obtain sera which would agglutinate emulsions of the Rickettsia.—Dr. A. H. Miller (Sheffield) demonstrated the nodular tubercle bacilli which he obtained by using a median containing sperm oil.—Professor Dean described a small epidemic of Flexner Y dysentery in the surgical wards of a children's hospital with several fatalities. One of the [illegible] infected its own family and one living next door on its return home.—Professor A. E. Boycott dealt with some of the difficulties in making single-cell cultures with the degree of certainty necessary in investigating the transmutation of bacteria. He also detailed experiments on the killing of tadpoles by heat, and contrasted the results with those of similar trials with bacteria.—Dr. J. Holker (Manchester) exhibited a very convenient apparatus for measuring the opacity of liquids, and gave an account of a philosophical study of what happens when antigen serum and salt solution are mixed in the Wassermann reaction.—Dr. J. Cruickshank (Dumfries) described his experience with the gold sol test of the cerebro-spinal fluid; he had found it of great value in the diagnosis of general paralysis. He also detailed a number of curious observations showing that solutions of lecithin in ether, &c., had a special capacity for extracting dyes and some inorganic salts from watery solutions which was not shared by lipoids in general.—Dr. A. G. Gibson (Oxford) found that a positive Wassermann reaction might appear at very variable times after a provocative dose in persons who were suspected of being cured.—In an original communication Dr. C. Powell White (Manchester) discussed the application of statistical methods of correlation to the interpretation of urine analysis, and made out a good case for the utility of the method in discovering the actual combinations of acids and bases secreted by the kidney.—Professor E. Emrys-Roberts (Cardiff) detailed a number of cases of infected wounds in which very good results had followed the exhibition of normal horse serum subcutaneously.—Professor Dean exhibited a case of cancer, probably of a bronchus, with a large number of cystic metastases.—Dr. Clara Stewart (Leeds) and Dr. A. Leitch (London) both dealt with the migration or metastasis of adenomyomatous uterine tumours; and Dr. W. E. Hume and Dr. A. F. B. Shaw (Newcastle) gave a full account of a fatal case of splenomegalic polycythæmia, in which opportunities for post-mortem examination seldom occur.—Professor M. J. Stewart (Leeds) put in a plea for the more extended use of the polarising microscope in pathological histology, and showed how useful it may be for finding sutures and ligatures in tissues.—There were a large number of interesting exhibits.

Reviews and Notices of Books.

WAR DISEASES AND PENSIONS.

By R. M. WILSON, M.B., Ch.B., Temporary Captain, R.A.M.C.; and W. M. T. WILSON, M.B., Ch.B., late Temporary Captain, R.A.M.C. With a chapter on the Diagnosis of Malaria by Major ERNEST BLACK. London: Oxford University Press. 1919. Pp. 71. 3*s.* 6*d.*

THIS small manual is an attempt to guide the footsteps of pensions boards along right channels, and with this object in view is didactic in style and expression. Its main purpose is to combat the snare of symptomatic diagnosis, especially that of "D.A.H.," a term which is still, we fear, loosely applied without any sufficient attempt to discover the basis of the symptom. The pensioner is in consequence incorrectly labelled as a "heart case" and becomes a perpetual worry to the examining officer as well as to himself. At one board he may complain chiefly of his heart, at another of his aching limbs, at a third of his indigestion or headache, and so on. The authors of the manual believe that at least half a million such misfits in diagnosis are going about the country.

Having given a concise description of the nature of "D.A.H.," the writers go on to suggest the relation between various toxic states and this condition, showing how the symptoms vary: (*a*) with the degree of infection and (*b*) with the amount of effort or excitement called for. Tremors and hyperidrosis are, they find, strongly suggestive of trench fever, and the usual symptoms of neurasthenia, commonly laid to the charge of "shell-shock" alone, are here ascribed to an initial toxic origin. The authors' dogmatism on this point will doubtless bring into the field those who hold a contrary view, who may begin by throwing a doubt on whether trench fever is really as common in this country as the authors suggest. There can be no question, however, that cases of chronic trench fever are often carelessly diagnosed as tuberculosis; this is an everyday experience of pensions boards.

The frequency of a systolic apical murmur and a displacement of the apex beat outwards to the nipple line in "D.A.H." cases are cited, and attention is drawn to the researches at Mount Vernon Hospital, which showed that there is no true dilatation in these cases. The differential diagnosis of auricular fibrillation and extra-systoles by means of the exercise test is described, but the authors are inclined to discount the value of this test as a means of estimating the poisoning of the cardiac nervous system, and prefer to substitute the effect of a long and deep inspiration. Their conclusion is noteworthy:—"No man should be pensioned for D.A.H. Pensions should be awarded for malaria, trench fever, dysentery, and so on—that is to say, for the fundamental infections which cause D.A.H."

The clinical features of trench fever, malaria, and dysentery are concisely recorded, and a valuable chapter by Major Black is devoted to the treatment of malaria. In most cases of malaria sèvere dyspnœa on exertion is not a common feature, and the presence of an added dysenteric infection should be excluded by the examination of the stools for the *Entamœba histolytica*. A few useful hints on the assessment of the degree of disability are added.

The authors of this volume are to be congratulated on the production of a timely and helpful book, which will afford aid to those engaged on pensions boards and to the general practitioner who is called upon to deal with the soldier invalided on account of one or other of the diseases of war.

A HANDBOOK OF GYNÆCOLOGY.

By BETHEL SOLOMONS, B.A., M.D. Dub., F.R.C.P. Irel., Gynæcologist, Mercer's Hospital, Dublin, &c. London: Baillière, Tindall, and Cox. 1919. Pp. 12+236. 10*s.* 6*d.*

THIS little book consists mainly of notes of the author's lectures. He has written it because he believes that the student requires a small book to help him in his practical work. The book contains a good deal of useful information, but we do not think that the author has been happy in the selection of his material. It seems a pity when so little is known about menstruation to mention the latest theory, for which it is admitted there is not much experimental proof, and to leave out others, many of which are much more probable. Dr. Solomons calls attention to the fact that the nomenclature of certain tumours of the tube is very unsatisfactory. If this is so, then surely in a book of this scope it would have been wiser to omit the list of such tumours, which is given without a word of explanation. The recommendation to give every woman a vaginal douche before a pelvic examination cannot be intended for ordinary practice; it is unnecessary and, indeed, is impracticable in the majority of cases in private practice. The fact that the membrane in cases of imperforate vagina is not the hymen is not called attention to. Cysts of Gärtner's (sic) ducts are said to be single, when not infrequently cysts of Gartner's ducts are multiple. The recommendation to remove a fibroid polypus with a pair of clip forceps in the majority of cases would be quite impracticable; nor can we agree that in the removal of a large tumour of this kind the cervix should be slit up; why cut the patient when it is quite easy to cut the tumour? The author exaggerates, in our opinion, the danger of using a repositor in treating cases of inversion; when used properly, this instrument has been proved in considerable numbers of cases not to be at all dangerous.

NEOPLASTIC DISEASES.

A Text-book on Tumours. By JAMES EWING, A.M., M.D., Sc.D., Professor of Pathology at Cornell University Medical College, New York City. London and Philadelphia: W. B. Saunders Company. 1919. Pp. 1027. £2 2*s.*

IT is usually taught that neoplasms may be classified according to their morphological and biological characters, with little or no reference to the organs or parts of the body in which they grow. All carcinomata are regarded as fundamentally identical, whether they occur in the tongue, the rectum, or the breast; and the solution of the "cancer problem" as a whole is sought for rather than the ætiology of any particular form of tumour. Professor Ewing, however, believes that new growths are susceptible of a much finer analysis, and in this excellent work his aim has been to analyse and differentiate the various types of neoplasms, to enumerate and contrast the more striking clinical features characteristic of different tumours, and to consider the ætiology of individuals rather than the type.

The book is divided into two main parts, the first of which treats of general oncology, and includes a good historical survey, and chapters on general pathology, malignancy, metastasis, the chemistry of tumours, ætiology, and experimental research. The second part, which is by far the larger, deals with special oncology. Here, while the simpler connective-tissue tumours are considered separately, and there are special chapters on endotheliomata, sarcomata, and carcinomata, the author, true to his conception of malignant disease, takes the various organs in turn, and discusses in detail the neoplasms which may be found in them. The final chapter, on Teratology, gives a résumé of this branch of the subject, and, though brief, is adequate, since the commoner teratomata are described elsewhere according to the organs in which they occur. There is a very complete bibliography, the references being conveniently grouped according to chapters at the end of the book, with page numbers in heavy type; and the index leaves nothing to be desired.

There are 479 illustrations, nearly all from photographs. The majority of these are successful, but the details of some of the microscopical preparations would have been more satisfactorily shown by drawings. Some of the figures are, we think, likely to confuse the student. It is surely unfortunate that the first illustration in the chapter on Fibroma should be of a benign pigmented fibro-epithelial wart which bears no resemblance at all to a fibroma; and the student who has been taught to consider Paget's disease of the breast as a chronic inflammation of the nipple ssociated with a mammary cancer may well rub his yes to find this condition illustrated by lesions of the kin of the buttock. It is, however, impossible to rovide at one and the same time for the beginner and he expert, and though the former may not appreciate, he latter will be grateful for many of the rare and nteresting conditions which are figured.

Professor Ewing has produced a book which will, we hink, be recognised as the standard work of reference n this subject in the English language for many years o come. His knowledge of the literature is immense, nd he has drawn upon it freely, so that, although the ook is based on his own experience, practically every age contains references to the work of others. It is emarkable that such a stamp of individuality should ave been retained in so broad and catholic a survey of he subject. The author holds definite views on many isputed points, and, though some may differ from them, ll will acknowledge the fairness with which they are resented. The chapter on Endotheliomata illustrates his as well as any other. The history and present osition of the controversy which has ranged over these ifficult tumours are admirably set forth; and though rofessor Ewing acknowledges himself a believer in the ndothelial origin of a wide variety of tumours, he akes no attempt to belittle the difficulties of proving t. He holds that it is possible to recognise the eoplastic endothelial cell, but on p. 300 this cell is escribed as possessing "a small, pale, vesicular nucleus ith minute multiple nucleoli," while on p. 302 it is said o have a "pale nucleus devoid of nucleoli."

The importance of chronic irritation in the ætiology f malignant disease is now universally recognised, and rofessor Ewing rightly lays great stress on it. We hould be inclined to join issue with him, however, on he question whether a single trauma, as distinct from ong-continued irritation, can initiate the malignant rocess, and we think his views as to the occurrence f a definite "pre-cancerous stage" will be exposed to n even more critical examination. So far as we know, here are no histological tests by which we can ecognise the actual development of malignant properties n an epithelial cell, and the early stages in the formaion of a sarcoma are, if possible, even more obscure. he pathologist may find it difficult enough to deterine from a section whether he is dealing with a alignant process or not; if, in addition, he has to ultivate the gift of prophecy his task will become an npossibility or be reduced to a mere pious expression f opinion.

Such a book as this will prove invaluable to the dvanced worker, but its very merits render it less seful to the student. The philosophic outlook and ck of dogmatism are, we regret to think, properties hich will militate against its success as a mere textook; but we have no doubt that it will achieve a much igher position in medical literature, and we cordially ongratulate Professor Ewing on the success which has ttended his labours.

A RACHIANESTHÉSIE GÉNÉRALE.

By Professor THOMAS JONNESCO. Paris: Masson et Cie. 1919. Pp. 182. 4 francs.

Professor Jonnesco has condensed in the present mall volume his experiences of 11 years of work on pinal anæsthesia. He was engaged upon a big work hen the war separated him from his manuscript, his tatistics, and his papers generally, the fate of all of which n Bucharest is still doubtful. Professor Jonnesco is, of ourse, a whole-hearted advocate of spinal anæsthesia, elieving it to be the best available method for procuring næsthesia during operation on any part of the body. Iis method consists in the injection of stovaine and trychnine into the subarachnoid space at one or more f four different sites according to the seat of operation. hese sites he calls the medio-cervical, the upper orsal, dorso-lumbar, and lumbar, and their position is ufficiently indicated by their names. The dosage is aried according to the height in the spinal column at hich the injection is made and according to the condiion of the patient. Failure to observe these conditions ith sufficient care accounts, according to the author, r such failures or fatalities as have occurred.

The high punctures have been made on more than 1000 occasions by the author and colleagues and pupils in Roumania. In his own practice there has been no fatality. The alterations in respiration which occur after high punctures are important and are described in detail; they differ according to whether, before injection, the patient is breathing by abdomen or thorax alone, or by both. The paralysis of breathing that occurs is due to effects on the cervical nerve-roots and not on the bulbar centres, and is of so short a duration that, treated by artificial respiration, it leads to no harm. The anæsthesia produced is a true analgesia—an obliteration of all pain sensations, but not of those of touch and of heat and cold. The author writes with enthusiasm, and his results, as stated, bear out his claims, but when he draws a comparison between inhalation anæsthesia and his own method it is obvious that the best results of the former method have not been at his disposal to compare with the best performance of the latter.

A COMPLETE SYSTEM OF NURSING.

By A. MILLICENT ASHDOWN, Examiner in Nurses' Practical Work to Guy's Hospital. London: J. M. Dent and Sons, Ltd. 1919. Pp. 746. 12s. 6d.

THIS comprehensive text-book was originally the work of Miss Honnor Morton, but it was entirely rewritten and illustrations added by Miss Ashdown in 1917. The latter has made it her object to produce a book which deals with every branch of her profession without going into such detail as would have made the volume unwieldy. A short account of the nature and treatment of a large number of diseases is given, though the author is emphatic in stating that it is not her intention to encourage nurses to act on their own responsibility "except under circumstances of extreme urgency." The text is well illustrated, for the most part with original pictures, which demonstrate methods of bandaging and bed-making, instruments and their application, and various typical temperature charts. The text has been carefully compiled and has a good index. Among the additions made in the revised 1919 edition is an account of the treatment of burns with wax.

The volume is brought thoroughly up to date, and will be widely read, not only by practising nurses and probationers, but also by health visitors and those numerous V.A.D.'s who are anxious to make use of their war experience in wider fields of service.

JOURNALS.

Parasitology. Edited by GEORGE H. F. NUTTALL, F.R.S., assisted by EDWARD HINDLE, M.A., Ph.D. Vol. XI., Nos. 3 and 4, October, 1919. Cambridge University Press. Price 25*s.* net, yearly subs. £1 15*s.*—Intestinal Protozoa Found During Acute Intestinal Conditions amongst Members of the Egyptian Expeditionary Force, 1916–1917, by F. W. O'Connor, comprises observations made by the author when employed as protozoologist to the field laboratories during the latter part of 1916 and 1917. A record is given of the various species of protozoa found in the stools of both white and Indian troops and members of the Egyptian Labour Corps suffering from dysenteric or diarrhœal conditions, and also of the parasites found in the stools of Egyptians not complaining of illness. *Entamœba coli* was the most prevalent, followed by *E. histolytica* and *E. nana.* Among flagellates *Lamblia intestinalis*, *Chilomastix mesnili*, *Trichomonas hominis*, and *Tricercomonas* are recorded, and of especial interest are nine cases of *Isospora hominis.* Two very heavy infections of this coccidium were observed, and attempts were made to infect puppies but without success. — The Genus *Lernæopoda*, including a Description of *L. mustelicola* n.sp., Remarks on *L. galei*, and Further Observations on *L. scyllicola*, by W. Harold Leigh-Sharpe, is an account of the four commonest species of *Lernæopoda* occurring parasitic on the fishes of British waters.—A Practical Hot-air Disinfector, by Harold Orr, contains a description, together with diagrams, of a very simple form of hot-air chamber which has been used on a large scale for disinfecting the clothing of troops. As the louse and the nit are both destroyed by ten minutes' exposure to a dry heat of 55° C., it is obvious that this method of killing them is preferable to the use of sulphur dioxide or steam. For practical purposes the material for disinfestation was exposed to a temperature of 75° C. for 20 minutes, and the chamber described affords a ready means of obtaining these conditions in the field.—Hermaphroditism and other Abnormalities in *Pediculus humanus*, by D. Keilin and G. H. F. Nuttall, contains an extremely interesting account of the results of crossing the human body-louse with the head-louse. Under certain conditions these crosses result in the production of a large number of hermaphrodites in the offspring, and the present article comprises a description, together with numerous illustrations, of a very large number of these forms. Results of experiments are also given in support of the specific identity of "*P. capitis*" and "*P. corporis*." Apart from the fact that they are mutually fertile, when *capitis* are bred in pill-boxes on the body they gradually acquire all the morphological characters of *corporis*. *Capitis* and *corporis*, therefore, constitute merely two races of one species, *Pediculus humanus*.—The Systematic Position, Synonymy, and Iconography of *Pediculus humanus* and *Phthirius pubis*, by G. H. F. Nuttall, also includes a useful chapter on the systematic position of the *Anoplura* and definitions of its suborders.—Further Observations on the Habits and Parasites of Common Flies, by G. S. Graham-Smith, contains many useful additions to our knowledge of flies and their parasites. The first part of the paper is devoted to an account of the influence of weather on flies, from which it appears that the curve recording the number of flies caught corresponds with the curve for the maximum temperature recorded in the sun. The appearance of flies early in the season does not necessarily indicate a great abundance in the latter part of the season. The cleansing habits of flies are illustrated by a series of excellent photographs of *Sarcophaga carnaria*. Empusa disease is found to infect species other than house-flies, in captivity *S. carnaria* being especially susceptible. In addition, specimens of *C. erythrocephala*, *L. cæsar*, *H. dentipes*, *F. canicularis*, *A. radicum*, *M. corvina*, and *S. stercoraria* have been found suffering from the disease. Certain Gamasid mites destroy both fly eggs and young larvæ, whilst various beetles destroy large numbers of puparia, but the most important enemies are the *Hymenoptera parasitica*. Examples of the five most important families—namely, the Cynipidæ, Proctotrypidæ, Ichneumonidæ, Chalcididæ, and Braconidæ—are described and figured. Further, very interesting experiments and observations are included on the life-cycle of *Melittobia acasta* and of *Alysia manducator*.—On the Life-History of *Ascaris lumbricoides*, L., by F. H. Stewart, constitutes the fourth part of the author's observations on this parasite. The present article is an account of three experiments with *Ascaris suilla* and a description of the larvæ that were obtained by feeding the "ripe" eggs to sucking-pigs.—The Incubation Period of the Eggs of *Hæmatopinus asini*, by A. Bacot and L. Linzell, comprises an account of experiments on the length of time taken to hatch the eggs of the common horse-louse. The results show that eggs may hatch up to 34 days after being laid, but the majority hatch after about 18 days.—Observations on the Biology of the Ixodidæ, by G. H. F. Nuttall, deals with the behaviour of the sexes in *Amblyomma hebræum*, *Hyalomma ægyptium*, and *Rhipicephalus bursa* when upon the host. The behaviour differs in these three ticks, for in the case of the first-named species the females seek the males, whilst in the other two the males seek the females.—On Two New Species of the Cestode Genus *Oochoristica* from Lizards, by H. A. Baylis, contains a description of two new species of tapeworms, and a comparison of the two genera *Oochoristica* and *Linstowia*.—Tsetse Flies and Trypanosomiasis, by H. Lyndurst Duke, is a most important article on "some questions suggested by the later history of the sleeping sickness epidemic in Uganda Protectorate." The writer, who has had many years' experience of sleeping sickness in Uganda, supports the hypothesis that there are two types of human trypanosomiasis in that region—one chronic, still widespread throughout the wild game, the other invariably fatal. The latter strain is supposed to be transmitted only by mechanical means, such as when the same fly bites two or more persons with very short intervals between. In the present place it is not possible to do full justice to the author's views, but the main issue of the article is to call attention to the question raised by the outcome of the preventive measure with a view to determining future policy. The obvious interpretation seems to be that reconstructive efforts might be begun in Uganda, on the assumption that an epidemic of sleeping sickness is impossible unless there is a sufficiently broad contact between fly and population to render possible the development of a virulent *mechanically transmitted* strain.—On the Life-History and Larval Anatomy of *Melinda cognata*, Meigen (*Diptera calliphorinæ*), Parasitic in the Snail *Helicella* (*Heliomanes*) *virgata*, Da Costa, with an Account of the other Diptera Living upon Molluscs, by D. Keilin, consists of two parts. In the first is given a complete account of the life-history and early stages of a common species of fly which the author found at Cambridge living as parasites on a common snail, whilst the second part is a review of all observations made hitherto on the life-history of different flies feeding upon living or dead molluscs. With regard to *Melinda cognata*, the female lays two or three eggs in the mantle cavity of each snail. The larva that emerges from the egg bores into the kidney and gradually destroys the renal epithelium, while later it devours the kidney and liver, thus killing the snail, and the final stage of development is completed in the decomposing liquid mass formed in the shell by the putrefying remains of its host. Finally, the larva pupates in the earth, the adult emerging about a fortnight later. A large number of species of flies have been recorded from molluscs, but in practically every case the observations are so incomplete as to be of little value. In an appendix the author mentions an interesting observation by M. E. Séguy, showing that the larvæ of *Musca domestica* will attack snails and complete their development as parasites. From 50 snails collected in the middle of January at Rambouillet nine yielded larvæ of the house-fly.—The Anatomy of the Head and Mouth Parts of *Psylla mali*, the Apple Sucker, with Some Remarks on the Function of the Labium, by A. J. Grove, in addition to providing anatomical details of an important agricultural parasite, contains some observations on the method by which the operations of piercing and sucking are performed in the Hemiptera.

The Journal of Pathology and Bacteriology was founded by Sir G. Sims Woodhead in 1893 and for 27 years has been the only British periodical entirely devoted to pathology. The first 11 volumes were published in Edinburgh and had already done much to encourage the study of pathology in this country when the Pathological Society of Great Britain and Ireland was founded in 1906. It was felt by the promoters of the society that an association with some periodical was most desirable, but there were obvious objections to a young society burdening itself with the responsibility of a substantial journal whose financial position was not completely secure. Ultimately in 1907 the journal was purchased from Professor Woodhead and Mr. Pentland by a company of 13 proprietors, members of the Pathological Society, who have been responsible for its conduct till the present year, and at the same time the society adopted the journal as its official organ. Under the skilful guidance of Professor Woodhead and Professor James Ritchie 11 more volumes have been issued and the progress of the paper has been so satisfactory that at the last meeting of the Pathological Society the proprietors were able to pay off the original purchase money and hand over the journal to the society with an adequate working balance. The *Journal of Pathology and Bacteriology* thus becomes the property of the Pathological Society of Great Britain and Ireland, and its founder may well be congratulated on the success of his public-spirited efforts, continued now for nearly 30 years, to promote the progress of pathology.

THE LANCET.

LONDON: SATURDAY, JANUARY 17, 1920.

The Epidemiology of Accidents.

THE efforts which are being made through an organised "safety-first" campaign in this country, and through the activities of the National Safety Council in America, to reduce the prevalence of accidents deserve every support. There can be no doubt as to the value of the work; in the annual report of the Chief Inspector of Factories for 1918 the claim is made that the establishment of accident committees in factories may reduce industrial accidents by 50 per cent.; and in the United States of America, in a two weeks' "drive" in October, 1918, on the railroads of the North-Western region, there was a casualty reduction of 67 per cent., while 42 out of the 63 railroads concerned came through the two weeks without a single serious accident. There is, however, a tendency to concentrate effort on reducing accident risk without pausing to consider whether other influences may not also be concerned in accident causation; yet a careful study of cause should always precede action, for where the cause is not known the effect cannot be deduced. Two elements contribute to the occurrence of nearly every accident: (1) the risk of injury, and (2) the individuality of the person injured. A motor-car travelling along a street represents risk of injury to a foot passenger; but it is the temporary folly of the foot passenger which causes him to step off the kerb in front of the car.

Statistics of industrial accidents throw considerable light on the importance of this second element in accident causation; and their investigation suggests that accident prevention, an important branch of the science of preventive surgery, is closely akin to preventive medicine. The idea that an accident is, as the word suggests, a chance occurrence, is found to be no more true than for an attack of typhoid, influenza, or tuberculosis. Each industry has its own accident-rate associated with the risk of that form of employment; but this rate is not a chance one; it is as regular from year to year as the occurrence of tuberculosis or cancer, and steadily rises with advancing age; it is, in fact, a statistical entity obeying epidemiological laws. The diagram, which we reproduce below, is a typical one for industrial groups. Not only is the total number of accidents thus regular, but the numbers due to special types of risk (e.g., machinery in motion, falling bodies, persons falling) and affecting special parts of the body (e.g., loss of whole or part of arm or leg) are similarly regular year by year. Accidents appear to be dependent on the personality of the persons injured and to represent reaction to environment. Influences which affect health also affect the incidence of accidents; thus, hours of work, illumination, temperature, and ventilation affect activity and fatigue; they have also been shown by VERNON[1] to influence the prevalence of accidents. Nor does the likeness between the occurrence of accidents and illness stop here; for, according to GREENWOOD,[2] some persons have a tendency to sustain accidents, just as in the field of medicine some persons have a predisposition to succumb to tuberculosis or other infectious disease. Apart from any innate predisposition, there are times when any person is more liable to accidents than at others; just as most people are aware of attacks of losing things, and when one thing is lost expect to lose two more before the attack is over.

Temporary or permanent individual reaction to environment appears to be as important an influence in the causation of accidents as in the occurrence of disease; and the safety-first campaign must direct its attention to this question if it is to meet with the success it desires. BELLHOUSE, after stating[3] that in factories in 1918 twice as many non-machinery accidents—i.e., accidents due directly and obviously to human mistakes—occurred as machinery accidents, considers that not less than 65 per cent. of the latter may be attributed largely to such causes as negligence, carelessness, want of thought, and, perhaps more than all, to lack of proper appreciation of danger. The maintenance of safety, like the maintenance of health, consists of a rope with health at the one end and risk at the other. A person in sound health will resist either the risk of normal microbic invasion, or, aided by quick special sense reaction, risk of accident occurrence. Lower the health resistance and the pull of risk will win the tug of war. Similarly, of course, increasing the risk, as by mass infection or increased

potency on the one hand, or by an earthquake or explosion on the other, will produce the same effect; but increase of risk is abnormal compared with lowered health resistance. Just as education in personal health is to-day the best means for improving national health, so, in a "safety-first" campaign, the aid of the individual and his education as to the existence of risk, with the way to avoid it, are the matters of primary importance to be considered. In matters neither of sickness nor of accidents can all element of risk be removed; but by improving health and alertness, rather than by fencing the public with protective guards, the influence of risk can be resisted.

◆

Lessons from the Flexner Bacillus.

It is now universally agreed that the microbes which cause bacillary dysentery are *B. dysenteriæ* Shiga and *B. dysenteriæ* Flexner. These organisms form a natural genus having the following characteristics: "They are short rods, destitute of flagella and non-motile, forming no spores, not liquefying gelatin, negative to Gram's stain, and fermenting glucose and sometimes other sugars and alcohols without formation of gas."[1] The bacteriological diagnosis of the organisms depends chiefly upon their biochemical and serological reactions. Shiga's bacillus reacts with a smooth regularity to well-defined tests and its identification therefore presents no great difficulty. It is distinguished from Flexner's bacillus by its inability to ferment mannite, by its constant failure to produce indol in peptone water, and by sharp differences in its agglutinating properties. It also differs from the Flexner organisms in its high toxicity to man and animals. For these reasons most workers now regard Shiga's bacillus as a distinct and separate species, of which we have, so far, only one serological type. The Flexner bacillus presents greater difficulties. By means of its variable sugar reactions and its agglutinogenic powers it can be separated into several distinct strains.

The classification of the Flexner bacilli, which has up to now formed the usual working basis for bacteriological laboratories, and which is found in current text-books, is that put forward by Hiss in 1904. This observer proposed to separate the organisms proved to have a causal relationship to bacillary dysentery, and differing from Shiga's bacillus in fermenting mannite, into three groups—the Flexner, the Y, and the Strong. The first differs from the second in fermenting maltose; the organism found by Major R. P. Strong, U.S.M.C., ferments saccharose as well as maltose. Each group is further distinguishable by agglutination reactions. This classification is now known to be imperfect. In the first place the sugar reactions of these bacilli are very variable, and are therefore unreliable as a basis of classification; in the second the antigenic structure, and consequently the agglutinations, of the organisms are much more complex than is indicated in Hiss's terminology. Kruse, who has contributed so largely to our knowledge of this subject, published in 1907 a more complete classification of the mannite-fermenting dysentery bacilli, in which he divided the group into half a dozen serologically distinct races. These were labelled A, B, C, &c. His work was confirmed by other bacteriologists in Germany, but, unfortunately, when the European war broke out, there was no collection of Kruse's strains in this country. The diagnostic work in dysentery in the war suffered as a consequence owing to the small range of agglutinable emulsions and agglutinating sera provided. Professor F. W. Andrewes and Dr. A. C. Inman have now published a study of the dysentery bacillus in which they show how five strains have been delimited by serological methods. They have put the absorption of agglutinin technique on a quantitative basis and have used it to indicate the antigenic composition of the different races, which is represented by ingenious coloured diagrams. The provision of agglutinating serums corresponding to these organisms will make bacteriological diagnosis of dysentery much more satisfactory.

A note on the general utility, apart from diagnostic purposes, of the separation of an organism into strains by means of agglutinins may not be inappropriate. From the point of view of infection and immunity the work of Dr. W. J. Tulloch on *B. tetani* and of Miss M. Robertson on *Vibrion septique* has a direct bearing on the subject. These workers have shown that the anaerobic bacilli mentioned may each be separated into several serologically independent strains. Each organism excretes a soluble toxin to which a corresponding antiserum can be prepared. Now, a monovalent serum—that is, a serum prepared by immunising an animal against the toxin of a single race of one of these bacilli—is able to neutralise the toxin of each and every race. There is thus no advantage in using either a monovalent or polyvalent serum. It follows that, although the bacillary protoplasm of *Vibrion septique* may possess variable antigenic properties, the toxins produced by all the strains are identical. In tetanus and gas gangrene the pathological changes are produced by toxins. The agglutinogenic powers of the organisms do not, therefore, appear to be of great practical importance.

◆

Infectious Disease and the Public View.

The daily press appears to have become hypersensitive towards the incursions of infectious disease. So far as this represents a balanced endeavour to stimulate measures for the control of preventable infectious disease, and to educate the community in the need for such prevention, the public and the medical profession have reason to be sincerely thankful. But more than occasionally the doctor feels that the criticisms of his endeavours, which the lay reader is offered, are the outcome of an imperfect acquaintance with things as they happen. During the past ew weeks there has been a rise in the prevalence of scarlet fever and of diphtheria throughout the country, a rise which has been brought nto particular prominence in London, where the situation has been aggravated by the ailure of the War Office to restore to the Metropolitan Asylums Board certain fever hospitals ent for war purposes. For this the Ministry of Health has been taken to task, and a statement has been demanded from it as to its activities in searching out the origin of the epidemic, and as to whether it has traced the infection to any carriers or to a milk-supply. Certainly there is a substratum of value underlying this stricture, in that t is the duty of public health authorities, and in a more general sense of the Ministry of Health, to search for the origins of outbreaks of infectious disease. But the particular comment is ill-directed. In view of the multitude of carriers of diphtheria and scarlet fever constantly in London streets, and the universality of the rise in the prevalence of these diseases in the various districts, t is futile to talk of tracing the origin of this wave of disease back to particular carriers. A few moments spent in comparing the type of incidence of a milk-borne epidemic with that of the present outbreak of scarlet fever in London, would show at once not merely the unlikelihood of milk being its source, but also, it is to be hoped, the unwisdom of causing unnecessary perturbation to many a parent.

---

[1] A Study of the Serological Races of the Flexner Group of Dysentery Bacilli. By Professor F. W. Andrewes, F.R.S., and Dr. A. C. Inman. Medical Research Committee Special Report Series No. 42.

We set this out merely as an illustration of the attitude towards these subjects in some quarters. What is the reason for the attitude revealed? The fact, we imagine, is that while engaged very properly in educating the general public to take an ntelligent interest in its communal health, the average editor is himself undergoing education as a layman in the science of preventive medicine. That education seems at present in some instances to be passing, as regards preventive medicine, through the "bottle-of-medicine" stage which typified much of the therapy of the past: if the community s being plagued by infectious disease, then give t for each such outbreak an appropriate bottle of medicine, labelled "carrier traced" or "milk-supply nfected," or what not. This is not the progressive spirit which the public has a right to expect in the advice which it receives. It is necessary to appreciate the fact that there is much in the ncidence of infectious disease still unexplored, and incapable at present of control. The statement published by the Ministry of Health on Dec. 19th ast with reference to the London outbreak of scarlet fever is the kind of counsel that is really useful. In that statement it is pointed out that the present prevalence of scarlet fever s probably connected with the cyclic recurrence of the disease, and that: "The periodic or quasi-periodic appearance of epidemics is probably due to the occurrence of a cycle in the life-history of the unknown causative organism, and the increase of the non-immune population—causes which are beyond the sphere of administrative control." It does not follow that they will always continue to be beyond administrative control. Every effort should be made steadily to shed light on obscure points in the natural history of infectious diseases, and the encouragement of steady search for knowledge is welcome from whatever source, and immeasurably welcome when it comes from influential quarters. But an irrational demand for the immediate cessation of a particular outbreak, coupled with the implicit demand for somebody's head on a charger if the feat is not accomplished, serves no one.

The medical correspondents of lay papers have a grave responsibility in advising their chiefs as to the facts of infectious disease, as to the possibilities of prevention and of control, and as to the exercise of a proper sense of perspective. And their advice should be free from any political bias, as free as the epidemic wave which rolls towards all electors alike, regardless of the political creed of any CANUTE.

The Privacy of Venereal Clinics.

A DIVORCE suit, heard this week before Mr. Justice MCCARDIE, which ended in a decree nisi against the defending husband, has brought to public notice in a particular manner the position of the medical witness. Against the defendant, who made no defence, adultery was proved, the act of cruelty being the communication of syphilis to his wife. To prove this Dr. S. KADINSKY, under whose care at the venereal clinic of the Westminster Hospital the petitioner had been, was called under subpœna. Dr. KADINSKY demurred at being sworn, and handed to the judge a letter from Mr. W. G. SPENCER, chairman of the Venereal Diseases Committee appointed by the House Committee of the hospital, stating that in adopting the national scheme for dealing with venereal diseases the House Committee proposed to abide by the statutory regulations enjoining absolute secrecy on the medical man in regard to patients attending venereal clinics. Mr. Justice MCCARDIE, however, ruled that higher considerations than those which prevailed in regard to the medical profession made it necessary for Dr. KADINSKY to give evidence, when it was elicited that the petitioner was only known at the hospital clinic by a number, but that the witness could identify her personally. No further questions were asked, and the case terminated as stated.

The case is of great importance to medical men, to the public, and to all actively engaged in the attempt ultimately to stamp out venereal diseases. If the absolute secrecy which has been promised in regard to their cases to all who attend venereal clinics can be violated at all, however high the reason, the public resort to these clinics may diminish. And yet all medical hope of the practical control of venereal diseases depends upon the fearless use by the public of treatment centres. Mr. Justice MCCARDIE'S action in a very difficult situation seems to demand an alteration of the law.

Annotations.

"Ne quid nimis."

INVESTIGATIONS WITH A LARGE QUANTITY OF RADIUM.

AN investigation is proceeding at the Middlesex Hospital, London, upon the effects of large quantities of radium in the treatment of cancer. The quantity of radium involved is nearly five grammes of the bromide, and the total quantity of material is used at each clinical application. This investigation arose at the suggestion of Mr. C. R. C. Lyster, until lately the head of the X ray and electrical department of the hospital. He saw the opportunity of putting to a practical test what has often been discussed by radiologists—namely, the treatment of cancer by a much larger quantity of radium than has hitherto been possible to anyone in this country. This suggestion was favourably received by the Medical Research Committee, which has generously provided all the facilities for this investigation, acting in concert with the Ministry of Munitions. Up to the present time it has been a matter for speculation whether the clinical results of exposing a malignant tumour to the rays from, say, a fifth of a gramme of radium for a certain number of hours would be improved if the intensity of the rays were increased 25 times, the time of exposure being correspondingly reduced; the opportunity is now provided for putting such an important question to the test. The fullest use is being made of the radium as occasion allows in the Cancer Research Laboratories of the Middlesex Hospital. There are many matters of fundamental importance in the field of radio-biology which in their turn have awaited the means for their solution. The difficulty hitherto has been to obtain a sufficiently intense source of gamma radiation, and this is now available. The possible danger to those concerned in handling such a quantity of radium as that in question has been carefully considered. When not in use the radium is kept in a safe, inside which is a lead case weighing over a ton, the radium being placed in a cavity in the middle of the lead. The thickness of lead used ensures that not more than 1 part in 1,000,000 of the gamma rays emitted by the radium penetrates the safe. All manipulations are made without contact of the operator's hands and the radium receptacle. It is hoped that in the near future a report upon the clinical and laboratory findings will be submitted to the Medical Research Committee.

These investigations add interest to the announcement made in the *Economic Review* of Dec. 31st, 1919, an invaluable source of weekly information from the foreign press, on the output of radium in France. The following paragraph occurs in the number referred to:—

Output of Radium.

The *Basler Nachr.* (Dec. 7th) reproduces from the General Report of the State of the French Industries the following details on radium production: "Several new radium extraction factories were established during the war. These factories produced on an average 18 g. of the radium yearly. In 1913 this radium was worth 750,000 francs per gramme; to-day it is worth 900,000 francs. The United States are the most dangerous competitors of France. In five years one factory produced 27 g. of radium at a price of 6,700,000 francs. Since 1913 three new radium factories have started in America.

It is interesting to note how the rare elements are coming into commercial production. Canada, for example, has taken up the separation of helium gas on a considerable scale, induced by the want of a gas lighter than air, but which is non-inflammable, for dirigible balloons. The density of helium is just under 2, while that of the atmosphere is 14·4, hydrogen being taken as unity. Not many years ago helium was a chemical curiosity, and its discovery by Ramsay was of great theoretical importance. It is, moreover, a degradation product of radium. Had the war continued a great industry would have been created in Canada, for it was estimated that 2,000,000 cubic feet of this gas could have been produced per month from the natural gas fields of Southern Alberta for use in our balloons at the front. The gases there evolved proved to contain 0·36 per cent. of helium. Not very many years ago we only knew it in traces in a vacuum tube, showing a brilliant yellow light corresponding with a line in the sun's spectrum, and until then it had not been recognised as existent on the earth at all. Radium is a still rarer element, but, as the above record shows, its output is increasing for therapeutical amongst other purposes.

THE SURGERY OF THE PITUITARY: VICTOR HORSLEY'S WORK.

AN excellent treatise, *La patologia chirurgica dell' ipofisi*, by Dr. Giovanni Verga, published in Pavia some ten years ago, draws marked attention to work of Victor Horsley, some of which, the author informs us, has escaped publication. Dr. Verga's book is largely compiled from many sources and deals with the anatomy, physiology, and functions of the pituitary body and the symptoms connected with alterations in its structure or secretion, specially in reference to acromegaly, genito-adipose dystrophy, and cachexia. These three conditions are fully discussed in their relation to the pituitary body. Under the head of pathological anatomy the author brings forward a fund of information gleaned from various observers on congenital malformations, traumatic lesions, inflammatory processes, acute and chronic, in connexion with tuberculosis and syphilis, atrophy, and various degenerations and tumours. Tumours of the organ give rise to secondary changes in the sella turcica and in the organs at the base of the brain, and a photographic reproduction is given from a specimen in the Hunterian Museum by Professor A. Keith, showing the invasion by a pituitary adenoma of the surrounding parts. In the preface the author acknowledges a debt of gratitude to Horsley for permission to publish 12 cases, drawn from his practice in the National Hospital for Paralysis and Epilepsy (Queen-square) and from his private practice. Some of these cases may hitherto have escaped publication, and they are to be found in detail in Dr. Verga's book. They afford valuable information as regards the symptomatology of pituitary tumours, which the author has largely drawn upon in a chapter which occupies a considerable portion of the book. In the cases operated on by Horsley a diagnosis was made from the symptoms and subsequently confirmed. The operation was performed in two stages at an interval of 4–5 days, the first consisting of a free craniectomy in the temporo-parietal region, the second of incision of the dura, raising the temporo-sphenoidal lobe, and extirpation of the tumour. In one case only was the craniectomy frontal and e operation conducted along the anterior cranial ssa. In these 12 cases, there were four deaths, wo immediate and two at dates 8 and 18 months fter operation. Dr. Verga compares these results ith those of v. Eiselberg, Hochenegg, and Hirsh, ho operated by the transphenoidal method of chloffer, in whose cases a large recovery of vision ok place, a fact which, if it took place, is not entioned in Horsley's cases. The book, which is pecially praiseworthy in its large outlook, will be seful to all interested in this branch of surgical athology; it contains an extensive bibliography f over 400 names, showing an extensive range of ollation.

THE INCIDENCE OF CANCER MORTALITY.

Louis I. Dublin[1] has analysed the cancer mor-ality experience of the Metropolitan Life Insur-nce Company of New York during the six years 911–16. He concludes that cancer is more frequent n the industrial class than in those of higher conomic status. This is contrary to the generally eld opinion that luxurious living conduces to ancer, but is in harmony with the close association f cancer with chronic irritation of various kinds. is figures show no evidence of an increase in cancer eath-rates over the six-year period studied. It is orth noting, however, that the cancer mortality in he United States is 30 per cent. less than that in ngland and Wales (70 per 100,000 as compared ith 100–110 per 100,000), and it is hard to believe hat such a wide difference can be entirely real as etween two populations of common origin living nder very similar conditions. The original must e consulted for the details of organ, sex, age, and olour incidence. The paper is interesting as an ndication of the tendency in modern statistical nvestigations of cancer to aim at more and more omogeneous groups by repeated subdivision of he data, so as to eliminate, or allow for, the many ncontrollable factors which influence the incidence f the disease.

THE CORRELATION OF EGGS AND NESTS.

It is not always that *Biometrika* contains papers hich are both interesting and comprehensible to hose untrained in statistical mathematics, but the "coöperative study" in the issue of November last, n the Nest and Eggs of the Common Tern, is an xception. In a previous paper the authors had ade a preliminary study, on material collected in 913, chiefly with a view to determining the extent f the similarity in measurement and in colour etween eggs of the same clutch. This is repeated or observations made in 1914, and the curious esult is reached that both in measurements and n colour and mottling there was conspicuously reater resemblance between the eggs of one clutch n 1914 than in 1913. More interesting, perhaps, o the field naturalist is the attempt to discover hether there is any correlation between the type f egg and the form of nest. The eggs are either reen or brown in ground-colour, and vary con-iderably in extent of mottling, and the nests may e classified into: (*a*) "simple"—i.e., with no aterial collected, and either no hole or merely a epression; and (*b*) "complex," consisting of a ole with nest material accumulated around it. he conclusion arrived at is that although either brown nor green egg layers are the more elaborate nest-builders, the denser brown and lighter green eggs are somewhat more usually associated with simple nests, and lighter brown or darker green with those of more elaborate construction. Larger blotches tend to be found in simple, finer mottling in elaborate nests, and the eggs in mere holes are rounder than those in complex nests. The most interesting problem considered—unfortunately not completely solved—is that of eggs of different colour in the same nest. In about 8 per cent. of the clutches brown and green eggs were found together, and three hypotheses are considered. 1. That the terns consist of two "gentes," one of which lays brown, the other green eggs, and that the mixture arises from the existence of "cuckoo-terns," which lay in other hens' nests. The rarity of four-egg clutches, which must be expected to occur if a cuckoo-tern lays in a nest already containing three eggs, makes this suggestion unlikely. 2. Since the proportion of green eggs increases with the size of the clutch, it seemed possible that a hen lays brown eggs more frequently at first, and green eggs later, but the statistics do not support this hypothesis. 3. The remaining suggestion, regarded as perhaps most probable, is that there are two "gentes," one of which lays chiefly brown and the other chiefly green eggs, but that each may occasionally lay an egg of the other colour. The paper is illustrated with an admirable series of photographs of the terns on their nests.

LATENT MALARIA.

THE clinical symptoms of latent malaria, such as splenomegaly, mononucleosis, basophilia of the red cells, pigmentation of the leucocytes, &c., are often wanting, and it is necessary to use provocative measures to ensure the passage of the parasite into the blood stream or produce a typical febrile attack, with the object of instituting vigorous treatment and eliminating carriers. With this intent many measures have been devised by various observers, and two papers in a recent issue of *Il Policlinico* (Practical Section, Nov. 30th, 1919) are of interest as bearing on this important subject, which has come into prominence owing to the large number of demobilised and discharged soldiers now in this country who have suffered from malaria while on active service. Dr. A. Dazzi experimented on 20 patients with injections of adrenalin, in 12 of whom repeated examination of the blood failed to discover parasites, while in the other 8 only occasional forms in various phases of development were found. His investigations show that the administration of a milligramme of adrenalin was harmless to the patients and did not cause a typical febrile attack, but was always followed by the evidence of the plasmodium in the blood stream. The presence of the parasite was transitory, and began about 20 minutes after the injection, reaching its acme in about one hour. After 24 hours the parasite was no longer demonstrable. In cases in which the parasite was already present in scanty numbers the action of adrenalin caused a striking increase, while it also occasioned a marked diminution in the size of the spleen, except in cases of advanced sclerosis of the organ. This shrinking began a few minutes after the injection and lasted several hours, the action of the drug being apparently to induce contraction of the muscular tissue of all the splenic vessels, causing a kind of squeezing of the whole organ, by means of which the parasites lodged in its substance were expelled into the general circulation. The second paper is by Professor T. Silvestri, who experimented with splenic irradiation with a quartz lamp, the injection of adrenalin, paraganglin, horse serum, &c. In his hands the injection of a milligramme of adrenalin caused a specific febrile attack, rarely on the same day, most often on the following day, and sometimes only after 2–4 days, accompanied by the presence of the parasite in the blood; sometimes a second injection was necessary. He prefers, however, the use of strychnine by mouth in doses of 1–3 mg. daily as being a method which combines certainty with simplicity. As a rule the attack was not delayed beyond the third or fourth day. The mobilisation of the plasmodium, whatever the means used with this object, is to be advocated not only for diagnosis, but also for individual and general prophylaxis and for treatment. Professor Silvestri is of opinion that the practice of mobilising the parasite should form an integral part in the actual treatment of malaria, as only by this means is it possible to arrive at complete sterilisation of the organism and the cure of forms which have hitherto been rebellious to the most energetic treatment.

HIBERNATION OF HOUSE-FLIES.

THE question in a current pantomine song, Where do flies go in the winter-time? gives public expression to the mystery of the winter fly. The problem of finding where, and in what stage, the house-fly passes the colder months of the year, is one that has been of interest to entomologists for many years, but in spite of numerous investigations, hitherto no satisfactory solution has been obtained. At present, opinion is fairly evenly divided between those who consider that the fly passes the winter in the adult stage, and those who believe that the immature stages are of most importance in the continuance of the species to the following year. Very serious objections can be produced against both views. Although occasional adults can be found in human habitations during the winter months, they are exceedingly rare, and hitherto experimental attempts to keep house-flies alive through the winter have failed. On the other hand, although the common house-fly, *Musca domestica*, can certainly pass the winter in the immature stages, either as larvæ or pupæ, the localities in which they breed again present difficulties. Although they have been recorded once or twice from manure heaps, a recent observer, Mr. J. E. M. Mellor,[1] failed to obtain a single example of *M. domestica* after a very careful examination of numerous manure heaps and other likely places during the winters of 1916 and 1916–17. Thirty-nine other species of flies were obtained, some of which occur in houses, but not *M. domestica* itself. In reference to this problem the observations of M. E. Séguy, of Rambouillet, France, are of the greatest interest. These are briefly recorded by Mr. D. Keilin, Sc.D., in an appendix to his article in *Parasitology* (briefly summarised in another column) on flies living in molluscs, and suggest that one way, at least, in which the house-fly may pass the winter is as a larva feeding on snails. M. Séguy placed living snails into a jar containing some larvæ of *M. domestica*, and in eight days the molluscs were completely devoured. Similar results were obtained by confining snails with a few pairs of the adult flies, the newly-hatched larvæ boring their way into the snails and, after devouring one passing easily into another. Apparently in nature the larvæ can live in the snail during the winter for out of 50 snails collected in the middle of January no less than nine contained immature stages of *M. domestica*. Should this important observation be confirmed, a very unexpected light will be thrown upon the mystery of the hibernation of the house-fly, and something may then be done to remedy the fate of the "fly-villas," as they have been called, situated within reach of refuse dumps.

MEDICAL SICKNESS, ANNUITY, AND LIFE ASSURANCE FRIENDLY SOCIETY.

FROM time to time there have appeared in these columns accounts of the monthly meetings of the Medical Sickness, Annuity, and Life Assurance Friendly Society, and we hope that those who have read them and were not members of the Society may have wondered at their neglect to take advantage of an organisation with such practical aims and large possibilities. Since 1884 the Society has been endeavouring to demonstrate to practitioners that they could save some 25 per cent. on insurance premiums for sickness by insuring in this Society, their aim here being partly on the lines of the Medical Insurance Committee, which is now becoming a regular source of income to the best medical charities. Partial success has been obtained in that 3500 members of the medical profession are insured in it, but the profession numbers more than ten times the total. Founded by, for, and run by medical men, a society of this nature should have appealed to a greater proportion of the constituency. Besides the usual life assurances in the form of endowment, annuities, &c., the special feature of the Society, framed to meet the peculiar requirements of medical men, is the sickness insurance. This is in the nature of a permanent contract to the age of 65, renewable and terminable at the option of the insured and not of the company, a most important point; for the insurance of a sum per week, payable in full for the first 26 weeks of incapacity and half the full amount thereafter so long as the incapacity continues, up to the age of 65 provides not only cover for a temporary illness, but also against practically permanent breakdown. Many cases have arisen where men have had to draw this insurance till the limiting age, which proves that such a scheme is required. It seems to us that if more members of the profession availed themselves of the opportunity provided and insured in the Society, we should not have so many sad appeals for assistance from men broken in health. For what, after all, is the fate of the average medical practitioner after, say, a year's illness? Too often his practice has gone, and then comes that steady struggle against odds until the inevitable loss of livelihood. Full particulars of the Society can be obtained from Mr. Bertram Sutton, secretary, Medical Sickness, Annuity, and Life Assurance Friendly Society, at 300, High Holborn, London, W.C. 1.

THE "SCHWEIZERISCHE MEDIZINISCHE WOCHENSCHRIFT."

WITH the first issue of the New Year the *Correspondenz-Blatt für Schweizer Ärzte* increased its format to the familiar size of the *Deutsche* and *Münchener*, and became in external appearance the important medical organ which its contents have ng justified. Established 50 years ago, it has en the medium through which most of the portant discoveries and observations of Swiss ysicians and surgeons, whether French- or erman-speaking, and the proceedings of Swiss edical societies have reached the outside world. ie journal gains by the change in both its main ctions. The length of the line in original com-unications has been reduced from 5 in. in a ngle column to 4 in. in two columns—a boon the reader. In the abstracts and reviews e line has been increased with equal advantage. o one will grudge the editors of the journal, d especially the learned Professor Ernst edinger, the increased recognition which the ange must bring about. Switzerland, by ason of its central position and natural attrac-ons, possesses advantages for post-graduate study which every civilised nation has been quick to 'ail itself, and at the end of last century Kocher, hli, and Langhans at Berne represented the ghest level of surgery, medicine, and pathology. wholesome cosmopolitan spirit pervades medical hools so closely in touch with neighbours of fferent nationality but similar tongue, and this irit is also evident in the Swiss medical weekly. e commend its perusal to those who command e French and German languages, but have sufficient time to study the medical literature of e continent in extenso.

THE RAT HUNT.

THE brief career of the Vermin Repression Society s been a glorious one, for, unlike its two pre-cessors, it has secured the passage through rliament of a Rats and Mice Act, which if pro-rly administered will go far to rid the country of a ngerous and destructive pest. Lord Aberconway, airman of the Society, who presided at the nner, held at the Connaught Rooms, London, Friday, Jan. 9th, to celebrate the passing of the t, queried whether, the work of the Society ving culminated in legislation, it might now be sbanded. But the Government representative the dinner, Sir Arthur Griffith-Boscawen, id that he regarded the Society as only the beginning of its work. The new Act npowered any local sanitary authority to carry it the destruction of rats on the premises of a egligent private owner, charging him with the cpense incurred. The Act also empowered the inistry of Agriculture to do the same in regard to egligent local authorities. The Vermin Repression ociety should, he thought, undertake the task of eeping the new Ministry up to the mark. It is ot necessary any longer to dwell upon the onomic loss occasioned by rats. In the nited States they annually consume 35 to) million dollars' worth of grain; in Great ritain the whole cost of old-age pensions ight be saved. Fortunately, useful knowledge is cumulating for an effective campaign. To the nployment of viruses attaches the double objec-on of the probable adaptation of the vermin to the oison and the possible development of virulence r man. They are being discontinued in favour of iemical agents, which have a selective toxicity r the rat alone, and do not, like strychnine, rsenic, and phosphorus, leave a trail of unintended ictims. At present barium carbonate and extract f squills hold the field. Two grains of the former iffice to kill a medium-sized rat, although innocuous to domestic animals, cats and chickens, and the specific toxicity of squills appears to be still greater. We badly need for common use an up-to-date comparative table of poisons, with their toxic and lethal doses per kilo of body-weight for different members of the animal kingdom. Apart from efficient tools, organisation is, of course, the chief requisite in a successful anti-rat campaign. In one of the home areas the county organising officer has recently conferred with representatives of most of the local sanitary authorities in the county, and a pamphlet has been issued detailing an effective campaign and the precise measures of carrying it out. We may hope that the campaign will attain the same notoriety as that organised in Denmark by Emil Zuschlag in 1907, when this indefatigable enemy of the rat was freely caricatured as a Robespierre.[1] If this happens, the brown rat may soon be hunted down as successfully by man as the brown rat has already eliminated its predecessor, the black rat. Whatever else is done, at least all storeplaces of food should be rat-proofed.

THE King of Italy has conferred the Cross of the Order of the Crown of Italy on Sir Donald MacAlister, K.C.B., President of the General Medical Council, for services in the war, and the special permission to wear the decoration in this country has been granted him by Royal Warrant.

Sir John Bland-Sutton has been elected first President of the Association of Surgeons of Great Britain and Ireland, which held its inaugural meeting on Jan. 8th, Sir Rickman Godlee presiding. The Association is the outcome of a feeling expressed by Sir Berkeley Moynihan, six years ago, that no adequate occasion at present exists for a fully representative debate on surgical topics.

THE number of medical students registered during the past year is 3393. The figures for the previous years, as supplied by the Registrar of the General Medical Council, are as follows:—

1912	*1913*	*1914*	*1915*	*1916*	*1917*	*1918*
1397	1480	1600	1918	1875	2150	2253

The number of dental students registered during the past year is 612, and the figures for the previous years are as follows:—

1912	*1913*	*1914*	*1915*	*1916*	*1917*	*1918*
336	361	294	217	158	143	161

A SPECIAL general meeting of the Royal Society will be held on Jan. 22nd, at 3.30 o'clock, the Prince of Wales having expressed his intention to attend for admission into the Society on that day.

THE announcement to the effect that Professor Starling has been appointed Director of Medicine at St. Thomas's Hospital (University of London), in connexion with the formation of University units, is incorrect.

INDEX TO "THE LANCET," VOL. II., 1919.

THE Index and Title-page to Vol. II., 1919, which was completed with the issue of Dec. 27th, is given in this number of THE LANCET, and will not be issued separately.

MEDICAL PRACTICE IN BOLSHEVIST HUNGARY.

(FROM OUR OWN CORRESPONDENT.)

ALONE among the "intellectual" occupations, medical practice was regarded as "productive" occupation by the Bolshevists, and the physician was allowed to carry on either as a private practitioner or as public employee. While lawyers, professors, and judges in towns were not allowed to keep more than three rooms, including office, the remainder being filled with labourers, medical men were left with living rooms, separate office, and reception rooms.

In the earliest days of Bolshevism the rumour spread that the medical profession would be nationalised, and had the regime lasted longer it would doubtless have happened. The proposal was for every physician to receive from the State a salary of 30,000 crowns (£2500 peace value, at present not worth more than £150) without distinction of rank or position. He was to be at the service of the public with his best knowledge for six hours a day. Up to 32 years of age only practice in public hospitals or in villages was to be allowed. After six years' practice in the country the physician might settle in a town. The one exception in regard to higher salary affected university professors, who were to receive 50,000 crowns a year. The treatment of the public was to be wholly gratuitous; no private practice would have been allowed, and the acceptance of fees or gifts for medical work would have been subject to prosecution.

Almost all the intellectual classes, the so-called "lateiner" occupations, were handled with animosity as "bourgeois" people. As regards bread, they were rationed in the third class, with 250 g. a day. The medical profession, luckily, ranked in the second class, along with iron and metal workers, as "brain labourers," with 350 g. In the first class were soldiers of the Red Army, with 500 g. Medical men were compelled to combine in trade-unions, since only members of such unions were allowed to purchase (at maximum prices) foodstuffs, industrial articles, clothes, or boots. Public baths, libraries, and theatres were only open to trade-unionists. Many who remained outside had to dispense with the most elementary necessities of life. Their children were unable to obtain school-books or clothes, and in the last months of Bolshevik rule were a sorry sight.

In the medical faculty of the University itself professors of world-wide repute were thrown out of position on account of their membership of certain religious societies or for having previously shown anti-socialistic feeling. On the other hand, former members of socialist clubs, without special qualification, have been promoted to the rank of lecturer and even professor. Students applying for admission to socialistic trade-unions have been aided by the State with a monthly support of 500 crowns. The teaching of religion has been prohibited, even in elementary and secondary schools, and the theological faculty of the University has been closed. To the medical faculty an edict went out that the doctrines of Marx and Lassale should be the subject of lectures occupying six hours weekly.

Even after the termination of Bolshevism the medical faculty was not suffered to rest in peace. The authorities of Budapest removed from their positions at the municipal hospitals all doctors who obtained advancement during the Bolshevik era. Dr. Emile Grôsz, professor of ophthalmology, who was president of the Hungarian section at the International Medical Congress held in London during 1913, was an object of rancour by the reactionary elements of his audience, and has been driven out of his institute because he undertook the position of "confidential man" of the medical faculty during Bolshevism. A similar fate has met Dr. Plosz (lecturer on pathological chemistry) and Dr. Illyés (operative urology). The present position of the medical profession is not rosy. Although medical fees have been raised twenty-fold, most medical men are suffering great hardships. Whereas in peace time a physician in Budapest was satisfied with 10 crowns (8*s.*) for a ca to the patient's house, he has now to ask 100 crown (£4 in peace value), and even so he is unable to ear enough to cover the current prices of such things a milk at 10 crowns a litre, bread at 20 crowns a kg. matches at 2 crowns a box, eggs at 5–6 crowns apiece and boots at 800 crowns a pair. High fees involve fewe patients; the general lack of work and shortness o money among the labouring classes has curtailed thei ability to pay medical fees. These facts, in conjunction with the great want of foodstuffs and fuel in the city are causing the mass emigration of medical men from Budapest. Daily 20–30 physicians are leaving the capital with their families to seek easier maintenance and better earnings in the villages and smaller towns.

Nagyvárad.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Irish Medical Committee and the Irish Public Health Council.

A MEETING of the Irish Medical Committee was held in the Royal College of Surgeons on Jan. 6th, Mr. R. J Johnstone in the chair. A letter was read from Dr E. Coey Bigger, chairman of the Irish Public Health Council, stating that at a recent meeting the Council had had under consideration the question of the reform of the medical service in Ireland, and had decided to recommend to the Irish Government the establishment of an Irish Medical Service appointed by competitive examination, with fixed scales of salaries, rights to pension, study leave, &c. Consequent on this decision, the Council had also considered the functions and duties to be entrusted to the medical officers of the service, but before coming to a decision the Council wished to have the assistance of representatives of the medical profession. In particular, advice was sought as to the classes of the community which would be entitled to medical attendance in connexion with the service. He therefore requested the Irish Medical Committee to nominate a few representatives to attend the next meeting of the Council.

The Irish Medical Committee selected the following representatives: Mr. R. J. Johnstone, chairman; Dr. Joseph Power, vice-chairman; and Dr. J. S. Darling (Lurgan), Dr. J. M. Day (Dublin), President of the Irish Medical Association, Dr. W. R. Morris (Waterford), Dr. O'Connor (Queenstown), Dr. W. J. O'Sullivan (Killarney). Dr. E. Thompson (Omagh), Dr. H. T. A. Warnock (Donegal), and Dr. W. W. Murphy (Coolgreany). The deputation was instructed to suggest that the class to be attended by the medical service should be restricted by an income-limit of £3 a week, and that a minimal salary of £650 a year for medical officers should be suggested. The deputation was also appointed as a standing committee to watch the proceedings of the Irish Public Health Council, and give it any further assistance it might require. The interview of the deputation with the Irish Public Health Council took place on the following day. Dealing with other matters, the Irish Medical Committee passed the following resolutions:—

> (1) "That the scheme in existence for medical attendance on discharged disabled soldiers and sailors has proved unsatisfactory both as to the inadequacy of the remuneration and to its method of distribution."
>
> (2) "That the remuneration for certification under the Insurance Act is insufficient, and should be increased by the sum which is returned unexpended each year to the Treasury out of the Equivalent Grant. That as Ireland has to pay one year with another her full quota towards the administrative expenditure of the Act in England, Scotland, and Wales, we consider it grossly unfair that the Irish medical profession should be deprived of their money."

A letter was read from Dr. O'Sullivan stating that the medical practitioners in the Limerick area had refused the capitation fee for medical treatment of Post Office employees, and were now working a scheme under which they received 10*s.* a visit, exclusive of medicines. This arrangement was considered by the Irish Medical Committee to be quite satisfactory.

The Humane Slaughtering of Animals.

suggestive discussion took place in Belfast, at a
eting held on Jan. 9th under the ægis of the Ulster
iety for the Prevention of Cruelty to Animals, whose
mbers protest against the methods of slaughtering
mals at present in vogue at the Belfast city abattoir,
l urge the substitution of the pistol (as a more humane
thod) for the pole-axe. Those on one side urged
t the system in use was needlessly cruel and
uman, and that it arose from ignorance and
judice. On the other hand, those members of
corporation in charge of the Markets Committee
the City Corporation, who had visited other places,
ged that the humane killer they found was
much in use. The butchers, who said they were
pared to adopt the most humane method which
ld be devised, objected to the pistol (so-called
nane plan); meat-traders declared that the meat of
animal thus killed did not keep because the animal
not bleed sufficiently, and that, owing to the tissues
ng full of blood, decomposition set in immediately,
ecially in summer weather. Further, it was alleged
t the blood of the animal killed by the humane
thod was much darker in colour than that of the
mal killed by the pole-axe, and consequently
flesh was darker; and the speakers on the
chers' side asked for an explanation of this alleged
t. The upshot of a discussion—in which there was a
rked difference of opinion—was satisfactory, for the
ster-butchers, who naturally resented any charge of
umanity, gave an assurance that if it could be
ved that the pistol was the better method of killing
mals, and that it could be used with economic
antage, they were prepared to adopt it. It lies now
h the Ulster Society for the Prevention of Cruelty to
imals to accept this challenge and to prove their case
the satisfaction of the meat-traders, and the con-
ners of such animal food.

Accidental Shooting of a Medical Man.

n unfortunate incident happened in co. Clare on the
ht of Jan. 3rd. A police patrol had been attacked
l shots were fired on both sides. The attackers had
l, when Dr. Denis J. Keane, a highly respected
dical man of Ennistymon, returning from a visit to
atient, came along the road in his motor-car. The
ice, thinking he had some connexion with the party
t had attacked them, fired at Dr. Keane, wounding
ı in the forearm. He is progressing satisfactorily.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

New Health Bill.

HE Victorian Government has introduced a new
asure dealing with public health administration.
e main features of interest are that the existing
ırd of Public Health, which is a body of lay
nicipal representatives, is to be abolished and
laced by a commission of seven members nominated
the Governor in Council. In the Bill as it stands
of these are to be medical men, but it is possible
t this will be altered, as the medical profession in
toria is not in favour in Parliamentary circles owing
he continued deadlock between the B.M.A. and the
ndly societies. The most hopeful provision of the
l is the power given to create health areas under
ole-time officers, but it all remains to be done by
clamation. The Labour Party and a section of the
ss clamour for some measure of free medical attend-
e by Government doctors, but it is improbable that
ch in that direction will be enacted under the
sent Bill. At the same time "the health of the
ple" has become a political catchword in Federal
itics, and the Federal quarantine authorities are
ing at taking the whole control of public health
ninistration. It appears almost certain that some
posal for a national medical service of a clinical
ure will be part of such a control, whichever side
pens to come into power. In New South Wales a very considerable degree of State medical attendance already exists, and the Adelaide General Hospital in South Australia has been a Government institution for many years.

The Custody of a Child.

The application of Dr. J. S. Macpherson, C.M.G., to be given the custody of his daughter by a former wife, which has already been mentioned in this column,[1] has been the subject of further litigation. On the order of the High Court the father was entitled to succeed, and his daughter was handed into his care. They left together by the Sydney express en route for Canada. At Albury, where it is necessary to change trains, the girl disappeared and, it is alleged, was driven away in a motor-car belonging to a relative of the Thornley family, who are disputing the father's claim. Dr. Macpherson then brought proceedings to compel the production of the girl. The witnesses who were called all professed entire ignorance of the girl's whereabouts, although it was admitted she was quite safe and happy. Mr. Justice Hood decided there was no evidence to commit anyone for conspiracy, and the counsel for the prosecution then asked for an adjournment sine die. There the matter now stands. It is understood the daughter has expressed her determination to remain with her mother's relatives.

University of Sydney.

At a recent election of ten members of the Senate of the Sydney University four members of the medical profession were elected, including a lady, Dr. Constance Darcy, who is regarded as representing specially the interest of the women graduates.

Federal Medical Relief Fund.

The Federal Medical Relief Fund for medical officers suffering as a result of the war, which was advocated by the various State branches of the B.M.A. and fixed at a prospective sum of £50,000, has reached a total of £9015. This sum does not represent more than a small number of subscribers in each State, and the response has not come up to the expectation of the promoters. The lukewarmness appears due not to any disapproval of the scheme, but to a doubt that there is any occasion to raise such a large amount for the purpose. Under the Government repatriation legislation there appears to be local difference of attitude towards the application of returned medical men for assistance in resuming practice. In Victoria such applications have been refused, but in other States it is said that assistance has been given.

Post-Graduate Course.

A very successful post-graduate course for returned medical officers and others has been carried out by the Victorian branch of the B.M.A. The whole of the Melbourne general and special hospitals were open to visitors, and a special programme was arranged in such directions as were likely to prove of most interest. The courses at the Women's Hospital and at the Children's Hospital were largely attended, while the clinics of other special institutions and the classes at the teaching hospitals were much appreciated. It is probable that this course, which extended over a fortnight, will be made an annual function.

Strange Fatality.

The death of Dr. Norman Gerrard was announced recently under peculiar circumstances. Dr. Gerrard graduated from the Melbourne University in 1905, and at the time of his death was in country practice in Victoria. He developed a sore-throat, which was accompanied within a few hours by such a sense of suffocation that he attempted to perform tracheotomy on himself. At the inquest it was stated that the incision had been correctly made, and that death had resulted from hæmorrhage into the trachea.

Fatal Barium Meal.

A patient in the Sydney Hospital died after taking a barium meal. At the inquest a verdict stated death resulted from the effects of a soluble barium salt, and the coroner said if the hospital regulations had been carried out there would have been no catastrophe. It appeared that the barium compound had not been directly issued from the dispensary for the case, but had been obtained from another ward because the dispensary was closed, and was a sample issued some time previously for a case for which it had not been used.

[1] THE LANCET, Nov. 8th, 1919, p. 849.

Nov. 18th, 1919.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Recrudescence of Influenza.

INFLUENZA appears to be recurring in Paris. Every day there is a slight increase in the number of cases, which are not, however, very serious, nor is the mortality nearly as formidable as that of last year's epidemic. The most striking feature of the present outbreak is the appearance of the disease in a new form. The pulmonary symptoms are less severe; the temperature runs fairly high, but is irregular, with inexplicable remissions. Vomiting and constipation may be present and, above all, a peculiar torpor, a sort of stupefied condition, with a tendency to sleep, shows the marked effect of the infection on the central nervous system. Deaths have been recorded, but in general the patients recover after two or three weeks. The Administration de l'Assistance Publique has decided to group all such cases together under the care of Dr. Renon at the Hôpital Necker, so that a detailed study can be made of them. Blood cultures have been tried, but no very clear results have been obtained up to the present.

Encephalitis Lethargica.

Another epidemic is at the moment attacking Paris and the Paris district. Professor Netter noted its appearance in the spring of last year and called it encephalitis lethargica. Its characteristic features are bad headache, with paralysis of the oculo-motor nerve, and a continuous inclination to sleep; fever runs high. No special germ has been isolated in culture. Post mortem there is a marked congestion of all parts of the brain. The nature of this malady is not yet well understood. At any rate, it is not sleeping sickness, brought into France by the black African troops. During the course of last year a few cases occurred, but the disease seemed to be stamped out at the end of the summer. M. Netter has just notified eight new cases to the Academy of Medicine. Two are dead, two have recovered, and four cases are still under treatment.

Microbic Defence against Infection.

Dr. Roux, Director of the Pasteur Institute of Paris, has brought to the notice of the Académie des Sciences two sets of observations made by one of his pupils, M. d'Herelle, which seem to open a new chapter in the general pathology of infection. He has shown that in the stools of convalescent dysenteric patients a filterable virus, invisible to the ultra-microscope, can be found. It can be cultivated and has a remarkable bacteriolytic action on Shiga's bacillus. When introduced into dysenteric patients it has a selective action on this bacillus, and ends by destroying it. This action differs markedly from the well-known effect of the lactic acid bacillus, which merely hinders the development of intestinal bacilli by modifying the medium in which they grow. In this case the invisible virus has a direct action on Shiga's bacillus, which is actually dissolved thereby. Patients suffering from dysentery have been treated with much success by cultures of this filter-passer, which appears innocuous to man and which will possibly in the future replace anti-dysenteric serum. The virus shows similar bacteriolytic action towards other bacteria. M. d'Herelle has been able by this method to treat cholera in fowls—a disease nearly always fatal. M. Kabeshima has similarly been able to render rabbits immune to the dysentery bacillus. This bacillus, introduced into the intestine of rabbits who have previously been fed with a culture of M. d'Herelle's invisible filter-passer, rapidly disappeared without producing any sympto of dysentery. M. Roux has pointed out that we ha here a discovery of considerable importance in t future treatment of infective diseases. We can fores henceforward the adoption of a new treatment dysentery, and perhaps of enteric, founded on th method.

Rectal Injections of Bile for Constipation.

MM. Bensaude and Vicente, in order to make use the well-known stimulating action of bile on t intestine, which they have verified by X ray observ tions, have used ox-bile injections for constipation wi complete success. They use a dose of 4 g. to 5 g. of d extract of ox-bile dissolved in a quarter of a litre tepid water. After five to ten minutes a comple evacuation of the bowels takes place, generally witho colic or pain of any sort. These injections act as well acute as in chronic constipation; they have succeed in cases where the classical injections of senna or sodium sulphate have failed. In several cases b injections have been repeatedly used for six mont without either intolerance or diminution of action bei exhibited. Historical investigations have shown th these facts were known from the most ancient time and that the Egyptians themselves were aware of th method of treatment.

Jan. 10th.

THE FELLOWSHIP OF MEDICINE.

AT a meeting of the general executive committee the Fellowship of Medicine and Post-Graduate Medic Association, held on Jan. 5th at No. 1, Wimpole-stre London, W., Sir HUMPHRY ROLLESTON presiding, resolution was passed in silence recording the profou sorrow of the Association at the loss of their Preside Sir William Osler, and expressing the belief that witho his guidance and support the success they have obtain would have been impossible.

The report of the special subcommittee appointed draw up a plan of future work was submitted a approved as follows:—

1. *Post-Graduate General Courses for General Practitioners* A series of courses dealing with the various clinical subje in the medical curriculum, from the general practitione point of view, each lasting a fortnight or more, should arranged by single institutions or by groups of institutio These institutions would be of two kinds: (*a*) those, such the existing post-graduate institutions, providing po graduate instruction through the greater part of the yea and (*b*) those undergraduate schools which are willing provide short courses from time to time.

2. *Post-Graduate Advanced and Special Courses.*—Co secutive series of advanced courses, each series deali with one clinical subject from the specialist or advanc point of view should be arranged by the educational su committee with committees elected annually by separa meetings of London teachers interested in each subje which should include the councils of the correspondi sections of the Royal Society of Medicine.

3. *Post-Graduate Students Preparing for Special Exami tions.*—Courses for special examinations should be arrang for by individual schools as has been done in the past.

Pending the circulation of definite proposals for t future post-graduate programme a request has be circulated to medical schools and hospitals that a steps which are being taken to draw up a program for post-graduate courses should be held in abeyance.

THE INCREASE OF MEDICAL FEES.—**At a large attended meeting of the practitioners resident in the area the Kensington Division of the British Medical Associati the following resolution was passed unanimously:—**

> "That this meeting of medical practitioners resident in Hamm smith, Kensington, and Paddington agrees that, owing to altered value of money, it is necessary that the fees for p fessional work be increased by *at least* 50 per cent. on the f prevailing before the war, and calls upon all practitioners resid in these areas to loyally carry out this recommendation, as is be done in all parts of London and the provinces, it being underst that in cases (known to the practitioner) where such an incre would be the infliction of a hardship he will use his own estim of the fees to be demanded in these circumstances."

"Audi alteram partem."

'ENEREAL DISEASE AND PROFESSIONAL SECRECY.

To the Editor of THE LANCET.

SIR,—Mr. Justice McCardie's ruling in a recent vorce case, by which he set aside the principle of ofessional secrecy and compelled a medical man to ve evidence as to syphilitic infection, will have an verse influence on the prevention and treatment of nereal disease. The explanation given, that in a urt of law there were "even higher considerations an those which prevailed with regard to the position medical men," is beside the point. The question not one of the position of medical men, but one of blic health. If persons infected with venereal disease e liable to have the fact published in the public press ey will avoid places of treatment where their names e registered, and will tend to resort to quacks. Again, e reason given for the abolition of secrecy in the case der discussion—to obtain evidence of cruelty—is ite inadequate. Every medical man who has had ch cases to deal with knows the difficulty, often the possibility, of tracing the source of infection, and any idence obtained is open to so many sources of error to be absolutely unreliable.

I am, Sir, yours faithfully,
C. F. MARSHALL, M.D., F.R.C.S.
Velbeck-street, London, W., Jan. 14th, 1920.

*** We have dealt in another column with the portant case referred to by our correspondent.—ED. L.

MEDICAL MEN IN PARLIAMENT.

To the Editor of THE LANCET.

SIR,—It will, I think, be of interest to your readers to ect their attention to the fact that the recent return of eutenant-Colonel F. E. Fremantle, F.R.C.S., F.R.C.P., Member for St. Albans, gives the medical profession representatives in the House of Commons, exclusive the two holding cabinet rank, and that of these no s than seven have accepted seats on the Council of is Federation. The recent elevation to the peerage Sir Bertrand Dawson, G.C.V.O., C.B., gives the ofession its only direct representative in the House Lords, and the new peer also has a seat on our uncil.

Colonel Fremantle, in writing to thank our Executive mmittee for the help it was able to afford him in the cent by-election, states: "My need was obviously rally all the forces I could muster to my aid, and no e answered the call more promptly or helpfully than l the Executive Committee of the Federation. I am re that the help it gave was of great value, and I like think that its congratulations are on the prospect of y being of some service both to the country and the ofession."

I am asked to thank all those who assisted the ndidate, at the request of the Federation, which is couraged by the result of the election, to make further deavours to increase medical representation.

I am, Sir, yours faithfully,
N. HOWARD MUMMERY,
General Secretary, British Federation of Medical and Allied Societies.
, Vere-street, W. 1, Jan. 9th, 1920.

SUBCUTANEOUS EMPHYSEMA IN PARTURITION.

To the Editor of THE LANCET.

SIR,—Mr. J. Good's letter in THE LANCET of Jan. 10th scribes a case of subcutaneous emphysema in parturin. I had a similar case myself while in charge of a our ward in a Poor-law infirmary some months ago.

The patient [redacted] a primipara, aged 19. She was extremely thoric and heavily built, but appeared, however, to be in perfect health. During the first and second stages of labour she made very violent efforts at delivery, and as these were unavailing I terminated labour with forceps under light chloroform anæsthesia. On the following day I found that there was a large area of subcutaneous emphysema covering the upper part of the chest. The distribution was bilateral. It extended upwards as far [redacted] the angle of the jaw on both sides, and downwards as far [redacted] the fourth intercostal space. It was especially noticeable in the region of the apices of the lungs. Crepitus was elicited over the whole of this area. During the next few days the patient coughed up a moderate quantity of frothy sputum, and the emphysema gradually disappeared. The temperature rose to 100° F. on the second day, and remained at about that level for three days. This condition was accompanied by a slight cystitis. The urine was alkaline, somewhat offensive, and contained a trace of albumin. At no time did the patient complain of any pain or distress.

At the end of three weeks both conditions had completely subsided, and the patient was discharged from hospital.

I am, Sir, yours faithfully,
J. W. CRAW.
Northwich, Jan. 12th, 1920.

A SAYING OF DR. GEE'S.

To the Editor of THE LANCET.

SIR,—In his interesting lecture, "The Dying-out of Native Races," reported in the last two issues of THE LANCET, Dr. W. H. R. Rivers quotes Dr. Gee as saying "Medicine has three parts: the first is diagnosis; the second is diagnosis; and the third is diagnosis." Dr. Rivers adds in a footnote that he has been unable to discover to whom this aphorism is originally due. Is it not probable that Dr. Gee was paraphrasing the dictum attributed to Demosthenes, who is said to have declared of his art, that it had three parts: the first was action; the second was action; and the third was action?

I am, Sir, yours faithfully,
THOMAS HORDER.
Harley-street, W., Jan. 11th, 1920.

"THE JUSTIFIABILITY OF THERAPEUTIC LYING."

To the Editor of THE LANCET.

SIR,—Dr. Hildred Carlill, in replying to Dr. C. S. Myers's letter in your issue of Dec. 27th, observes, in defence of the methods he adopted in the case he reported (THE LANCET, Dec. 20th, 1919), "that the principles of this treatment of 18 months ago differ in no way from those to which I would have consented in the case of similar illness in a member of my own family." This is certainly some support for Dr. Carlill's reasoning, but no justification for his therapeutic procedures. In trephining a patient for a disorder of psychical origin Dr. Carlill has converted a functional disorder into an organic disability, and, moreover, one which renders the patient handicapped for life.

Such treatment seems to me to be worse than the disorder against which it is directed, and in my opinion constitutes an unjustifiable procedure and a dangerous precedent. Dr. Carlill complains that Dr. Myers offers no alternative treatment. Almost any treatment would be preferable, even none at all. If the medical profession has to resort to trephining for mental disorder its therapeutic armoury must indeed be empty.

Dr. Myers doubts whether deliberate lying is ever justified in therapy, to which Dr. Carlill replies that "deception in one of its many guises will probably continue to be used by some doctors for some cases as long as treatment of disease lasts ......" While admitting the truth of this statement, it may be opportune to emphasise that treatment by "suggestion" is not synonymous with deceit, and psycho-therapy includes various procedures other than "suggestion." The methods Dr. Carlill utilised in treating his patient appear to have been confined to hypnotic suggestion and crude suggestion conveyed by deception. Such a course as the analysis of the patient's mind, in an endeavour to discover the mental elements underlying these attacks, does not appear to have been considered. The attempt to discover a psychological basis for a mental state seems to be more reasonable than the bludgeoning of a symptom by such a procedure as Dr. Carlill describes.

It would be interesting to see in what new guise the "relieved" symptom reappears.

I am, Sir, yours faithfully,

Queen Anne-street, W., Jan. 10th, 1920. IVO GEIKIE COBB.

"MIND AND ITS DISORDERS."

To the Editor of THE LANCET.

SIR,—It is not the function of an author to answer critical reviews of his work, and it is not my intention to reply to your reviewer of my third edition of "Mind and its Disorders."[1] Owing to the intrinsic nature of psycho-analysis any such work is bound to meet opposition and denunciation, and this always will be so; but on account of Dr. J. E. Nicole's letter, in your issue of Jan. 10th, I feel called upon to clear the ground for any discussion which may arise therefrom and to explain why, after adopting a Freudian psycho-pathology of the maniacal-depressive psychosis, I have retained the account of my old "intraneuronic intoxication" hypothesis of that disorder.

The reasons are mainly three. In the first place, the two views are not incompatible, for psycho-pathological experience reveals that mental mechanisms may and do sometimes produce quite remarkable organic changes in the tissues. Secondly, the psycho-analytic point of view is extremely difficult to convey; for example, that there is a logic of feeling as well as of reason. The number of people who are unable to view matters from a Freudian standpoint is therefore very large; and it was partly out of consideration for these that it was decided to include the other hypothesis, so that they would not be left "high and dry" without a working scheme. Lastly, supposing the "intraneuronic intoxication" hypothesis to be all wrong, my experience has been that it helps students to remember the signs and symptoms of mania, melancholia, and energic stupor for examination purposes.

My own view of the mechanism of the above psychosis is that the primary factors are purely mental, that these induce metabolic changes in the tissues, and that these changes react further upon the mind in the manner detailed in the book.

I am, Sir, yours faithfully,

Cavendish-square, W., Jan. 13th, 1920. W. H. B. STODDART.

THE PROBLEM OF VENEREAL DISEASE.

THE following statement has been sent to THE LANCET by the General Secretary of the National Council for Combating Venereal Diseases:—

A good deal of confusion has arisen in the public mind with regard to the distinction between the National Council for Combating Venereal Diseases and the recently formed Society for the Prevention of Venereal Disease. Both bodies take their stand on common ground in desiring the reduction and final elimination of the terrible scourge of syphilis and gonorrhœa from our national life. But they approach and deal with the problem from entirely different points of view. Basing their opinion on the findings of the Royal Commission on Venereal Disease and the experience gained during the war, the National Council contends that the strongest weapons available are, first, the education of all classes and sections of the community as to the causes, nature, and results of these diseases, and, secondly, the earliest possible treatment of infected persons. They also recognise that immediate local cleanliness after exposure to the risk of infection will reduce that risk, but, unfortunately, it is by no means an infallible preventive. Where propaganda stating that it is so has taken place, the amount of venereal disease has materially increased—vide the incidence among the Australian troops, starting as it did at 130 per 1000 and rising to 147 per 1000 as compared with the British troops' incidence of 38 per 1000. The Society for the Prevention of Venereal Disease consider that immediate self-disinfection is the only measure worthy of consideration from either a medical or social point of view. In this they are in disagreement witl the opinion expressed by Lord Sandhurst on behalf o the Government during the debate in the House o Lords on Dec. 10th, when he stated that "even i circumstances specially favourable to instruction in th method proposed the risk of venereal disease is by n means certainly avoided. ...... How much more, then would this be the case, and how far removed should w still be from secured immunity, with the civil population, in respect of whom the arrangements as to instruction and discipline adopted for the military woul obviously be quite impossible?" The same view i held by an almost unanimous majority of medica officers of health and clinic officers throughout th country. Many of those who support the policy of th Society for the Prevention of Venereal Disease bea illustrious names rightly honoured in the medical worl —but they do not represent those medical men an women who have had long and intimate experience o the practical problems involved in the successfu prevention and treatment of venereal disease. Th Society for the Prevention of Venereal Disease is therefore completely at variance with the National Counc in regarding immediate self-disinfection as the one an only practical measure by which venereal disease ca be exterminated. The National Council considers i but one of several weapons to be added to the armour of education and prompt treatment.

81, Avenue Chambers, Southampton-row, London, W.C. 1.

URBAN VITAL STATISTICS.

(Week ended Jan. 10th, 1920.)

English and Welsh Towns.—In the 96 English and Wels towns, with an aggregate civil population estimated a 16,500,000 persons, the annual rate of mortality, which ha been 14·6, 12·0, and 16·2 in the three preceding weeks, fell t 15·8 per 1000. In London, with a population slightly excee ing 4,000,000 persons, the annual death-rate was 15·7, or 1 per 1000 below that recorded in the previous week, whil among the remaining towns the rates ranged from 5·8 i Eastbourne, 6·2 in Wolverhampton, and 7·0 in Merthy Tydfil, to 24·6 in Sunderland, 25·7 in Bootle, and 26·5 i Grimsby. The principal epidemic diseases caused 337 death which corresponded to an annual rate of 1·1 per 1000, and comprised 107 from measles, 87 from diphtheria, 60 from infanti diarrhœa, 51 from whooping-cough, 26 from scarlet feve 5 from enteric fever, and 1 from small-pox. Measles cause a death-rate of 1·5 in Plymouth and in Preston, 1·6 in Leed 1·7 in Darlington, 2·0 in Dewsbury, and 3·8 in Bootle; an diphtheria of 1·3 in Walthamstow and in Wigan. Th fatal case of small-pox was registered in Gateshead. Th 73 deaths from influenza were 21 in excess of the numb in the previous week, and included 16 in London, 10 i Birmingham, 5 in Leeds, and 4 in Newcastle-upon-Tyn There were 2809 cases of scarlet fever, 1899 of diphtheri and 2 of small-pox under treatment in the Metropolita Asylums Hospitals and the London Fever Hospital, again 2926, 1873, and 0 respectively at the end of the previou week. The causes of 51 deaths in the 96 towns we uncertified, of which 7 were registered in Birmingham, 6 i London, and 4 in St. Helens.

Scotch Towns.—In the 16 largest Scotch towns, with an aggr gate population estimated at nearly 2,500,000 persons, th annual rate of mortality, which had been 13·2, 14·8, and 15 in the three preceding weeks, further rose to 16·6 per 100 The 402 deaths in Glasgow corresponded to an annual rate 18·8 per 1000, and included 9 from measles, 4 from dip theria, and 3 from infantile diarrhœa. The 97 deaths i Edinburgh were equal to a rate of 14·8 per 1000, and include 2 each from measles and diphtheria and 1 from infanti diarrhœa.

Irish Towns.—The 138 deaths in Dublin corresponded an annual rate of 17·3, or 2·7 per 1000 below that recorded i the previous week, and included a fatal case each of scarl fever and infantile diarrhœa. The 150 deaths in Belfa were equal to a rate of 18·9 per 1000, and included 19 fro measles, 3 from scarlet fever, and 1 from infantile diarrhœ

BRISTOL DISPENSARY.—At the annual meeting this charity Mr. Fenwick Richards retired after many year energetic service as chairman and treasurer amid gener regret. This charity, which supplies domiciliary as well out-patient treatment, is in low water financially and i premises are in need of repair. The new chairman is M Norman Wills, a younger representative of the family th has done so much for Bristol, his brothers, Mr. H. H. Wil and Mr. G. A. Wills, being presidents of the Royal Infirma and the General Hospital respectively.

[1] THE LANCET, Dec. 20th, 1919, p. 1143.

Medical News.

UNIVERSITY OF CAMBRIDGE: DIPLOMA IN RADIOLOGY AND ELECTROLOGY.—Under the auspices of the Fellowship of Medicine and Post-Graduate Medical Association the British Association of Radiology and Physiotherapy have arranged a series of lectures in radiology and electrology, qualifying for the Cambridge Diploma, to be given at the house of the Royal Society of Medicine, 1, Wimpole-street, London, every Monday and Wednesday at 5.30 P.M., commencing Feb. 2nd, 1920. The opening lecture will be given by Dr. W. J. Turrell of Oxford, who will deal with the history of electrotherapeutics. For those wishing to take the diploma the fee for the course is £15 15*s.*, with the additional enrolment fee of 10*s.* 6*d.*, to the Fellowship of Medicine and Post-Graduate Medical Association, but members of the Fellowship Post-Graduate Course are invited to attend any of the lectures advertised. A detailed syllabus will be issued shortly, and all information can be obtained from Miss M. A. Willis, Secretary to the Fellowship of Medicine and Post-Graduate Association, 1, Wimpole-street, London, W.

The Psychological Laboratory.—The Committee for the management of the Cambridge University Diploma of Psychological Medicine announces that examinations for the diploma will be held for Part I. in October, 1920, and for Part II. in December, 1920. A course in preparation for these examinations will be held at the Cambridge Psychological Laboratory from July 19th to August 29th inclusive, and will be conducted as follows:—

Part I.—Psychology, with practical work, J. P. Lowson, M.A., M.D.; Anatomy and Physiology of the Nervous System, with practical work, E. D. Adrian, M.A., M.D.

Part II.—Abnormal Psychology, J. F. E. Prideaux, M.D.; Psychiatry, Lunacy Law, and Asylum Administration, M. A. Archdale, M.D., Superintendent of the Cambridge County Asylum.

The fees are: For Part I., £5 5*s.*; for Part II., £4 4*s.* Further information may be obtained from the Director of the Cambridge University Psychological Laboratory.

UNIVERSITY OF LIVERPOOL.—The diploma in Public Health has been awarded to Dr. A. J. W. Cunningham, Dr. R. W. Gemmell, and Dr. D. S. A. O'Keeffe.

KING'S COLLEGE (UNIVERSITY OF LONDON): PSYCHOLOGICAL DEPARTMENT.—A course of eight lectures on psycho-pathology will be delivered by Dr. William Brown, reader in psychology in the University of London, at King's College, Strand, W.C., on Mondays, at 5.30 P.M., beginning on Jan. 26th. Although not open to the general public, the lectures may be attended by medical students and qualified medical practitioners without fee or ticket.

KING'S COLLEGE HOSPITAL (UNIVERSITY OF LONDON): POST-GRADUATE INSTRUCTION IN SYPHILIS.—A course of lectures on syphilis will be given by various members of the staff of King's College Hospital during the ensuing year, commencing Jan. 30th. They will be given on Fridays, at 9.15 P.M., in the Lecture Theatre in the Medical School, and will be illustrated [illegible] far as possible by cases, demonstrations of technique, and by the epidiascope. Each branch will be dealt with by a member of the staff with special experience of the subject, and it is hoped that a complete presentment of modern teaching on syphilis, and especially of those aspects which are of interest to practitioners, will be given. Those taking the course can also attend, by arrangement, for clinical teaching and practical instruction. The fee for the course is £3 3*s.*, to be paid to the secretary of the Medical School, from whom all information can be obtained and the syllabus of the lectures.

THE SCIENTIFIC AND INDUSTRIAL RESEARCH DEPARTMENT.—The secretary of the department announces that the Research Association for the British Launderers' Industry has been approved by the department as complying with the conditions laid down in the Government scheme for the encouragement of industrial research. This concession is not surprising when regard is had to the fact that the business of the launderer is essentially a chemical one. The cleansing of dress fabrics by such materials as soaps, bleaches, reducing agents, and stain-removing solutions must be based on scientific lines if good results are to be got, rendering the processes involved effective economically while leaving the material uninjured. The question also of making dirty linen macroscopically and microscopically clean is clearly of sanitary importance. The association is to be registered [illegible] a non-profit-sharing company, the secretary of the committee engaged in its establishment being Mr. J. J. Stark, 162–5, Bank Chambers, 329, High Holborn, W.C. 2.

LITERARY INTELLIGENCE.—The sixth edition of Herman's "Difficult Labour," announced for publication by Messrs. Cassell and Co., has been brought up to date by Dr. Carlton Oldfield, honorary obstetric surgeon to the Leeds General Infirmary. Some enlargement has been found necessary and many new illustrations have been added.

FOUR lectures on the Animal Parasites affecting Man and the Diseases caused by Them will be delivered by Sir Robert Armstrong-Jones, at Gresham College, Basinghall-street, London, E.C., at 6 P.M., on Tuesday, Jan. 20th, and the three following days. Admission will be free and the lectures on Jan. 21st and 22nd will be illustrated by lantern slides.

ROYAL MICROSCOPICAL SOCIETY.—The annual meeting of the society will be held at 20, Hanover-square, London, W., on Wednesday next, Jan. 21st, at 8 P.M., to receive the annual report of the council and for the election of council and officers for the ensuing year. Mr. J. E. Barnard, the President, will deliver his address on the Present Status of Microscopy.

A STATE MEDICAL SERVICE.—The members of the Marylebone Division of the British Medical Association will discuss to-day (Friday, Jan. 16th), at 5 P.M., at the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, "The Future of the Medical Profession under a Salaried, Whole-time State Medical Service." The chair will be taken by Dr. C. O. Hawthorne, and the discussion will be opened by Professor Benjamin Moore, M.D., D.Sc., F.R.S. (of the State Medical Service Association), and Sir Wilmot Herringham, K.C.M.G., C.B.

PEOPLE'S LEAGUE OF HEALTH.—The supporters of the People's League of Health meet at Claridge's Hotel, Brook-street, W., on Tuesday next, Jan. 20th, at 3 P.M., to discuss and further the objects of the League. Among the speakers will be Miss Olga Nethersole, the original founder and honorary organiser of the League; Sir Alfred Fripp, K.C.V.O.; Mr. E. B. Turner, F.R.C.S., chairman of the Medical Committee of the National Council for Combating Venereal Disease; Miss Damer Dawson, O.B.E., chief officer of the Women's Police Service; and Mrs. Bramwell Booth. Lord Burnham will take the chair.

HIGH BIRTH-RATE IN NORWICH.—One of the results of the end of the war, due, of course, to the return of the soldiers, is manifested in the increasing birth-rate. There were 88 births registered in Norwich in the first week of January, corresponding to an annual rate of 37·8 per 1000, as compared with a rate of 12 per 1000 in the same period last year. The deaths at all ages during the week in question amounted to 35, corresponding to an annual death-rate of 15 per 1000, as compared with a rate of 19·3 per 1000 last year. If this satisfactory balance exists and can be maintained all over the kingdom, there should be no fear of any material decrease in our population.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—A quarterly meeting of the Council was held on Jan. 8th, Sir George H. Makins, the President, being in the chair.—Mr. Herbert S. Pendlebury was introduced, and having made a declaration in the terms of the oath prescribed by the Charter of 1800, was admitted [illegible] Member of the Court of Examiners.—The President reported that Sir Charters J. Symonds had consented to deliver the next Hunterian oration, and accordingly he declared him to be appointed Hunterian Orator for 1921.—The President reported that Mr. John Murray's term of office on the Court of Examiners would expire on Feb. 11th, and that the vacancy thus occasioned would be filled up at the Council meeting on Feb. 12th. Mr. Murray is eligible for re-election.—The President reported that no essay for the Jacksonian prize had been received.—The thanks of the Council were given to Mr. E. Muirhead Little for presenting to the museum a collection of skiagrams and photographs illustrating the pathology of stumps. The Council proceeded to the consideration of the report of the Committee on the annual report of the Council regarding the proceedings at the annual meeting of Fellows and Members in November. It was decided to appoint a committee to consider the question of the representation of Members on the Council.—Sir Charters J. Symonds was nominated a representative of the College on the Council of Queen Victoria's Jubilee Institute for Nurses for a period of three years from March 1st, 1920.—A letter was read from Sir D'Arcy Power, reporting his attendance as the representative of the College at the annual meeting of the Court of the University of Sheffield.—A letter was read from Mr. J. Herbert Parsons and Mr. M. S. Mayou, forwarding a copy of a memorandum drawn up by the Committee appointed by the Commissioner of Police of the Metropolis to consider the question of standards of sight requisite for licensed vehicle drivers, upon which Committee they were nominated by the College to serve.

KENT LOCAL MEDICAL AND PANEL COMMITTEES.—We have received from Messrs. Larking and Larking, clerks to the Committees, copies of circular letters sent out to panel practitioners in Kent. The letter, dated Jan. 10th, and signed by Dr. Frank Coke, medical secretary, requests the practitioner to sign an enclosed resignation from the Kent panel list, giving the usual statutory six weeks' notice. "Our negotiations with the Kent Insurance Committee enabled us," the letter runs, "to agree upon terms which we should have had no hesitation in advising practitioners to accept," but "the wishes of both the Kent Insurance Committee and of our Committees have been entirely ignored and overruled by the Ministry of Health." The letter was the outcome of a meeting of the Local Medical and Panel Committees held on Jan. 7th, when the following resolution was passed, 26 of those present voting for it and 1 abstaining:—

> "That the secretary be instructed to put into operation forthwith the Kent scheme of organisation for refusal of services under the Insurance Acts until the terms of service offered are satisfactory, and especially as a protest against (1) the legal disabilities; (2) the depreciation of capital value of practices; and (3) the hampering of efficient medical practice entailed by the New Regulation."

The chief provisions of the scheme referred to are as follows:—

> Firstly, that in no circumstances is there to be any refusal of treatment to any sick person. Secondly, that resignations are to be collected and placed in the hands of your Committees, but are not to be used until after a ballot of all those resigning. Thirdly, that previous to the final ballot being taken, a clear statement of all the facts with the names of those resigning shall be sent to all panel practitioners in each area. Finally, that in no case are resignations to be used unless your Committees are confident that they have sufficient resignations in any particular place or small district to affect the purpose at issue.

The letter concludes thus: "The capitation fee has not yet been fixed. Nevertheless, if the practitioner has not, by the middle of February, definitely notified his resignation from the panel, he will be held to have accepted both the new regulations and the old, and they will come into force on April 1st."

A COMPLIMENTARY luncheon is to be given to Sir Henry Gauvain by friends who wish to mark the honour recently conferred upon him in recognition of his work for the Cripples' Hospital and College at Alton. Sir William Treloar will preside.

ST. MARY'S HOSPITAL MEDICAL SCHOOL DINNER.—The annual dinner of the St. Mary's Hospital Medical School, postponed from last October, was held at the Connaught Rooms on Jan. 9th. Sir Almroth Wright was in the chair and some 150 past and present students attended. Among the guests present were Sir John Goodwin, Sir Bertrand Dawson, as he was styled, Sir Humphry Rolleston, Sir John MacAlister, and Sir StClair Thomson. It was the first dinner held since 1913 and was therefore even more in the nature of a reunion than usual; the shadow of the war was reflected in the speeches of the chairman and Sir John Broadbent, dean of the school, while Sir John Goodwin referred in glowing terms to the services of St. Mary's men in every theatre of war. In replying to the toast of "The Medical School," the dean spoke optimistically of its present position and future prospects. The school had been thrown open on equal terms to men and women, an experiment which had proved a success. The lack of adequate class-room and laboratory accommodation was being felt severely, and steps were being taken to improve the medical school buildings. Important advances had been made in the scientific work of the hospital; the various departments of pathology and bacteriology had been amalgamated to form one Institute of Pathology under the general direction of Sir Almroth Wright, and the heads of the various departments were being put upon the staff of the hospital. A scheme had been drawn up to establish teaching and research units in medicine and surgery, and to this end an affiliation had been carried out with the Paddington Green Children's Hospital, the Maida Vale Hospital for Nervous Diseases, and the Paddington Infirmary, so that the teaching facilities offered by these institutions were now available for St. Mary's students. This affiliation, quite apart from the opportunities it gave for the study of neurology and children's diseases, provided nearly 1000 beds for clinical teaching, and, in conjunction with the opportunities for scientific teaching and research given by the new Institute of Pathology, should establish St. Mary's as one of the most important institutions for medical education in London. Sir Bertrand Dawson paid a tribute to Sir Almroth Wright's scientific achievements, and in the course of his speech pointed out that the medical profession now occupied a more important position in the general community than ever before. He made an appeal to medical men to cease from worrying about detail and to concentrate on broad principles of work and policy.

THE new headquarters of the British Dental Association at 23, Russell-square, London, W.C., will be opened by Dr. Addison, the Minister of Health, on Friday next, Jan. 23rd, at 3.15 P.M.

THE annual dance of the University College Hospital Medical Society will be held at Princes Galleries on Wednesday, Feb. 11th, at 9 P.M. Tickets (£1 1s.) may be obtained from the Secretary.

CHELTENHAM REUNION DINNER.—A reunion dinner of the medical men of Cheltenham and district who had served with the R.A.M.C. was held on Jan. 10th at the Lansdown Hotel. Dr. J. Rupert Collins was in the chair, and among those present were Dr. Braine-Hartnell, Dr. Barret Cardew, Dr. Sanderson Clow, Dr. D. Clow, Dr. Conder, Dr. Cox, Dr. Lidderdale, Dr. Longridge, Dr. Macfie, Dr. Meyrick-Jones, Dr. Moore, Dr. O'Leary, Dr. Park, Dr. Peake, Dr. Pearson, Dr. Allman Powell, Dr. H. Powell, and Dr. Curtis Webb. The usual toasts were duly honoured and a most enjoyable evening was passed. It was unanimously decided that the dinner should be made an annual one.

GREAT NORTHERN CENTRAL HOSPITAL.—The King's concert for the patients of the Great Northern Central Hospital, Holloway, was held in the Islington Victoria Ward on Jan. 13th. The arrangements were made by the Ladies' Association of the Institution, the artists being Misses Lily Clare and May Windsor, Messrs. Rex Howard, Charles Conyers, and Norman Long. Lord Northampton, chairman of the hospital, expressed the thanks of the committee of management for the Royal interest in the institution, and mentioned that the expenses of the concert were being defrayed by the King. It was resolved to send the following telegram to His Majesty at Sandringham:—

> "The patients of the Great Northern Central Hospital humbly thank Your Majesty for the excellent entertainment provided this evening, and offer their humble duty on the occasion."

ST. THOMAS'S HOSPITAL OLD STUDENTS' DINNER.—At the annual dinner held after a break of five years, nearly 200 past students foregathered at the Connaught Rooms, London, to renew old friendships and to do honour to Sir George Makins, President of the Royal College of Surgeons, who occupied the chair. After the chairman had proposed success to the Hospital and Medical School in a few well-chosen words, dwelling on the exploits of the past and the hopes of the future, Sir Arthur Stanley replied, as the treasurer of two years' standing. Whatever the fate of the voluntary hospitals was to be, he intended that St. Thomas's should have a good run for its money, or, as Dr. Addison suggested later, for other people's money. Sir Cuthbert Wallace, who responded as dean of the Medical School, after enumerating the many honours gained by St. Thomas's men during the war, spoke with enthusiasm of the introduction of the professorial system into the school, the facilities for research which attended it, and the opportunity it offered of breaking down the inveterate insularity of the metropolitan medical schools. The war memorial was to take the form of a hostel designed to aid the collegiate life of the school. St. Thomas's, he suggested, might well be more conscious of its own worth and of the lamp which had been kept burning for a thousand years or more in Bermondsey and Southwark. Dr. Addison said that it did not pass the wit of man to devise some scheme whereby the State might help and receive help from the voluntary hospitals without destroying their character, and he did not fear for the finance of St. Thomas's in the hands of its determined, enlightened, and ruthless treasurer. He put in a special plea for scientific and laboratory equipment, and a proper payment of the expert staff. The evening closed with the proposal of the chairman's health by Mr. Samuel Osborn and the ovation which followed.

HOSPITAL ACCOMMODATION IN BIRMINGHAM.—A novel proposal concerning the organisation of hospitals administered by boards of guardians is being considered. Members of the Birmingham board of guardians have met members of the General and Queen's Hospitals to discuss proposals with regard to the future use of the Dudley Road and Selly Oak Infirmaries. The former building, with 1200 beds, was until recently the 2/1st Southern General Hospital and is now available again for civilian use. It is not anticipated that the whole of the accommodation at these two buildings, totalling 1650 beds, will be required for the purpose of a Poor-law infirmary, and a scheme of reconstruction applicable to post-war conditions is under consideration. At present there are more than 1000 patients on the waiting lists of the voluntary hospitals, and it is possible that such accommodation for medical and surgical patients may be made in the infirmaries as will relieve the pressure on the other hospitals. Such a proposal must necessarily have important bearings upon the future of voluntary hospitals and raise difficult questions such as the payment of medical staffs.

BRITISH FEDERATION OF MEDICAL AND ALLIED SOCIETIES.—Dr. Addison, Minister of Health, will receive a deputation from the Federation at 11.30 A.M. on Friday next, Jan. 23rd. The deputation desires to place before him certain aspects of the larger questions of the provision of efficient medical services for the community, and will be introduced by Sir W. Watson Cheyne, Bart., M.P., who will be accompanied by other medical Members of Parliament.

A thanksgiving service for the passing of the Nurses Registration Acts will, by the kindness of the Vicar, the Rev. H. R. L. Sheppard, be held at St. Martin's-in-the-Fields, on Friday next, Jan. 23rd, at 7.15 P.M. An address will be delivered by the Rev. A. H. R. Robinson, Mus. B. (Precentor), and during the singing of the hymn which follows an offertory will be collected. After defraying the expenses of the service the balance of the money will be given to the Trained Nurses Annuity Fund.

The Services.

ARMY MEDICAL SERVICE.

Major-Gen. H. Carr retires on retired pay.

Colonels from the half-pay list retiring on retired pay: G. T. Rawnsley, T. B. Beach.

Temp. Col. Sir H. J. Stiles (Bt. Lieut.-Col., R.A.M.C., T.F.) relinquishes his temporary commission on re-posting.

ROYAL ARMY MEDICAL CORPS.

Major F. E. Rowan-Robinson relinquishes the acting rank of Lieutenant-Colonel.

Temp. Major C. E. Ligertwood relinquishes the temporary rank of Lieutenant-Colonel on re-posting.

Capt. L. C. Hayes to be temporary Major whilst specially employed.

The undermentioned Captains relinquish the acting rank of Major: W. T. Hare, E. C. Lambkin, J. S. McCombe.

Capt. and Bt. Major J. D. Kidd to be acting Major.

Capt. P. H. Wells resigns his commission.

L. C. E. Murphy, late temporary Captain, to be temporary Captain.

Officers relinquishing their commissions:—Temporary Captains granted the rank of Major: D. C. Ogilvie, J. P. Davidson, R. B. Roe, F. H. Moxon, R. S. S. Statham, E. T. C. Milligan, J. W. McKinney, R. Jamison. Temporary Captains retaining the rank of Captain: C. Harris, A. C. MacKay, J. R. Stott, C. W. Macpherson, M. Sommerville, H. N. Crossley, W. A. Alexander, R. N. Thomson, W. Campbell, J. G. Lessey, M. Rust, T. M. Anderson, S. C. R. Flaxman, W. J. Symes, C. F. Davey, C. C. Harrison, A. G. Howson, J. F. Penman, M. H. Watney, A. P. Green, P. J. Montgomery, E. D. F. Hayes, C. Murphy, E. T. Jameson, E. G. D. Murray, R. R. K. Paton, C. A. O'Driscoll, K. D. Falconer, A. Gaston, W. J. Moir, A. R. H. Geyer, R. W. Miller, C. J. C. Macquarie, H. B. McCaskie, D. R. Adams. Temp. Lieut. J. A. Martin (retains the rank of Lieutenant).

SPECIAL RESERVE OF OFFICERS.

Capt. A. G. McColl relinquishes his commission and retains the rank of Captain.

Lieut. A. B. Grant to be Captain.

TERRITORIAL FORCE.

Capt. (acting Lieut.-Col.) H. N. Barnett relinquishes the acting rank of Lieutenant-Colonel on ceasing to be specially employed.

Capts. (acting Majors) G. B. Eadie, N. W. Kidston, and K. I. S. Smith relinquish the acting rank of Major on ceasing to be specially employed.

Capt. V. T. Ellwood is restored to the establishment.

Lieut. (temp. Capt.) W. L. H. Duckworth ceases to serve with the Cambridge University Contingent (Medical Unit), Senior Division, and relinquishes the temporary rank of Captain.

2nd Eastern General Hospital; Major F. G. Bushnell is restored to the establishment.

ROYAL AIR FORCE.

Medical Branch.—Flying Officers to be Flight Lieutenants: D. Cromie, J. B. Barnett, C. H. Young.

Squadron Leader E. G. R. Lithgow (Major, R.A.M.C.) relinquishes his temporary R.A.F. commission on return to Army duty.

Wing Commander J. St. J. Murphy (Surgeon Commander, R.N.) and Flight Lieut. E. Hefferman (Surgeon Lieutenant, R.N.) relinquish their temporary R.A.F. commissions on return to Naval duty.

The undermentioned are transferred to the unemployed list: Capts. J. Paxton, J. R. Adam, J. H. Cooke, A. B. Rooke, J. S. Dockrill; Lieut. J. Gorsky.

INDIA AND THE INDIAN MEDICAL SERVICE.

The following are appointed to civil employment from military duty: Major and Bt. Lieut.-Col. M. Mackelvie to be Civil Surgeon. Major H. B. Foster, Civil Surgeon. Major H. B. Steen, Civil Surgeon, but will continue to act as Surgeon Superintendent of the Presidency General Hospital, Calcutta. Major O. St. John Moss, Civil Surgeon, but will continue to hold his present appointment. Major F. A. F. Barnado, Civil Surgeon. Major R. E. Lloyd, Civil Surgeon. Lieut.-Col. W. H. E. Woodwright, Officiating Inspector-General, Civil Hospitals, Bengal, on being relieved reverts to Civil Surgeon, Bareilly. Capt. R. V. Clarke, R.A.M.C., has been appointed to hold Civil Medical Charge of Roorkee, in addition to his own duties. Major R. Kelsall is posted permanently under Burma Government. Miss Anne Siret to be Obstetric House Surgeon, King George's Medical College, Lucknow, as a temporary measure, vice Miss M. E. Glancy granted leave. The following officers have reverted to the Civil Department: Lieut.-Col. F. H. Watling and Major O. Berkeley Hill to Bihar and Orissa; Major H. A. Williams and Major J. Good to Burma; Major G. Fowler to the Central Provinces; Lieut.-Col. J. H. Hugo to Foreign and Political Department; Major W. S. Patton to Madras; Major S. R. Christophers to Central Research Institute, Kasauli; Lieut.-Col. B. R. Chatterton to Bihar and Orissa; Lieut.-Col. J. W. Grant and Lieut.-Col. L. J. M. Deas to Foreign and Political Department; Lieut.-Col. C. A. Gill to the Punjab; Major C. E. Palmers and Major J. E. Clements to the United Provinces; Lieut.-Col. H. Burden, Chief Medical Officer, Baluchistan, has been given one year's leave; Lieut.-Col. M. Curry to be Superintendent of the District Jail, Ferozepore; Lieut.-Col. H. Smith, C.I.E., Civil Surgeon, is posted to Amritzar on return from leave.

COMMISSIONS IN THE ARMY FOR DENTISTS.

The War Office is asking for the services of dental practitioners, including those who have already served, who are desirous of undertaking duty with the Army. Candidates with not less than a year's previous service will be commissioned to the rank of Captain, all others as Lieutenant. The term of engagement will be for 12 months or until no longer required, and the pay will be £600 per annum for Captains and £550 for Lieutenants, together with free rations, travelling allowances and expenses, kit, and outfit allowance of £30 if joining for the first time, and additional pay of £50 per annum when serving outside Europe. Candidates, who must be fit for service at home or abroad, should apply to the Secretary, War Office, A.M.D. (1), Cornwall House, Stamford-street, S.E. 1.

Communications, Letters, &c., to the Editor have been received from—

A.—Dr. F. S. Arnold, Berkhamsted; Sir R. Armstrong-Jones, Lond.

B.—Mr. F. Breckin, Cheam; Dr. J. Blomfield, Lond.; Board of Education, Lond.; Dr. H. S. Banks, Motherwell; British Federation of Medical and Allied Societies, Lond., Gen. Sec. of; Sir A. Bowlby, Lond.; Prof. A. E. Boycott, Lond.; Dr. N. Barnett, Bath; Dr. G. F. Barham, Woodford Green.

C.—Dr. E. L. Collis, Cardiff; Sir John Collie, Lond.; Mr. A. L. Candler, Exeter; Mr. H. Chaffer, Eastbourne; Cremation Society of England, Lond.; Messrs. Cassell and Co., Lond.; Dr. C. Chidell, Folkestone; Chicago School of Sanitary Instruction.

D.—Dr. G. H. Dart, Lond.; Dr. T. V. Dickinson, Ellel Grange; Messrs. Down Bros., Lond.; Dr. F. Dévé, Rouen; Messrs. W. Dawson and Sons, Lond.; Mr. E. M. Davies, Rochdale; Prof. L. Doncaster, Liverpool; Dr. H. G. Dixon, Lond.

E.—Prof. Dr. Engel, Dortmund; Dr. W. A. Evans, Keighley; Miss E. Evans, M.B., Cardiff.

F.—Factories, Chief Inspector of, Lond.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.

Thursday, Jan. 22nd.—3.30 p.m., Special General Meeting, the Prince of Wales having expressed his intention to attend for admission into the Society.—4.30 p.m., Ordinary Meeting. Papers (among others):—Mr. S. Marsh: On Alternating Current Electrolysis (communicated by Prof. E. H. Griffiths).—Mr. S. D. Carothers: Plane Strain. The Direct Determination of Stress (communicated by Prof. A. E. H. Love.)—Mr. F. Horton and Ann C. Davies: An Investigation of the Effects of Electron Collisions with Platinum and with Hydrogen, to ascertain whether the Production of Ionisation from Platinum is due to Occluded Hydrogen (communicated by Mr. C. T. R. Wilson).

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

Tuesday, Jan. 20th.

SPECIAL GENERAL MEETING OF FELLOWS: at 5 p.m.

To consider, and if approved to confirm, proposal by the Council that the following new By-law be enacted, viz.:—

"In view of certain anomalies and consequent hardships to Fellows and Members of Sections arising out of conditions resulting from the War, the Council is authorised to deal with all such questions at its discretion, the provisions of other By-laws notwithstanding, but such special power shall be limited to a fixed period, namely, from 1st January to the 31st December, 1920. If at the end of that period it shall seem desirable or necessary to continue the powers hereby granted they may be continued for another period not exceeding six months by vote of three-fourths of the Members of the Council present and voting at such Meeting of the Council called for the purpose of considering the question. At the end of the period or periods fixed, it shall be lawful to omit this temporary By-law from the By-laws of the Society."

To be followed immediately by a

GENERAL MEETING OF FELLOWS:

Ballot for Election to the Fellowship. (Names already circulated.)

Wednesday, Jan. 21st.

OCCASIONAL LECTURE: at 5 p.m.

Surgeon-Commander K. Digby Bell, R.N.: The Position of the Medical Profession with Regard to National Physical Education.

MEETINGS OF SECTIONS.

Tuesday, Jan. 20th.

THERAPEUTICS AND PHARMACOLOGY (Hon. Secretaries—Philip Hamill, Douglas Cow); at 4.30 p.m.

Discussion:

On "The Therapeutic Uses of Oxygen," to be opened by Mr. J. Barcroft, C.B.E., F.R.S.

Colonel Cummins, C.B., C.M.G., Dr. C. G. Douglas, Dr. J. S. Haldane, F.R.S., Dr. P. Hamill, Dr. G. H. Hunt, Dr. R. H. Peters, Dr. Ryle, Dr. F. Shufflebotham and Dr. G. H. Sowry will also speak.

PATHOLOGY (Hon. Secretaries—J. A. Murray, Cecil Price-Jones); at 8.30 p.m., to be held at the Imperial Cancer Research Laboratories, 8, Queen-square, W.C. 1.

Mr. W. H. Woglom: Industrial and Experimental Pitch Warts.

Mr. A. H. Drew: Oxidation Process in Normal Tissues and Cancer.

Mr. W. E. Gye and Dr. B. R. G. Russell: Conditions of Survival of Tumour Cells *in vitro*.

Dr. W. Cramer: Action of Uranium Salts on Tumour Cells.

Dr. J. A. Murray: Return-autologous Grafting of Tumours after Transplantation in Normal Animals.

Friday, Jan. 23rd.

STUDY OF DISEASE IN CHILDREN (Hon. Secretaries—E. A. Cockayne, H. C. Cameron, C. P. Lapage): at 4.30 p.m.

Exhibition of Cases.

EPIDEMIOLOGY AND STATE MEDICINE (Hon. Secretaries—William Butler, M. Greenwood): at 8.30 p.m.

Papers:

Dr. F. G. Crookshank: Principles of Epidemiology.

Dr. Cleland and Dr. Campbell: Epidemiology of Acute Encephalomyelitis.

Dinner will be provided at the Welbeck Palace Hotel at 7 p.m. (price 7*s.* 6*d.*). It is specially requested that those intending to dine will send names to Dr. M. Greenwood, Lister Institute, Chelsea, S.W. 1, not later than Wednesday, Jan. 21st.

TUBERCULOSIS SOCIETY, at the Rooms of the Medical Society, 11, Chandos-street, Cavendish-square, W.

Monday, Jan. 19th.—8 p.m., Paper:—Dr. Gauvain: Surgical Tuberculosis from the Point of View of the Tuberculosis Officer. Followed by a discussion. Ordinary Business Meeting of the Society will follow.

LONDON DERMATOLOGICAL SOCIETY, St. John's Hospital, 49, Leicester-square, W.C.

Tuesday, Jan. 20th.—4.30 p.m., Pathological Specimens. Cases sent for Consultation. Clinical Cases will be shown by Dr. J. L. Bunch, Dr. W. Griffith, Dr. E. J. D. Mitchell, Dr. S. Kapoor, Dr. Eva White, Dr. D. Vinrace, The President, Dr. W. K. Sibley, and Dr. P. J. Edmunds.

ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.

Wednesday, Jan. 21st.—4.30 p.m., Paper:—Mr. A. H. Powell: Ancient Cottages and Modern Requirements.

ROYAL MICROSCOPICAL SOCIETY, 20, Hanover-square, W.

Wednesday, Jan. 21st.—8 p.m., Annual Meeting. Annual Report of Council and Election of Council and Officers for the ensuing year. Presidential Address:—Mr. J. E. Barnard: The Present Status of Microscopy.

HARVEIAN SOCIETY, at the Medical Society's Rooms, 11, Chandos-street, Cavendish-square, W.

Thursday, Jan. 22nd.—8.15 p.m., Annual General Meeting.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

Six Hunterian Lectures on John Hunter's Observations and Discoveries in Anatomy and Surgery (illustrated by his specimens and preparations).

Monday, Jan. 19th.—5 p.m., Prof. A. Keith: I., His Contributions to Our Knowledge of the Heart and Blood-vessels.

Wednesday.—5 p.m., Prof. A. Keith: II., His Contributions to Our Knowledge of the Lungs and Pleuræ.

Friday.—5 p.m., Prof. A. Keith: III., His Contributions to Our Knowledge of the Alimentary System.

UNIVERSITY OF LONDON.

Advanced Lectures in Physiology to Students of the University and others interested in the subject.

A Course of Eight Lectures on the Regulation of Respiration will be given by Dr. M. S. Pembrey and Mr. J. H. Ryffel at Guy's Hospital, Borough, S.E.

Thursday, Jan. 22nd.—4.30 p.m., Lecture III.

LONDON HOSPITAL MEDICAL COLLEGE (University of London), Mile End, E.

A Course of Instruction on the Diseases of Children, open to Post-Graduates and to Students of the Hospital. (The lectures will be illustrated by lantern slides.)

Monday, Jan. 19th.—9.15 a.m., Lecture II.:—Dr. Thompson: Organic and Functional Nervous Diseases, Meningitis and Mental Deficiency. (At the Anatomical Theatre.)

Wednesday.—10 a.m., Clinical Demonstration:—Dr. Miller. (At the Children's Out-patient Department.)

Saturday.—10.15 a.m., Lecture III., Dr. Hutchison: General Diseases. (At the Anatomical Theatre.)

NATIONAL HOSPITAL FOR DISEASES OF THE HEART POST-GRADUATE COURSE, Westmoreland-street, W.

Monday, Jan. 19th.—11 a.m., Out-patients: Dr. Goodall. 2 p.m. In-patients: Dr. Moon.

Tuesday.—2 p.m., Out-patients: Dr. R. Wells. 3 p.m., In-patients: Dr. Gibbes.

Wednesday.—2 p.m., Out-patients: Dr. Moon. 5.30 p.m., Lecture:—Dr. R. Wells: Aortic Disease.

Thursday.—10 a.m., In-patients: Dr. Hamill: 2 p.m., Out-patients: Dr. Price.

Friday.—2 p.m., Out-patients: Dr. Gibbes. 2.30 p.m., In-patients: Dr. Wells.

Saturday.—10.30 a.m., In-patients: Dr. Hamill.

ROYAL INSTITUTE OF PUBLIC HEALTH, at Poplar Dispensary for the Prevention of Consumption, 135, Bow-road, E.

Special Course of Lectures and Demonstrations on Tuberculosis for Medical Men and Women qualifying to become Tuberculosis Officers, General Practitioners, and others. Bacteriological Demonstrations will be given in the Laboratories of the Institute, and visits arranged to Sanatoriums, Tuberculosis Dispensaries, &c.

Thursday, Jan. 22nd.—5 p.m., Lecture II.:—Dr. T. D. Lister: A Practical Demonstration of the Work of a Tuberculosis Department at Poplar.

GRESHAM COLLEGE, Basinghall-street, E.C.

Tuesday, Jan. 20th, Wednesday, Thursday and Friday.—6 p.m., Lectures:—Sir Robert Armstrong-Jones: The Animal Parasites affecting Man, and the Diseases caused by them (illustrated by lantern slides).

UNIVERSITY OF SHEFFIELD—FACULTY OF MEDICINE POST-GRADUATE DEMONSTRATIONS, at the Sheffield Royal Hospital.

Monday, Jan. 19th.—3.30 p.m.; Dr. Nutt: Demonstration of X Ray Apparatus.

Tuesday.—4 p.m., Dr. Hay: Methods of Examination of Eye.

Wednesday.—3.30 p.m., Dr. Wilkinson: Common Forms of Sore Throat.

Thursday.—3.30 p.m., Dr. Skinner: General Considerations in Dermatology.

Friday.—4 p.m., Dr. Hay: Methods of Examination of Eye (continued).

UNIVERSITY OF BIRMINGHAM—FACULTY OF MEDICINE, in the Anatomical Theatre, Edmund-street, Birmingham.

Post-Graduate Course of Lectures on Venereal Disease:—

Wednesday, Jan. 21st.—4.15 p.m., Mr. B. Ward: Gonorrhœa in the Male. (Lecture I.)

MANCHESTER ROYAL INFIRMARY POST-GRADUATE CLINIC.

Tuesday, Jan. 20th.—4.30 p.m., Lecture:—Dr. A. Ramsbottom: Chorea.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, W.C. 1.

MEDICAL SCHOOL.

Monday, Jan. 26th.—2–3.30 p.m., Out-patient Clinic: Dr. Collier. 3.30 p.m., Dr. S. A. Kinnier Wilson: Examination of Nervous System and Interpretation of Physical Signs. III.

Tuesday, Jan. 27th.—2–3.30 p.m., Out-patient Clinic: Dr. Grainger Stewart. 3.30 p.m., Ward Cases: Dr. Risien Russell.

Wednesday, Jan. 28th.—2 p.m., Mr. Scott: Auditory Vertigo and Forced Movements. 3.30 p.m., Dr. Greenfield: Pathological Demonstration.

Thursday, Jan. 29th.—2–3.30 p.m., Out-patient Clinic: Dr. Farquhar Buzzard. 3.30 p.m., Dr. S. A. Kinnier Wilson: Examination of Nervous System and Interpretation of Physical Signs. IV.

Friday, Jan. 30th.—2–3.30 p.m., Out-patient Clinic: Dr. Gordon Holmes. 3.30 p.m., Ward Cases: Dr. Tooth.

Saturday, Jan. 31st.—9 a.m., Surgical Operations.

Fee for Post-Graduate Course £7 7*s.* C. M. Hinds Howell, Dean.

Appointments.

Everett, H. F., L.R.C.P. & S. Edin., L.F.P.S.G., has been appointed Certifying Surgeon under the Factory and Workshop Acts for Hadleigh.

Hutt, C. V., M.D., B.C. Camb., D.P.H. Oxon., Medical Officer of Health for Richmond, Surrey.

Kadinsky, Z. S., M.R.C.S., L.R.C.P. Lond., Surgical Registrar to the Westminster Hospital.

Smith, Edwin, M.D. Lond., Barrister-at-law, Deputy Coroner for Westminster and S.W. London District.

Vacancies.

For further information refer to the advertisement columns.

Bedford County Hospital.—H.S. and H.P. £175 and £150 respectively.

Bermondsey Medical Mission for Women and Children.—Female Res. Asst. M.O. £200.

Birkenhead Borough Hospital.—Two Hon. Asst. M.O.'s.

Birkenhead Union.—Asst. Res. M.O. £300.

Birmingham Children's Hospital.—P. to Out-patients and S.

Birmingham City Mental Hospital, Rubery Hill, near Birmingham.—First and Second Asst. M.O.'s. £500 and £400.

Birmingham, City Fever Hospital, Little Bromwich.—Asst. M.O. £300.

Birmingham General Hospital.—Clin. Path. £600.

Bristol, Beach House Estate Sanatorium.—Res. Supt. M.O. £800.

Bristol Royal Infirmary.—Clinical Pathologist. £250.

Bristol University.—Demonstrator of Path. £200.

Bury Infirmary, Lancs.—Jun. H.S. £150.

Capetown, City of.—Female Asst. to Health Dept. £650.

Cape Town University, Faculty of Medicine.—Chair of Bio-Chemistry. £800

Cardiff, King Edward VII. Hospital.—H.S. and H.P. £200.

Carlisle, Cumberland and Westmorland Mental Hospital, Garlands.—Jun. Asst. M.O. £350.

Derby, Derbyshire Royal Infirmary.—H.P. £200.

Derbyshire Education Committee.—Sch. M.O. £500.

Doncaster Royal Infirmary and Dispensary.—Asst. H.S. £200–£225.

Dorchester, Dorset County Council Education Committee.—School Dentists. £400.

Dudley, Guest Hospital and Eye Infirmary.—Vacancy on Hon. Surg. Staff. Also two Hon. P.'s.

Edinburgh, Scottish Board of Health.—M.O.'s.

Elizabeth Garrett Anderson Hospital, Euston-road.—Jun. Asst. P., Path., Asst. Path. Also Clin. Asst. £1 1s. per attendance.

Enham Village Centre, Andover, Hants.—Asst. Med. Direct. £600–£700. Neuro. M.O., £350.

Gilbert and Ellice Islands Colony and British Solomon Islands Protectorate.—Sen. M.O.'s. £600 each.

Gold Coast and Sierra Leone.—Dent. S. £500.

Great Northern Central Hospital, Holloway, London, N.—Two P.'s. Also Dental S.

Greenwich Union Infirmary, Vanbrugh Hill, East Greenwich, S.E.—Asst. Med. Supt. £300.

Hartlepool Union.—Asst. Res. M.O. £350.

Herefordshire General Hospital.—H.S. £200.

Hospital for Consumption and Diseases of the Chest, Brompton, S.W.—H.P. 30 guineas.

Hospital for Sick Children, Great Ormond-street, London, W.C.—H.S. £50.

Hull Royal Infirmary.—H.P. £200.

Kensington Tuberculosis Dispensary, 119, Ladbroke-grove, W.—M.O. £500.

King's College Hospital, Denmark-hill, S.E.—M.O. to Gonorr. Dept.

King's Lynn, West Norfolk and King's Lynn Hospital.—H.S. £150.

Leamington Spa, Borough of.—M.O.H. £650.

Lewes, East Sussex County Council Education Committee.—Jun. Asst. Sch. M.O. £450.

Lincoln County Hospital.—Junior H.S. £200.

Lindsey County Council.—Asst. Tuberc. O. and Asst. Sch. M.O. £450.

Liverpool, County Asylum, Rainhill.—Asst. M.O.'s. £300.

Liverpool Stanley Hospital.—H.P. and S. £150 each.

London Fever Hospital, Islington, N.—Locum Tenens Asst. M.O £7 7s. per week.

London Temperance Hospital, Hampstead-rd., N.W.—Anæsth. 25 gns.

Maidstone, West Kent General Hospital.—H.P. £200.

Manchester, Ancoats Hospital.—H.P. £150.

Manchester, Whitworth Park Hospital.—H.S. £100.

Metropolitan Hospital, Kingsland-road, E.—Asst. P.

Middlesbrough Education Committee.—Asst. Sch. M.O. £500.

Middlesex County Council.—Temp. Tuberc. M.O. £600.

Miller General Hospital for South-East London, Greenwich-road, S.E.—Res. Cas. O. Also H.S. £100.

Natal Provincial Administration.—Med. Inspect. and Asst. Med. Inspect. of Schools. £800 and £600.

Newcastle-upon-Tyne, Hospital for Sick Children.—Junior Res. M.O. £200.

Newcastle-upon-Tyne, Royal Victoria Infirmary.—Medical and Hon. Surg. Registrars.

New Zealand, Auckland Hospital.—Bact. and Path. £900.

Norwich City.—Asst. M.O.H. £300.

Paddington Green Children's Hospital, London, W.—S. to Eye Dept., P. to Skin Dept., and P. to Out-patients.

Plymouth, South Devon and East Cornwall Hospital.—H.S. £200.

Prince of Wales's General Hospital, Tottenham, N.—Hon. Asst. P.

Queen Mary's Hospital for the East End, Stratford, E.—Hon. S.

Royal Free Hospital, Gray's Inn-road, W.C.—Asst. M.O.'s in Venereal Diseases (Female) Dept. £250 and £150 respectively. Female Res. Obst. O. (£150), Res. Obst. H.S. (£50), Res. Obst. Asst. (£150).

St. Helens, Lancs, The Pilkington Special Hospital.—Asst. £500.

St. Mary's Hospital, Paddington.—First Asst. Pathol. £500.

Salford Royal Hospital.—Cas. H.S. £150.

Salisbury Municipality, Rhodesia, S.A.—M.O.H. £600

Scarborough Education Committee.—Sch. Dent. S. £250.

Seamen's Hospital Society, Hospital for Tropical Diseases, Endsleigh Gardens, N.W.—Med. Supt. £400.

Sheffield City Education Committee.—Asst. Sch. M.O. £450. Sch. Dental S. £400.

Sheffield Royal Infirmary.—Asst. H.P. and H.S. £150 each.

Sheffield University.—Demonstrator in Path. and Bact.

South London Hospital for Women, South Side, Clapham Common, S.W.—Female H.S. £100. Female Clin. Assts.

Stannington (Northumberland) Children's Sanatorium. — Res Female M.O. £250.

Straits Settlements.—Res. M.O. £840.

Straits Settlements and Federated Malay States.—M.O.'s.

Swansea County Borough.—Asst. M.O.'s. £600 and £500.

Swindon, Borough of.—Asst. M.O.H. £500.

University of London, South Kensington.—External Examiners.

Ventnor, Isle of Wight, Royal National Hospital for Consumption and Diseases of the Chest.—Asst. Res. M.O. £300.

Wakefield, Clayton Hospital.—Jun. H.S. £150.

Wakefield, West Riding County Council.—School Oculist. £550.

Westminster Hospital, Broad Sanctuary, S.W.—Asst. P. Also Two Hon. Administrators of Anæsth.

Whittingham County Asylum, Preston, Lancs.—Asst. M.O. £420.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Abergele, Buckie, Castle Hedingham, Clogher, Hastings, Hoylake, Leicester (East), Leyland, Nelson, Northallerton, Okehampton, and Wakefield.

Births, Marriages, and Deaths.

BIRTHS.

BRUNTON.—On Jan. 12th, at Purey Cust Nursing Home, York, to Lucy M. Brunton, M.B., wife of G. L. Brunton, M.D.—a son.

DICK.—On Jan. 10th, at a nursing home, Sevenoaks, the wife of R. J. Dick, M.D., of a son.

READE.—On Jan. 12th, at 35, Criffel-avenue, Streatham-hill, S.W. 2, Violet Reade, M.R.C.S., L.R.C.P., wife of Arthur G. L. Reade, O.B.E., Surgeon-Lieutenant R.N.V.R., of a son.

MARRIAGES.

WIRGMAN—STIVEN.—On Jan. 6th, at St. Mary Abbot's, Kensington, Charles Wynn Wirgman, M.D., F.R.C.S., to Beryl Annie Mabut Stiven, youngest daughter of the late E. W. F. Stiven, M.D., and Mrs. Stiven, of Inverness-gardens, W.

RELTON—SINTON.—On Jan. 8th, at the Parish Church, Harpenden, Charles Duncan Relton, M.B., B.S., Captain, R.A.M.C. (T.F.), to Grace Agnes, elder daughter of Mr. and Mrs. James Sinton, of Wynyates, Harpenden, Herts.

DEATHS.

BERNAYS.—On Jan. 6th, suddenly, at the Royal Victoria Hospital, Dover, Charles Murchison Bernays, M.R.C.S., L.R.C.P. (late R.A.M.C.), aged 39.

DAUNT.—On Jan. 6th, at Hastings, Dr. Wm. Daunt, aged 51.

HAMERTON.—On Jan. 11th, at Russell-square, after four days' illness from pneumonia, George Albert Hamerton, M.D., F.R.C.S.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

TWO EAST-END HOSPITAL APPEALS.

THE Special Appeal Committee of the Queen's Hospital for Children, Hackney-road, E., points out that this hospital will be compelled to close two wards containing 62 beds within three months unless funds can be obtained to pay off the deficit. The closing of the wards would deprive 800 little invalids from the poorest parts of London of the medical and surgical treatment which is afforded annually. The appeal is signed by, among others, the Earl of Shaftesbury, the Duke of Newcastle, the Bishop of London, the Chief Rabbi, and Lord William Cecil. The institution is over £10,000 in debt, and an additional £5000 per annum is required if the hospital is to be kept at its pre-war standard. At least 40,000 mothers take their children there in sickness and accident during the year, the attendances in the casualty and out-patient departments numbering over 10,000, and the demands on the 170 beds are always most pressing. Cheques, which should be made payable to the Queen's Hospital for Children and crossed "Barclay's Bank," should be sent to the secretary at the hospital, Hackney-road, Bethnal Green, E. 2.

At a "victory" dinner on behalf of Queen Mary's Hospital for the East End (incorporating the West Ham and Eastern General Hospital), held at Liverpool-street Hotel on Jan. 8th, the chairman, Mr. C. E. Leo Lyle, M.P., said that there was an immediate need for more beds. The local War Memorial Fund had provided £30,000 for extensions, but an increased annual income was needed for maintenance. A new nurses' home which was required would cost £30,000. A friend had given £10,000 for a maternity wing, but an additional £10,000 was required, together with a similar sum for extending the out-patient department. During the evening subscriptions were announced amounting to £5000 towards an appeal for £10,000 on behalf of the general fund.

THE HUMAN BELLOWS.

A CORRESPONDENT writes calling our attention to the demand made upon private nurses by their patients to blow up air-cushions by applying their mouth to the valve, and suggests that this dirty and obviously dangerous habit has been forced upon nurses by the omission on the part of the makers of air-cushions to supply any means of inflating them. We entirely agree with our correspondent that no nurse should be asked to put her mouth directly to a valve which may have been soiled by the patient or infected by a previous blower. But we note that at least one instrument-maker supplies a small bellows for cushions and pillows, and houses must now be few and far between where a bicycle pump would not be available for the purpose. It is, of course, open to any nurse, who does not object in principle to act as a bellows, to use a piece of indiarubber-tubing as an adaptor, sterilising the tubing, or, at all events, keeping it for her own particular use.

SURVIVAL OF QUADRUPLETS.

To the Editor of THE LANCET.

SIR,—Authentic instances of quadruplets being very rare (THE LANCET, Dec. 13th and 20th last), the case, as follows, which occurred in the practice of my late father—Dr. John Vinrace, of Birmingham—may be of interest. The mother was a primipara, aged 18, and single, and within about two hours gave birth to quadruplets at full time or nearly so. Two were born alive, but died within the day, and of the two born dead one was a monster (preserved in Queen's College, Birmingham). Subsequently the couple married and three or four normal pregnancies ensued, but no further plural birth.

I am, Sir, yours faithfully,
DENNIS VINRACE.

Gower-street, W.C., Jan. 13th, 1920.

METRIC PRESCRIBING.

To the Editor of THE LANCET.

SIR,—Please permit one who has had many years' experience in metric prescribing to offer a few suggestions to those who use or may contemplate using the same in lieu of the old and now obsolete imperial system.

(1) In prescribing, adopt the continental custom of placing the denomination instead of the decimal point between the integer and fraction. For instance, 8 g. 5 instead of 8·5 g., and 2 cg. 5 instead of 2·5 cg. By acting thus we write the amount as it is spoken. In decimal-using countries no one would say "eight point five grammes" any more than they would say "eight point five francs," but "eight grammes five" and "eight francs fifty."

(2) Fluid quantities under half a mil. are prescribed in drops.

(3) In dealing with small weights—i.e., under a gramme—the centigramme denomination will be generally found most convenient, and will not require so many figures as if expressed in grammes. But it is advisable to avoid, if possible, mixing grammes and centigrammes in the same prescription, as changing the denomination disturbs continuity of thought as conveyed by the vertical line of figures.

(4) Decigrammes and decimils. are only academical, and are not used in practice.

(5) It will be found more convenient to order 10 pills or powders rather than 12, as the calculations required can then be made by, mentally or otherwise, moving the point. But 12 may be ordered by the simple addition of a sixth to each quantity.

(6) For small doses, or where exactitude in dose is called for, as imperial equivalents, the gramme may be taken as 15½ grains, the millilitre (or c.cm.) as 17 minims (actually 16 min. 95). As metric equivalent the grain may be taken as 6 cg. 5 (actually 6 cg. 48). For larger doses, where a few grains more or less is of no consequence, the gramme and the mil. may be taken as equivalents. For very minute doses, as, for instance, for hypodermic use, to convert 1/10 and 1/100 to metric we move the point one or two places to the left; thus we get 0 cg. 65 and 0 cg. 065 (or, using the milligramme denomination, 6 mg. 5 and 0 mg. 65). Intermediate quantities are simply a matter of ordinary calculation.

(7) In prescribing a mixture for an adult, by taking the gramme and mil. as equivalent to 16 grains and 16 minims, which are near enough approximates, an 8-oz. bottle containing 16 doses suits our purpose, for by it we can transpose grains and minims to grammes and mils. at once, without any calculation. For instance, if we wish to order 10 gr. or 10 min. doses, in an 8-oz. mixture, we should prescribe 10 g. or 10 mils. respectively. In a 6-oz. mixture (of 12 doses) we should prescribe three-quarters of these amounts—namely, 7 g. 5 or 7 ml. 5, and for a 3-oz. mixture half, and so on from size to size. When prescribing for infants we choose a 2-oz. mixture of 56 mils. for the same reason because of its containing 16 teaspoonsful. If we wish to order, say, ½-min. doses of vin. ipec., we should prescribe for a 2-oz. mixture 8 drops.

(8) The approximate sizes of English bottles as at present made are: 1 oz. = 28 mils.; 2 oz. = 56 mils.; 3 oz. = 85 mils.; 4 oz. = 113 mils.; 6 oz. = 170 mils.; 8 oz. = 227 mils.; 10 oz. = 284 mils.; 12 oz. = 341 mils. These figures are given without their fractions, which, ranging from 5 to 10 drops, need only be treated as negligible quantities.

I am, Sir, yours faithfully,
W. WRIGHT HARDWICKE, M.D.

Coulson-street, S.W., Jan. 12th, 1920.

WANTED—AN APPOINTMENT.

To the Editor of THE LANCET.

SIR,—Undoubtedly the subject of this letter might well be expected to make her wants known through the advertisement columns, but I am hoping that my knowledge of her circumstances will gain her the advantage of the insertion of this letter.

An Englishwoman, widow of an American physician, 42 years of age, highly educated in England and on the Continent, holding the best certificates in foreign languages, and speaking French, Italian, and German, requires a resident or non-resident appointment to assist a medical man in any way. She has literary experience, she has managed the business and secretarial side of her late husband's work, who was a specialist in nervous diseases, and she has excellent references.

I am, with anticipatory thanks,
Yours faithfully,
M.D.

THE United States Public Health Service have issued a notice that *B. tularense*, an organism isolated by McCoy and Chapin from rodents suffering from a disease resembling plague, also infects man. It has been found by Dr. Francis that "deer-fly fever," a disease which occurs in rural districts in Utah and which causes fever and inflammation of glands, is due to the organism.

WE are asked to state that the "Central Welfare Supervisors Association" no longer exists as such, but has amalgamated with two other welfare workers' societies to form the "Welfare Workers' Institute," of which the general secretary is Miss E. B. Voysey, B.A., and the address 11, Adam-street, London, W.C. 2. A monthly magazine is to be issued by the institute dealing with all matters relating to industrial welfare.

A Lecture

ON

'ULMONARY AND OTHER FORMS OF TUBERCULOSIS:

OME FACTS, THEORIES, AND HYPOTHESES.

Delivered at the Brompton Hospital,

Y H. BATTY SHAW, M.D. LOND., F.R.C.P. LOND.,
PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL, AND TO THE BROMPTON HOSPITAL FOR DISEASES OF THE CHEST.

GENTLEMEN,—In this lecture it is proposed to onsider some of the truths connected with tuberulosis, to pursue them to their logical end, and lso to consider various theories and hypotheses onnected with the subject. By a fact we mean a ruth—a reality—something which may be tested, n this direction and that, and always found to be he same. On such facts progress can be made afely. It is necessary, however, to remember that hypothesis is only a hypothesis—it is only a upposition. It is possible to advance our nowledge, working on a hypothesis, even when it s shown that the hypothesis was not in accordance vith truth. Sometimes the importance of facts licited by working on a hypothesis is so great that he hypothesis almost rises to the dignity of a fact. t is very desirable to keep clearly separated facts nd hypotheses. A theory has been defined as an xplanation of natural phenomena founded on facts nown to be true from evidence independent of hose phenomena or appearances. As in the case f a hypothesis, a theory which turns out to be vrong may lead to the discovery of many facts which therwise would not be discovered. We know that he atomic theory is wrong; but what an immense mount of discovery and progress have been made, cting on the belief that the atomic theory was orrect. Not all wrongly conceived hypotheses nd theories have led to progress: some of them ave actually prevented progress, so that when new ypotheses and theories are put forward they hould be very carefully tested by skilled critics, nd inquiries based upon their acceptance should be carefully planned.

THE TUBERCLE BACILLUS.

The most cardinal fact connected with tuberculosis is that the *B. tuberculosis* causes tuberculosis of the body, especially of the lungs, producing (*a*) miliary tuberculosis; (*b*) massive or confluent pneumonia; and (*c*) the development of fibrosis, as seen in the familiar scarred apices of the lungs, if the tuberculosis of the lung is mastered. The discovery of the pathogenicity of the tubercle bacillus has never been gainsaid; this fact, which Koch published, has been confirmed over and over again.

It has been assumed that the *B. tuberculosis* is responsible for what we call consumption—that is to say, of the cases of destructive lung disease of a subacute or chronic character which are known to every family practitioner. A support for this hypothesis is that tubercle bacilli are so often present in the sputum derived from such patients. But if the sputum is studied to find what other organisms are present, it is well known to contain harmless saprophytes, several other pathogenic organisms, and even putrefactive organisms. One of the most common pathogenic organisms is the staphylococcus; there is also the streptococcus and the pneumococcus—all organisms capable of producing pus. The tubercle bacillus in its most characteristic lesions produces a very special cellular reaction which undergoes a change to form the so-called grey or white tubercle, and this may be surrounded by fibrous-tissue reaction, or the whole mass be converted into a caseated or calcareous mass. It does not seem that the tubercle bacillus is a pus-producer like the ordinary pyogenic organism. It is a much more reasonable hypothesis to believe that the pus of the expectoration is due to other organisms than the tubercle bacillus. We know on extensive observation how frequently the animal body may be actually infected by the tubercle bacillus, and yet succeed in reducing the harmfulness of the latter to nil.

We may indulge in a further hypothesis, and believe that a lung which is already damaged by the existence of tubercle bacilli is no longer able to resist attacks made by the other organisms which are found in the sputum of a tuberculous subject. This hypothesis is almost raised to the dignity of a theory when it is recalled how frequently tuberculosis of the lungs seems to date from an attack of bronchial catarrh. Some would consider such a theory an established fact; but before it may be considered such it is necessary to know by control the number of cases in which tuberculosis seems to date from a certain period which was not marked by the existence of bronchial catarrh.

HÆMOPTYSIS IN TUBERCULOSIS.

A second fact is one which has been confirmed over and over again—hæmoptysis is very frequently followed, after a long or short interval, by pulmonary tuberculosis, or by consumption. It is a well-known fact that the expectoration at the time of the hæmoptysis may reveal no tubercle bacilli. Are we right in supposing that every case of hæmoptysis, in which, say, half a drachm, or a drachm of blood, or more, is coughed up during a day on two or three successive days, is a case of pulmonary tuberculosis or of consumption? It is quite evident that before we make a diagnosis that this is the sort of hæmoptysis which leads to pulmonary tuberculosis or to consumption we must exclude the ordinary causes of what is known as pseudohæmoptysis. If the hæmoptysis amounts to mere streakiness, or staining of the sputum, is occasional, and has been observed over long periods, amounting to months, we are justified in hesitating in believing that such hæmoptysis means as surely ultimate consumption or pulmonary tuberculosis as if it had been a more copious bleeding.

Pathological studies show us that the *B. tuberculosis* invading an artery is more inclined to produce thrombosis, following endarteritis, with occlusion of the vessel, than to cause suppuration in the walls of the vessel with weakening of it, and the formation of an aneurysm or rupture. In other words, we may suppose that hæmoptysis reduced to its residual value as a symptom is also an expression of the mixed infection which occurs in the lungs, already the seat of tuberculosis. Can this hypothesis be exalted into a fact by appeals to experimental research? So far as I know, this has not been done; but we do know that the course of tuberculosis of the lungs is slower and more benign in people who live in warm, dry climates, or in country districts, or in elevated areas, and we presume that this is due to the fact that there is less catarrh of the bronchi in these circumstances than in opposite ones. Moreover, we meet with very severe hæmoptysis in lung conditions which are not due to the *B. tuberculosis*—e.g., in some cases of pneumonia, in bronchiectasis, in abscess, and in gangrene of the lung. We thus find that there is considerable support for the theory that the destruction of lung tissue and of arterial walls in consumption is more a direct result of mixed infection than of a pure tuberculous infection.

THE APICAL CAVITY IN DIAGNOSIS.

Those who have to do with the examination of many chests state that quite a considerable number of cases occur in which cavities are found at the apices of the lobes of the lung; this is a well-established fact. But now we have to admit that some very sweeping hypotheses have been built upon this fact. One is that such cavities occurring at the apices of lobes indicate that the lungs are certainly the seat of pulmonary tuberculosis, which has given rise to consumption. The result is that the mere existence of a cavity or cavities justifies many physicians in diagnosing consumption. Other observers, since the presence of tubercle bacilli in the sputum, even after repeated examinations, cannot be established in the patients revealing these cavities, persist in a still further hypothesis that tuberculosis was the origin of the cavity formation, and that mere cavity formation was dependent upon a prior evacuation of all the dead tissue and of the tubercle bacilli which caused the death of the tissue. The position taken up by these observers appears unassailable, and the frequency with which consumption is accompanied by excavation of the apices raises these hypotheses to the dignity of theories. In former days, before the use of the microscope, or of inoculation experiments to prove tuberculosis of the lungs, was introduced, no doubt a great amount of suffering was alleviated by treating all patients revealing apical cavities as consumptives.

Modern research shows that the theory was too sweeping, and it is an acknowledged fact now that cavities may form in any part of the lungs, entirely independently of tuberculosis. Cavity formation in the lung may quite well be immediately dependent upon the colliquative processes caused by mixed infection, rather than upon the direct effect produced by the tubercle bacillus.

UNIVERSALITY OF INFECTION IN THE YOUNG.

Another fact which is so well known to many of us that we have become over-familiar with it, is that a very large number of children—indeed, probably *all* children—living under the conditions of civilisation, are infected by the *B. tuberculosis.* They do not necessarily suffer from the infection, because the lesions produced do not materially disturb the bodily functions. The children, in a sense, though not the true sense, of course, are "carriers" of the tubercle bacillus. In many cases they are destroyed by tuberculosis, and we know that some of the most acute and classical forms of pure tuberculosis—namely, miliary tuberculosis, occur in childhood. It looks as if the joint disease of childhood, tuberculous peritonitis and the tuberculous infections of the intestinal tract, are due to the operations of the bovine form of the *B. tuberculosis.* But we must not forget the fact that children are not only susceptible to the bovine form of tuberculosis taken in with food, but that they are equally liable as adults to take the human tubercle bacillus into their systems through the respiratory tract. And while we are discussing this subject we cannot but ask the very vital question as to the relationships of the bovine to the human form of the tubercle bacillus. I am not capable of answering the question whether these two organisms are two absolutely different types, or whether the bovine tubercle bacillus, by long residence in the human body, may not assume the cultural morphological and pathogenic characters of the human tubercle bacillus. Contemporary bacteriology admits that this question is not settled; it is quite an open one. It remains a fact, then, that children are universally infected by the tubercle bacillus of the human form, and in a certain proportion of them, varying in amount, according to different observers, are also infected with the bovine tubercle bacillus. One observation points to the universal infection by this organism, because a tuberculin reaction was found in every adult examined, and it is a common observation in the post-mortem room to see active or involuted tuberculosis in such a large number of cases who have died of some other malady. If my remarks sound over-emphasised upon this widely accepted fact (amongst pathologists) of the universal infection with the tubercle bacillus of human beings living in conditions of civilisation, I must ask you to make allowances on the ground that I think that the subject of tuberculosis has become popularised too much, or should I say has been only partially popularised. It is more palatable to a lay audience to listen to the accounts of the marvellous cures which have come as a result of this, that, or the other treatment. It is not at all palatable, and lay men and women would not be tempted to join associations for the study of this disease if they were told the whole truth. Even the business men who help to work our hospitals are much more susceptible to the stimulating effects of the publication of alleged cures than of the failures. Nor, if I may be allowed to say so to you, do I think you gentlemen, when you leave our hospitals and our post-mortem rooms and accept positions as tuberculosis officers, take sufficient pains to keep before you what pathology has taught you. Like you, I am not a pathologist; but after suffering very much disappointment following upon the small results, if any, obtained by sanatorium treatment, by the dispensary method, by so-called notification, I am asking myself and you to-day to get rid of enthusiasm and look at some bare facts.

To continue with my immediate subject, let us consider how the theory or fact of universal infection with the tubercle bacillus is borne out by some common experiences. We have all had the experience of treating a child for tuberculous glands and later on finding that child, in the adult stage, suffering from pulmonary tuberculosis. An out-patient appeared here not long ago limping on one leg, the opposite knee partially flexed and ankylosed. I recognised his face and recalled to him the fact that 16 years ago I had helped as a dresser to look after his tuberculous right knee. I also recalled to myself being sent by my surgical chief to find a physician to report on the condition of this patient's chest. The physician saw the case and told me he could find no signs of active tuberculosis, but, being a sound student of medicine, he would not commit himself and say there was no active tuberculosis in the lungs. When I examined the patient recently he had fully developed consumption. It seems to me reasonable to think that the tuberculosis which expressed itself in the knee 16 years ago was expressing itself in the lungs now, and that it was not a reinfection from outside, but from inside, which led to the lung trouble.

PROBABLE TUBERCULOUS NATURE OF "IDIOPATHIC PLEURISY WITH EFFUSION."

Similar experiences recur so frequently that I hink quite a number of us, particularly those whom we call experienced members of our proession, who have a much more thorough knowedge of the course of tuberculosis in the human animal than comparative beginners, like yourselves and myself, could give many stories showing how a uberculous subject may show invasion of this, hat, or another system at successive periods hrough a fairly long life. Are we really at the present day quite satisfied as to the genesis of the so-called idiopathic pleurisy with effusion, as it occurs in the young? It is so well known that many of these cases will ultimately develop consumption that insurance companies shy at them. There may be no sputum in such cases, or, if there s any, neither it nor the effusion shows tubercle bacilli. Only once have I ever had the opportunity of seeing the pleura in such a case. The patient concerned died three to four days after the removal of a pleural effusion; the pleura was found covered with millions of grey or white tubercles. Fortunately many of these cases of tuberculous pleurisy with effusion seem to put off pulmonary tuberculosis and consumption for many years; but only too often these diseases supervene eventually. I think we *must* feel that we all harbour the tubercle bacillus, and its activity may be revealed at various periods of life; once, or more than once, in the same tissue or organ, or in different ones; or the organism may lie dormant throughout the whole of life. It is quite true that I do not know what is the condition of the human body between these various manifestations of this latent tuberculosis. So I must simply call it a theory.

THEORY OF REINFECTION.

There is another theory which to my mind is not so near the truth as the one we have just been considering. There are those who consider that though so many children may be infected by the tubercle bacillus they master the infection completely, and are no longer tuberculous. If later on in life they show a tuberculous lesion, such as a tuberculous arthritis, this is due to a fresh infection from outside! The tuberculous arthritis recovers, the tuberculosis is again mastered. If spinal caries shows itself later on, or a tuberculous disease of the urinary system, or at a long last tuberculosis of the lungs, each is due to a fresh reinfection! My reason for asking you to consider these two hypotheses very closely is that I think it is so important that you should make up your minds on the point, because your attitude towards the treatment of tuberculosis and the management of your patients is so vitally influenced according to the view you hold. You may say that so far as you can see, neither hypothesis has been exalted into a fact, or even to a theory, and it is useless to act as if either was true, to the exclusion of the other. Before you finally take up this non-committal attitude you must realise that by doing so you are not going to be of much use to your patients. Moreover, your patients will soon find you out, and you will be left with two alternatives, to be non-committal and tell the whole story to each patient, and a few will remain content; the rest will suspect you, and rely upon the help of someone who holds one or other view whole-heartedly. I need hardly say that some will fall into the hands of practitioners who do not know which view they hold, or, following the policy of "hunting with the hounds and running with the hare," hold whichever view is convenient at the moment.

THEORY OF AUTO-INFECTION.

I will put before you one or two further points which influence me very much, and have confirmed me in the belief that probably in a large majority of the cases reinfection takes place from within. I think it has been your experience, as it has been mine, to be present at an operation on the abdomen, which has been undertaken for quite a different purpose, and that purpose has been carried out, but at the same time well-marked lesions of a tuberculous character, sometimes active and sometimes inactive, have been found as well. The wound has been closed and the patients appear to have recovered absolutely. Such a fact as this, coupled with the fact that we so often find inactive and active tuberculous lesions in the bodies of patients, who die of some other complaint, has converted me to the view that a single, or repeated tuberculous manifestation is but the expression of a reinfection of this, that, or the other tissue from a deposit, dormant hitherto, of tuberculosis laid down in childhood. I do not deny that in some cases reinfection may take place from outside, either as a result of a small or large dose of fresh tubercle bacilli entering the system when the resistance for the time being is low; but I think this is exceptional.

The other hypothesis has been run recently for all that it is worth, and because we are not finding an improvement in the figures, say, of cases of development of pulmonary tuberculosis, the hypothesis has become suspect, and there is a change of the pendulum to the more stable position taught by pathology. Do not mistake me: I do not wish to see a return to expectoration in our railway-carriages or buses, or on the pavements of our streets. I do not want to abolish the sputum flask or the sputum pot. Indeed, I do not want to abolish anything which is good-mannered, as opposed to bad-mannered; but what I do hope to see is a marked reaction against the hypothesis of reinfection from outside, so that the liberty and comfort of the patient afflicted are not curtailed.

The critical layman, listening to this difficulty of ours, and knowing that our profession is divided, one part believing that in the majority of cases reinfection takes place from within, and the other believing the opposite, and neither group of physicians being able to produce evidence which could convert either hypothesis into a fact, would probably come to the conclusion that we modern physicians are not far removed from our predecessors who combined some medical knowledge with a large amount of reliance upon mere creeds. I think such criticism would be unfair, for after all we admit the shortcomings of our present knowledge, and admit, too, that what we have been doing in recent years is to try to see what will happen with our tuberculous patients if our treatment, prophylactic or curative, of the tuberculous person was based on the hypothesis of reinfection from without. Some of us suspected failure from the outset; an increased number of us view it with suspicion now because evidence is not forthcoming that tuberculosis is being lessened in incidence or in severity as a result of the establishment of tuberculosis dispensaries, of notification, and of the segregation in sanatoriums and other institutions of the tuberculous subject. This is exactly what we should expect if we confessed that the cure of tuberculosis has not been found, that the tubercle bacilli gain access to civilised humanity universally in childhood, and that in a great majority of cases if tuberculosis of any organ develops in later life, this is but reinfection from within the body from foci of the disease already established.

Doubtful Value of Sanatorium Treatment.

Let us turn now to another fact which I owe to a colleague. He has lived through the period before sanatoriums were introduced, and he has lived through the period when sanatoriums and sanatorium methods have been in vogue. He tells me that to go round the Bromptom Hospital wards now and compare the condition of our patients there with that of the patients admitted to the wards before the days of the introduction of open-air methods would convince anybody that the newer methods of open-air management were curing our cases of pulmonary tuberculosis. To his mind this is a fact, and he is supported by the increased efforts being made to establish more sanatoriums in this country, and by the fact that the nation has spent something like £5,000,000 since 1912 in effecting the cure of tuberculosis on these lines. He is also supported by the well-attested observation that the modern type of tuberculous patient lives infinitely longer than a consumptive of former days. He pointed out how rare it is to find amongst our patients those who were drenched in perspiration, who were expectorating large amounts of sputum, running high temperatures, and gradually developing lardaceous disease. I could support this statement, and say that in seven years' work in the wards here it was rare to see a case of advanced consumption, that relatively few patients die in the hospital—many less than used to do—and I have never seen a case who has died reveal lardaceous change in the post-mortem room. I should be very glad to acknowledge that I was convinced by my colleague that this wonderful change was all due to open-air methods. But there is an obvious fallacy, because in former days this hospital was founded and used for the admission of consumptive patients—in other words, for the very patients who are now almost excluded. We should expect that those patients would be very ill when admitted to the hospital, that many of them would die in the hospital; for it is well known that the life of a consumptive was, and still is, a comparatively short affair. If you visit the wards of the hospital to-day you would be struck by the healthiness of the patients, by the number of them who have no fever and are allowed to be up and about every day—even all day. Some of them have pulmonary tuberculosis, and are being "shepherded" into the Frimley Sanatorium, if they are able to do physical work, or into the sanatoriums provided by the State if not able to work. Others of them are merely taken in for observation, and I think I may say that the reason for the admission of some of these latter cases is sometimes that the patient has symptoms which, on careful general examination, can be referred to disorder of some other system than the lungs, but which have in error been referred to those organs, and to tuberculosis of those organs. Some patients are admitted for being under weight, for debility, for anæmia, because these symptoms are associated with a history of cough or of tuberculosis in some other member of the family. Can it be wondered at, then, that the material in the wards of this hospital at the present day shows so much less invalidishness than before sanatorium methods were introduced? Can it be wondered at that deaths are fewer here, and that the patients admitted here live longer than they used to do? Only a few cases of advanced consumption are ever admitted to the wards of this hospital now, and pressure is brought to bear to have them discharged as soon as possible. The Insurance Act then deals with these patients, and labels them "fit for domiciliary treatment," and they are sent to our infirmaries or homes for the dying, or, where the relatives can afford or prefer it, they are allowed to return to their own homes.

So I hope you see that the fact which my colleague insisted upon is far from being *proved* to be a fact. It appears to be a fact not because open-air treatment is curing our patients when other methods fail, but because an infinitely healthier group of patients is being subjected to open-air methods than ever was submitted to the treatment, whatever it was, which was in vogue in this hospital formerly.

Unreliability of Statistics.

The returns of the Registrar-General for a good many years prior to, and in part inclusive of, the period when sanatorium treatment was introduced into this country show a great improvement in the number of deaths from tuberculosis. That is a fact which is incontrovertible; but there are many divergent views of its explanation. The favourable reduction was world-wide. Some have explained it by improvement of the general hygienic conditions of life, better housing, better food, &c. It has, however, been pointed out that if this curve of improvement in the deaths from tuberculosis was but a part of a general fall in deaths from tuberculosis, that about the time of the Tudors the deaths of all humanity would be mainly from tuberculosis, and if the general average age of death was the same then as now, scarcely any one in the Tudor period would have lived beyond 50 years, or, if they did, would be in well-advanced consumption. It is more probable, as Professor Karl Pearson points out, that the deaths from tuberculosis followed curves of increasing and decreasing severity, much as we see in the curves of mortality from other infective diseases, the great difference being that in the case of tuberculosis, a very chronic malady, but few physicians can say they have seen the beginning and the end of a single wave in the mortality curves.

We must not claim that open-air methods have been proved to cure pulmonary tuberculosis or consumption. Our statistical methods are at fault. They will not convince any ordinary critical person. I will give you an example of what I mean, drawing my material from the published records of an institution which devotes itself to the cure of pulmonary tuberculosis. It points out that 11 cases entering the institution in 1905 had one lobe of the lungs affected with tuberculosis, as proved by the presence of tubercle bacilli in the sputum. The statistical report went on to show what happened to these cases in subsequent years. At the end of the following year eight cases were well and able to work. All that could be found out about the remaining three cases was that, at any rate, they were alive. Details are then given of the result of nquiry into the condition of these same 11 cases at he end of 1912. Not a single case was reported well and able to work," but as eight of the total umber could not be heard of at all, no deductions ould be made from this fact. Of the remaining hree, one was reported merely as "alive," two ere dead.

I submit to you that it would be very hard to xpect from that report any facts which supported he view that that institution was curing tuber-ulosis of the lungs. Curiously there was another et of 11 cases admitted into the same institution n the same year, 1905. In these cases three lobes f the lung were involved instead of one, and ubercle bacilli were present in the sputum. At he end of 1906 eight of them reported "well and ble to work," two of them reported merely 'alive"; one had died. In 1912 only one was 'well and able to work"; two were merely 'alive"; seven were dead; one was lost sight of. The perusal of these tables seems to point to the eduction that the earlier cases of frank tuber-ulosis of the lung are admitted into sanatoriums, ess of such number will be dead seven years afterwards than would be found dead amongst those who were admitted with more extensive disease.

When we ask ourselves how much support do reports like these give to the belief that sanatorium methods or sanatoriums cure tuberculosis of the lungs, the answer can only be, they give no support at all, and for the simple reason that we do not know what would happen, favourably or unfavourably, with cases not subjected to such treatment.

CONTRAST BETWEEN PULMONARY TUBERCULOSIS AND CONSUMPTION.

Listening to my remarks, some of you may be seriously alarmed about cases of tuberculosis placed under your care. You may be tempted to feel that I am painting a gloomy picture of them for the future; that they are bound to die, and that nothing will save them. I would beg of you to abandon such a view, and would point to the number of cases who, dying of some other disease, show that they have mastered tuberculosis of the lungs. This process of curing is probably going on in some individuals in this very lecture room. Many useful and long lives have been spent with tuberculosis held in leash, death occurring from some quite different cause. I am quite convinced that pulmonary tuberculosis is curable, just as any other form of tuberculosis is curable. I am not so sure about consumption, however, because the very nomenclature of the condition indicates signs and symptoms upon which few of us would like to express a cheery opinion. To my mind, there is an immense difference between pulmonary tuberculosis and consumption: they are not synonymous terms, and I am always glad to see that our notice board still retains the word "Hospital for Consumption" rather than making use of the term "pulmonary tuberculosis." I am quite convinced, and several of my friends here are also convinced, that the evidence is still wanting that sanatorium methods cure tuberculosis of the lungs or that they favourably influence the mixed infections which, added to the tuberculous infection, are responsible for what we call consumption.

Seeing how many cases of tuberculosis of the lungs, and even of consumption, live and work without ever going into a sanatorium, one is driven to the conclusion that it is the individual himself, or herself, who by reason of a resistance, which we do not yet understand, which we cannot measure, which we cannot increase or diminish, by any known system of medical treatment, who cures his, or her, tuberculosis.

DANGERS OF PROPHECY AS TO LENGTH OF LIFE.

I have another fact to bring before your notice—namely, that it is unsafe to prophesy how long cases of pulmonary tuberculosis, or of consumption, will live. On the one hand, we know that tuberculosis of the lungs in childhood, revealing evident signs of consolidation of the lungs, wasting, fever, loss of appetite, &c., will after a long last, pull through and apparently recover. On the other hand, how quickly some children seem to be carried off by the development of tuberculosis, following such an illness as whooping-cough or measles. The same warning is necessary in the case of adults. In every case of tuberculosis of the lungs, to "wait and see" must be our only programme. In general terms I think one may say the longer a case survives after any initial illness, or any initial symptom which is recognised to be of a tuberculous origin, the slower will be the further progress of the case, barring such accidents as hæmoptysis, pneumothorax, meningitis, &c. Whenever the tuberculous illness has only just declared itself and is revealed by a minimum of signs in the lungs, prognosis should not be attempted.

NEED FOR FURTHER EXPERIMENTAL EVIDENCE ON THE FACTORS INFLUENCING RESISTANCE.

A fact which is very important, and thoroughly well established, is that the instruction to notify cases of tuberculosis is disregarded wholesale. The patient's comfort, his right to liberty of action, his right to earn his living, and his right to "live with his own," to use an expression coined by a responsible Member of the Government quite recently, are felt by our profession to be paramount, and the behests of the Insurance Act are ignored, and they should be ignored, I think, until the Government is prepared, on finding that a certain individual is notified as a case of pulmonary tuberculosis, to keep him and those dependent upon his good health, as long as he has ill-health, and if he never can be restored to working capacity, until he dies.

Some of you have come from outlying States of the Empire, and you are carrying back impressions you have picked up in this country, especially with regard to the management we mete out to our cases of pulmonary tuberculosis. One of you has informed me that in his practice in a certain well-known State, in which he sees about 4000 patients a year, he has, on an average, only one suffering from tuberculosis of the lungs. I am familiar with the country of which he speaks; I know of its warmth and dryness, and judging from what I have seen of the homes of the rich and poor in London, and of the sort of life they have to lead from November to March of each year, I am quite convinced that the time has come for the *trial* of some other method for dealing with tuberculosis of the lungs. As you can guess from the remarks that I have uttered in this lecture, I am almost more alarmed by the mixed infection of the lungs than by the tuberculosis of the lungs which precedes it, because I feel that lung destruction—that is, consumption—is due to the mixed infection. We are already hearing favourable results of village settlements for those suffering from tuberculosis of the lungs in this country. I wish very much that it were possible to transplant the experiment to the dry, warm country above referred to, to see whether the absence of catarrhal infection of the lungs would not yield infinitely better results than the same methods carried out in this country. You observe I want a proper trial, with controls. We ought not to assume that *prima facie* such a plan would cure tuberculosis of the lungs or consumption; that was the way sanatorium treatment in this country was introduced. One experience of that kind should be quite enough. It is a certain fact to me that the scheme of curing tuberculosis of the lungs by sanatoriums in this country still remains to be proved capable of fulfilling its task. The large number of so-called suitable cases known to me who have gone through sanatorium treatment, and have not been cured, and have even got worse while undergoing the cure, considered with similar cases in which sanatorium methods seem to have effected a cure, make me wonder whether the cures, and the failures to cure when they have happened, were not, after all, dependent upon the success or failure of some factor other than the sanatorium treatment. I believe that other factor is most conveniently to be spoken of as the individual's resistance. All the members of a civilised community have been infected with the tubercle bacillus in childhood. Then why do they not all succumb to the infection? The answer must be, because they have resistance, which for all we know may be a constant quantity, may be of a low order, or high order, or it may be of varying quantity, changing from a high to a low order, and vice versa: it may become completely exhausted in a few years, or it may maintain its high value throughout life. I fully admit that whether a patient succumbs or not may be due to an increased or decreased virulence of the infecting tubercle bacilli, and may even be due to the fact that the infection is massive or only small in amount. It is not possible to influence the virulence of the infecting bacilli. It is reasonable to try to reduce the amount of infection each one suffers; but only so long as we do not impose hardships upon the individual affected. Can we influence the resistance of the body to -tuberculosis? We have done this already with regard to typhoid fever, and catarrhal infections of the respiratory tract by the use of vaccines. It is reasonable to think (1) that by the use of tuberculin very early in life increased resistance to subsequent tuberculous infection could be given to the child; (2) if an individual has already shown evidence of tuberculosis of the lungs, then vaccination against catarrhal infection should prevent what we call consumption. It seems to me that these are the two great possibilities for the future; but they should be *proved first*, just as I have hinted above we must experiment first before we say that removal to a warm, dry climate is also capable of reducing consumption. Do we know of anything which lowers the resistance of the individual to infection by the tubercle bacillus? We have strong evidence for believing that town life, indoor occupations, bad feeding, want of sunlight, &c., are all capable of leading to the development of tuberculosis. Such matters can be influenced, but we should be careful lest, for example, in securing plenty of fresh air, we do not pass from Scylla to Charybdis, for cold damp air in this country, at any rate, especially in the winter, has to be taken with large and sudden doses of hot, dry atmospheres, which leads to catarrh. Clinical study points clearly to the view that the lung destruction we call consumption may be due to the mixed infections which characterise bronchial catarrh. We can influence this agency, and I think it is of first importance that the experiment should be made. We must then leave to each individual the task of fighting the tubercle bacillus by his own resistance, because we have, so far, not shown experimentally that the resistance to the tubercle bacillus can be usefully increased by the use of tuberculin. I know a great question has been raised—namely, Is the resistance to tuberculosis diminished at all by the presence of the organisms of mixed infection? So far as I know, this has not been experimentally proved, and until that is done we can make no practical use of the theory one way or the other. I think it is proven that given the tubercle bacillus in the lung a certain amount of tissue is rendered less viable, owing to the direct effect of the tubercle bacillus. Such less viable, or even dead tissue, provides a suitable soil for saprophytic organisms, and possibly for pyogenic organisms. These latter organisms interfere with the ordinary power of the tubercle bacillus to produce fibrosis, and by the process of abscess formation lead to what we call consumption.

CARBON-MONOXIDE POISONING IN WARFARE.

By W. J. RUTHERFURD, *M.C.*, M.D., CH.B. GLASG.,
LATE TEMPORARY CAPTAIN, R.A.M.C.

IN addition to poisoning by the various "drift gases" and "shell-gas" fluids made use of by the enemy, there is another very important type of gas-poisoning met with in warfare.[1] This is poisoning by carbon monoxide, "mine-gas poisoning" as it is called, to distinguish it from the drift-gas poisonings; and it is usually met with among men of the engineer units engaged in the mining and countermining that of necessity accompany stationary warfare, and have done so at least since the days of Herodotus and Josephus.

The carbon monoxide, which has been described by Brouardel as holding first place amongst the toxic gases,[2] and is the toxic agent in these cases, is produced during the explosion of the charges in the mines, and is evolved in such quantity that in the case of a mine exploded in the month of September, 1916, the gas, issuing from the ground broken by the explosion, and taking fire, burned with a flame visible at a distance of a mile, and had not entirely ceased to burn at a quarter past four in the morning, five and three-quarter hours after the mine had gone up. Where the mine is more deeply placed, or where a smaller charge has been used, so that the surface of the ground has not been broken, the gas is either forced into the underground system of mine galleries or gradually percolates into the galleries through cracks and porosities in the ground, and in these circumstances the miners become subject to this form of gas poisoning, the severity of which may range from mere headache and debility to coma and death. Both among the Germans and among our own men many casualties have occurred in this way.

In some cases the reflux of carbon monoxide after an explosion has come up the mine-shaft and caused gas poisoning in persons in the trench in the near vicinity to the mine entrance. There is a persistent rumour, too, that during the first winter of trench warfare (and certainly such cases occurred during every subsequent winter of the war) there were cases of carbon-monoxide poisoning, some ending fatally, apart from mining work, due to braziers of burning fuel having been taken into dug-outs during the night, the dug-outs having been sheltered against the bitterness of the winter cold by a heavy blanket hung across the entrance, and effectually preventing the escape of the products of combustion. Carbon monoxide, as is well known, has the effects of a cumulative poison, even in relatively small quantities, although it is not possible to go as far as Claude Bernard, and say that every breath drawn in an atmosphere containing this gas kills a certain number of blood corpuscles, until they are all dead and respiratory exchange is no longer possible. The vast majority of cases of carbon-monoxide poisoning among soldiers, however, is true mine-gas poisoning in the literal sense, and occurs underground, the victims being almost exclusively drawn from those working in tunnelling and other duties connected with underground warfare. The case here quoted is an example of gas poisoning, where the gas had welled up the shaft of the mine, although the patient was not actually in the open air at the time he was gassed.

---

[1] In Penhallow's "Military Surgery" (1916) the only forms of gas poisoning mentioned are shell gas and drift gas.

[2] Les Asphyxies par les Gaz, les Vapeurs et les Anesthésiques 1896, p. 5.

J. M., aged 22 years. Eight days ago was gassed with carbon monoxide while he was in the sloping gallery leading to the head of the shaft at the time a small mine was exploded. The gas welled up the shaft, reaching the place where he was waiting. He became dizzy and weak, and came out into the open air; he has continued to feel "fair beat" ever since, with slight looseness of the bowels from time to time.

The problems of gas poisoning in mining operations in the chalk are quite different from those encountered in the working in a clay stratum, owing to the presence of fissures in the former and its porosity to gas, which may be retained for comparatively long periods and afterwards forced out into the workings by changes in barometric pressure or by a rising water-level in the chalk.

As has just been stated, the carbon monoxide, which is the toxic agent in these cases, is engendered by the explosives in use in the mining operations, and is liberated in relatively large amounts.

Poisonous Gas-production after the Use of Various Explosives.

The various explosive substances (with certain exceptions, such as the acetylene compounds) contain within themselves a considerable amount of oxygen, which is, however, generally insufficient for the complete oxidation of all the constituent oxidisable elements. In consequence, not only may there be the formation of carbon monoxide, but hydrogen, marsh gas, and certain other oxidisable substances may be liberated as the result of the detonation of various explosives. The methane is said to result from interaction of the hydrogen with the oxides of carbon as the hot gases cool down and not to be formed at the time of the explosion. Nitroglycerine is an example of the explosives which are completely oxidised on detonation, and this substance exists to the extent of 75 per cent. in dynamite and 30 per cent. in cordite, besides being present in smaller proportions in many of the blasting gelatins. Its detonation may be expressed by the following equation—

$$4C_3H_5(NO_3)_3 = 12CO_2 + 10H_2O + 6N_2 + O_2,$$

although it is capable in the presence of a suitable absorbent, such as exists in dynamite, of burning slowly in air, from which it absorbs still further oxygen with the formation of the higher oxides of nitrogen. The gases evolved from the ordinary detonation of nitroglycerine are sufficiently copious to give from 1 kg. of the explosive 713 litres of gas at N.T.P. when the water vapour has been condensed out. These gases, however, contain no carbon monoxide, although the oxides of nitrogen resulting from the imperfect detonation of a charge of dynamite are extremely pernicious in their effects if they happen to be inhaled.

Carbon monoxide is produced as the result of the use of a large series of explosives, such as gunpowder (whether in the form of rifle-powder, "cocoa powder," or blasting powder), gun-cotton (either by itself, or as cordite, of which it forms 65 per cent.; smokeless powder, which is 98 per cent. gun-cotton with 1 per cent. of acetone and 1 per cent. of moisture, etc.; or the blasting gelatins), and ammonal, the latter of which is used extensively and in enormous quantities, charges being laid and exploded such as had never been heard of or even imagined in times of peace. The fulminate in the detonators also liberates CO, but owing to the relatively small amount of this substance that is necessary, this factor may be ignored. The equation representing the decomposition of the fulminate in the detonators is as follows:—

$$HgC_2N_2O_2 = Hg + 2CO + N_2,$$

66 per cent. by volume of the small amount of gas liberated consisting of carbon monoxide; not, however, at the instant of detonation, as the molecular mercury liberated occurs momentarily in gaseous form also. The greyish fume given off on explosion of mercuric fulminate consists of finely divided metallic globules condensing out from the rapidly cooling gas.

The equation representing the explosion of a charge of gunpowder may be given as under:—

$$21C + 7S + 16KNO_3 = 13CO_2 + 3CO + 8N_2 + 5K_2CO_3 + K_2SO_4 + 2K_2S_3,$$

12½ per cent. of the resultant gases liberated consisting of this lethal substance in question. As the composition of gunpowder is variable, the quantity of gases evolved and their relative proportions varies with the type of powder that has been used. For instance, the so-called cocoa powder contains 79 per cent. of nitrate of potash, 2 per cent. of sulphur, 18 per cent. of charcoal, and 1 per cent. of moisture; black rifle-powder contains 75 per cent. KNO_3, 10 per cent. sulphur, and 15 per cent. carbon; while blasting powder contains 67 per cent. of nitre, 19 per cent. of carbon, and 14 per cent. of sulphur. The volume of gases evolved during the explosion of these three explosive mixtures, when reduced to N.T.P., is as follows, in each case 1 kg. of the explosive being used: in the case of cocoa powder 200 litres, from the black rifle-powder 275 litres, and in the case of blasting powder 360 litres. From certain French powders from 263 to 278 litres per kg. are evolved on explosion.

The detonative decomposition of gun-cotton, which may be considered as typical of the various compound explosives of which it forms part, may be expressed by this equation:—

$$C_{12}H_{14}O_4(NO_3)_6 = 7CO_2 + 5CO + 4H_2 + 3H_2O + 3N_2.$$

It will be seen from the above that in this case the percentage composition of the gaseous products of decomposition will stand for CO at about 22¾ while the gases are hot and the water present is in the form of fully vapourised steam, and about 26⅓, or well over one-quarter of the whole, when the water vapour has condensed out. In this latter case no less than 859 litres of gas containing this high proportion of carbon monoxide are produced, measuring—at N.T.P., of course—from 1 kg. of the explosive. It is said that where, in certain special circumstances, a charge of gun-cotton burns instead of exploding, as much as 40 per cent. of carbon monoxide may be present in the fumes evolved.

Formation of "Pockets."

It is the carbon monoxide thus produced, and produced in these high proportions and enormous quantities,[3] which is absorbed into the chalk and forced into the fissures, either existing naturally or resulting from the explosion of the charges that have been laid, that is being constantly encountered by those engaged in the work of the various tunnelling companies, and which frequently results in the occurrence of cases of gas poisoning of this specialised nature. Owing to the gas being contained in cracks among the chalk it is found in what are described by the miners as "pockets," and owing to this fact in many instances the gas is liberated too suddenly for the men to notice any alteration in the behaviour of the test animals (mice or canaries) that they have with them before they are themselves beginning to be affected. Usually the amount of gas set free by the disturbance of one of these "pockets" is not too great to prevent a realisation of their symptoms, in which case they usually seek the fresh air at once.

An official document affirms that "the formation of large quantities of combustible gases—CO, H, and CH_4—is generally indicative of poor detonation." Their presence depends, however, on the essential nature of the explosive used, though in a certain sense the occurrence of these gases in the galleries may depend on imperfect detonation. Where a well-detonated charge has been expected to break the surface a vent will, of course, be formed, permitting escape into the atmosphere of the gaseous products of the explosion. Where, on the other hand, the charge has failed to detonate properly (whether from an insufficient number or distribution of the detonators in a large charge, from deterioration of the explosive from damp or other cause, from imperfect tamping or the operation of other factors), the surface may not be broken, and the gases formed are forced under pressure into the surrounding broken-up ground from which they make their way sooner or later into neighbouring galleries, the leakage of gas into the workings sometimes continuing over a period of many days and being aided, as has been noted already, by factors such as a falling barometer and a rise in the level of the subsoil water. In an impervious stratum such as clay, which occurs largely along the northern sector of the Flanders front, the difficulties met with owing to the late presence of gas in the workings after a blow (as the explosion of a small mine or camouflet is often termed) are very slight compared with those occurring where the galleries run through chalk or other substances of a porous or permeable nature.

In the two examples here described the gas must have existed in some such "pocket," but was liberated in such large quantity that the men working at the face were rendered comatose with great suddenness, and when an officer, Captain P. T. Hough, M.C., R.E., had his attention directed to the occurrence he heard, he tells me, the stertorous breathing of the unconscious men as he was coming along the gallery, and before he had actually come in sight of either of them.

Captain Hough's report.—X was originally an incline 90 ft. long dipping 1 in 3, at the end of which was a 60° shaft going to a total depth of 45 ft. From this inclines were drawn in the form of a V. On April 26th, 1916, the enemy blew a large charge about 120 ft. from the shaft. On June 1st the left branch was blown with a charge of 20,000 lb. of explosive,[4] being then 110 ft. from the shaft and about 75 ft. from the surface. The shaft, although tamped, was so badly damaged as to make too long a process recovering it. Two inclines, 1 in 1, was accordingly started from the old shaft-head. Men frequently complained of gas, and two or three mice and canaries were lost. Work was continued in the left branch; several men were gassed, one or two having to go to hospital, during the days following. Most of these men complained of feeling very sick and even vomiting before a headache developed. In most case a sleep in the fresh air and rest put the men all right.

On June 30th I went down to listen in the left branch. The facemen complained of having felt sick from effects of the gas. I listened in this branch for about ten minutes, and then went into the right branch, travelling about 90 feet. Five minutes later I was called for from the junction, and on going into the left face I found the two facemen unconscious, with every limb twitching violently and the breathing stertorous. I heard the breathing even before seeing the men. With some difficulty we got them to the junction whilst the stretcher was being brought down. One of the two men was sick whilst being taken out into the trench and still unconscious.

Those of us who had taken the men out of the mine were very exhausted and strongly inclined to vomit on reaching the fresh air. On reaching the trench oxygen was administered until breathing became normal. The men were then carried down to the dressing station, where the other man was sick, though still unconscious. It was noticeable that their faces were quite a deep pink in colour.

The men were then taken to a well-ventilated dug-out and put in charge of stretcher-bearers. One of them woke up during the night to urinate, but the other slept on until well into the following afternoon. They were then sent to hospital.

7/7/16.

The story given by the two men themselves, however, when seen three days after they had been gassed, is to the effect that while at the mine face together they began to feel dizzy and came out into the fresh air. After about half an hour, one of them still feeling dizzy, they returned to the working face, and after working there for about 20 minutes became unconscious and had to be carried out. This occurred, so far as I can gather, about 7 o'clock in the evening; the one says that he remained unconscious (or rather sleeping) till 1 o'clock the next afternoon, while the other maintains that he was unconscious for 20 hours. Three days after the gassing they both complained of a feeling of debility, with headache and slight pains across the front of the chest. Both were constipated; one had vomited as late as two days after having been gassed; in neither was there any elevation of temperature, one of the two having his temperature subnormal, the thermometer registering 97·2° F.

Thirteen days after the cases of gas poisoning recorded above there was a further series of cases occurring in the same situation. On July 13th the ventilating pump was stopped for a short time in order to enable listening to be carried out without nterruption by extraneous sounds. Within a short ime two officers and a private were gassed, none of the cases being serious. Both the officers complained of headache, palpitation, and temporary debility, but were soon all right, and were able to carry on with their duties. From the private a more detailed story was obtained. He says that he was gassed at his place "in the face" while engaged in listening. He felt pains in the head and ached all over, and so came out into the fresh air. On coming out he fell, and lay where he was for about five minutes; he then got up and walked for about 30 yards, when he felt so exhausted and had such palpitation that he had to sit down. The next time he got up he walked a little farther, perhaps 50 yards, before he had to sit down again and rest. Then he proceeded farther and got a drink of hot tea, which he vomited in about half an hour. The next morning he was aching all over and could not get up, so he spent the day in his billet. The following day he felt weak and had slight headache, with slight looseness of the bowels; his temperature was 97°.

---

[3] For comparison it may be mentioned that the gases from a blast-furnace contain from 27 to 36 per cent. of carbon monoxide.

[4] The enemy is known to use charges of from 4000 to 15,000 kilogrammes; their explosives being donarite, westfalit, trinitroanisol, and glukauf, as has been proved by taking them over along with a district. We generally, but not invariably, used ammonal

Illustrative Cases.

The following are two striking examples of the way in which the gas collects in cracks in the chalk, from which later on it works its way out and causes symptoms among those working in the vicinity. The case in which the man was struck down at once by the gas issuing from a crack that he had uncovered is particularly interesting, as in these foudroyant cases of gas poisoning the test animals taken down into the galleries naturally fail to give preliminary warning of the presence of the gas, and for this reason their value as indicative of its presence has sometimes been discounted.

M. L., aged 43 years, was gassed two days ago while taking out the tamping from a mine that had been blown four days previously. While removing the tamping he came on a crack in the floor of the gallery, "and the gas just spewed out," rendering him immediately unconscious—foudroyé, to use Brouardel's description. He remembers nothing of what happened, being carried out comatose, and coming to during a two hours' rest in a dug-out. He was sent to hospital, returning from there yesterday[5]; is weak; sweats profusely and has no appetite.

J. K., aged 22 years, was engaged yesterday in driving a gallery through the chalk near an area that had been disturbed by the blowing of a camouflet a week before. There were two or three long cracks in the chalk a quarter of an inch wide and running obliquely and vertically along the entire length of the face, the result of the explosion. After working for two hours he began to have a slight headache, and at the end of the shift felt very feeble and had weakness of his legs. On coming into the open air he felt worse and sat down in the trench for a quarter of an hour before proceeding farther. On getting to the dug-out he could not eat, but had a drink of tea. After lying down for six hours he felt no better and was sent back to billets. This morning feels weak on the legs, has slight headache, and complains of tightness in the chest. Is pale and appetite is poor; otherwise his condition seems very fair. Temperature 98·4° F. The officer who sent this man out of the trenches believes that he is malingering.

Carbon-monoxide Poisoning from the Use of Blasting Charges in Military Mining.

The following is a report on carbon-monoxide poisoning as caused by the use of blasting charges on the working face during the military operations carried out by tunnelling companies. While driving a tunnel footage may be obtained in one of two ways, either by straightforward pick and shovel work, or by breaking up the material at the face by means of blasting charges placed in borings and suitably tamped in. The latter method is specially useful where a gallery is being driven through a hard stratum, and where working in chalk it is found that this becomes progressively harder and more compact in the deeper levels.

As has been shown, a wide range of explosive substances, from old-fashioned gunpowder, on the one hand, to the modern high-explosive compounds on the other, generate carbon monoxide on detonation, owing to their containing insufficient endogenous oxygen to oxidise completely all their carbon atoms during the sudden regrouping of elements that occurs when the explosion takes place. The explosion results in the liberation of large volumes of hot gas (varying in quantity for each kilogramme of explosive used from 200 litres at normal temperature and pressure in the case of some varieties of gunpowder, to 859 litres in the case of gun-cotton), containing a proportion of carbon monoxide that varies between very wide limits, but which may in some cases be as much as 40 per cent.; in quantities, in fact, which are as high as, or even higher than, the amount present in the flaming gusts of gas evolved from the top of a blast furnace. Naturally the presence of this gas in mine galleries after an explosion can give rise to serious trouble, which, however, may be largely guarded against by following the precautions that are laid down, and by resource to various types of safety apparatus when work requires to be pushed on in a poisonous atmosphere.

Not only is this toxic gas produced by the explosion of a mine, whether one of our own or one fired by the enemy, but carbon monoxide is present in the fumes given off by many of the blasting charges at the working face of the mine gallery. An exception must be made in the case of dynamite where this has detonated properly, as theoretically this substance, owing to the high oxygen content of the nitroglycerine it contains, should completely oxidise all the carbon present into CO_2, and have enough oxygen left over either to be liberated as such or to form, by combination with the nitrogen present, a certain quantity of the higher oxides of nitrogen; these oxides of nitrogen, although highly toxic, are to a certain extent brought down by moisture, and are at once fixed and rendered innocuous in contact with any of the carbonates of the alkaline earths, such as are abundantly present where work is being carried out in the chalk. With blastine, gelignite, and cheddite, all of which are used in working on the face, it would appear that a certain amount of carbon monoxide is formed, which in a small gallery may, even in the presence of good ventilation, give rise in susceptible persons to minor symptoms of poisoning, sufficient, perhaps, to interfere with their working for a longer or shorter period. Although cheddite contains chlorate of potash in addition to its other constituents (nitrotoluene and a resinous body), its use at times gives rise to symptoms similar to those met with where other explosives have been employed, and which are unquestionably the result of the presence of carbon monoxide in the fumes. Two sticks of cheddite, weighing together only 100 g., detonated on the working face, have been known to evolve sufficient carbon monoxide to affect a man engaged afterwards in clearing away the broken-down chalk loosened by the explosion. There is no question, however, that some men are more easily affected by the toxic fumes than others, in the same way that some men, more than others, have a tendency to exaggerate their symptoms.

---

[5] These dates refer to notes taken at the time.

The Effect of Certain Blasting Charges in C.O. Poisoning.

The following examples are illustrations of the effect of such blasting charges in giving rise to "mine-gas poisoning" from carbon monoxide:—

CASE 1.—Sapper J. M., aged 33 years. Two days ago was gassed with CO on going into mine gallery two hours after a blasting charge of 1½ cartridges of cheddite had been fired in a borehole. He went up to the face and did a little work among the broken chalk, when he became groggy at the knees and his head began to spin. The gallery was properly ventilated at the time. He came out of the mine, but when he got to the bottom of the shaft he needed assistance. On getting into fresh air he collapsed and does not well remember what happened. In about an hour he was all right again except for a headache, but rested for the remainder of the shift. Now feels weak about the legs and has a very poor appetite; is drowsy and tired, and has slept more heavily at nights since being "gassed." Is constipated. Temp. 98° F.

This case is a somewhat remarkable one owing to the length of time that elapsed between the blasting of the charge and the man being gassed. The reason is probably that there was a quantity of the gas forced into and among the broken chalk, and that when he began to stir it up with his shovel enough carbon monoxide was disengaged to give rise to symptoms. He was probably stooping down over his work and would inhale the fumes directly into his lungs.

CASE 2.—Sapper I. B., aged 24 years. (This man is naturally pale and nervous, and has an irritating nervous tic which consists in constantly smacking his lips loudly when spoken to and after giving any reply.) Two days ago was working at the face in the mine ten minutes (or so he says) after two blasting charges of cheddite had been exploded to break up the material at the face. The smoke was "working out very steady" as he worked. After half an hour at this work the shift finished and he came out. During this time his head had been spinning, but he had not felt badly any other way. On getting into the fresh air he fainted suddenly. On coming to he walked slowly down to the aid-post in the trenches, but when half way there had to stop for five or six minutes owing to a fresh accession of faintness. Now complains of pains in head; tongue and hands are tremulous; temp. 99° F. The following day his temperature was 98·8°, and he was otherwise much about the same.

CASE 3.—Sapper G. L., aged 24 years. Has a septic mouth, with diffuse toxic pains and headaches. Regardless of true ætiology, he attributes his discomforts to "eating the smoke" (i.e., to use another of his phrases, "swallowing a mouthful of the smoke") of the cheddite charges used for blasting in the mines, and says—in this case probably correctly—that he always gets headaches when he has to work where a charge of cheddite has been exploded recently.

CASE 4.—Pte F. S. (attached infantryman), aged 22 years. On the previous day was down a mine when a blasting charge was fired at the working face about 50 yards away. About a quarter of an hour afterwards he resumed his work of pushing a trolley loaded with bags of broken chalk from this face to the bottom of the shaft; while employed at this he became short of breath and began to feel weak; and when, 10 minutes after he had restarted working, white smoke from a charge blown in another gallery reached him, he felt so weak that he came out of the mine of his own accord. While climbing the ladder in the shaft he felt as though he might collapse and fall off at any moment, and on reaching the open air he had to lie down for 10 minutes. At present he is very confused and mixes up his story, so that it is with the greatest difficulty that any sense is got out of him; to get this story took over half an hour; he says that he has taken no food since being gassed, not owing to any feeling of sickness, but to complete loss of appetite. Tongue dry and denuded; bowels regular; temp. 98·2° F.

Carbon-Monoxide Poisoning in Civil Mining.

In mining operations in civil life carbon-monoxide poisoning is not unknown as the result of the use of blasting charges on a working face, but in these cases the quantity of explosive is very much greater than in the charge dealt with here. For instance, in the mines of Johannesburg a charge will consist of from 40 to 60 lb. of blasting gelatine distributed in 14 or 15 drill holes on the face and all detonated within a few seconds of one another by time fuse. The quantity of carbon monoxide evolved by the explosion of such a quantity of blasting gelatine may be considerable; but the quantity of deleterious gas generated from even a stick and a half or two sticks of explosive at the working face in one of the galleries in military mining is, as is pointed out here, quite sufficient to give rise to trouble.

The following are notes on the fumes of some explosives used in blasting on the working face in military mining operations, compiled for me by Lieutenant W. A. Ellison, R.E.

Blastine.—This gives an exceptionally dense fume of a white colour, and is very difficult to clear, even with a strong current of air. It is impossible to breathe long in these fumes, which cause intense headache.

Dynamite.—The bluish-white fumes from this are very heavy and remain low. With this explosive I find it is possible to breathe fairly well long before the gallery is clear. In this respect it is unlike "blastine." The effect of these fumes is to cause vomiting, but very little headache.

Gelignite.—This explosive does not give a very dense fume, and it is possible to get into a face quite soon after an explosion without any ill-effects. It clears itself fairly quickly even without a current of air. The fumes are white in colour.

Cheddite.—As regards fumes this explosive is the best. Many times after firing I have at once gone to the face and remained there without the slightest inconvenience. The yellowish fumes seem to clear themselves much quicker if gelignite has been used with the cheddite, but the fumes are much denser than when either explosive is used singly.

Note.—These papers were originally written in 1916, but permission to publish was withheld by the War Office as active warfare was then in progress.

RICKETS IN GERMANY:

A STUDY OF THE EFFECTS OF WAR ON CHILDREN.

BY PROFESSOR DR. ENGEL,
DIRECTOR OF CHILD WELFARE AT DORTMUND, WESTPHALIA.

AS food conditions began to get difficult in Germany medical men directed their attention at once to the effects which might be produced among the civilian population. It was to the nation's growing youth that thought especially turned, in the natural apprehension that there it might soonest lead to harm, and in consideration of the fact that the coming generation was the most precious possession of the State and must be kept in health, whatever happens.

For a long time no special effects on children were to be recognised. The weight at birth of infants remained, in spite of the hypo-nutrition of their mothers, practically constant. Only in the very latest period of the war did weakly children of under-weight begin to appear in greater number. The average of weight of new-born children, as observed in the lying-in hospitals, was then reduced. The general health of infants was good, the mortality-rate low. The number of births had fallen sharply, a circumstance which always reacts favourably on infant mortality. In addition to this, chiefly in consequence of the shortage of cow's milk, and encouraged by a special grant from the State, breast-feeding became more prevalent. The mortality-rate of infants was permanently reduced.

The position of children between two and five years of age, however, became more and more unfavourable. In spite of the fact that their number also fell and therefore, other things being equal, their prospect of life became better, the mortality-rate did not fall, but from 1915 on practically reached the infantile mortality-rate, and even exceeded it, of the year 1918. In normal times the mortality of the two-to-fives was not half as great as that of infants.

Rickets as a Cause of Death.

When the statistics are examined, it is seen that the increased number of deaths are not referred to the group of diseases which claims so many victims among children—namely, the infectious complaints.

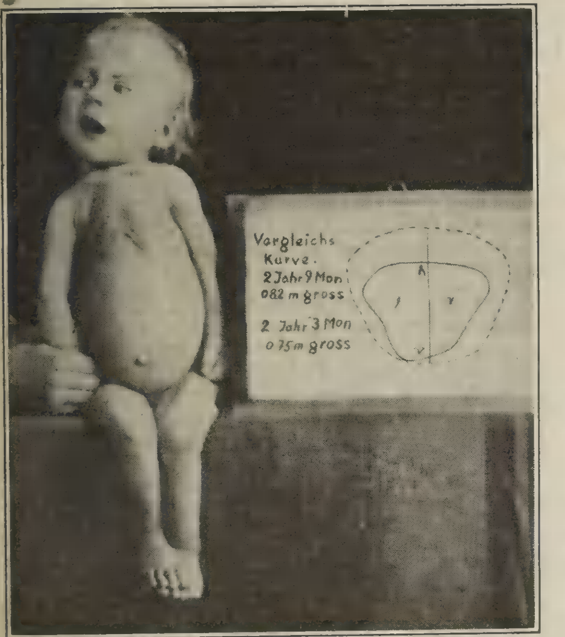

FIG. 1.—Photograph of a child, 2 years and 3 months old, with rachitic deformity of the chest. To the perimetric tracing is added for comparison that of a normal child of 2 years and 9 months.

There is to be noticed instead an increased number of entries of death attributed to inflammation of the lungs. Here, as is so often the case in death statistics, the term used does not quite meet the case, a fact which will immediately appear.

The experience at the clinic directs our attention to another chain of circumstances. From 1917 on the increasing occurrence of rickets became more evident. In some degree at the present time almost all children up to the most well-to-do are affected. As their social position becomes less favourable rickets becomes general, and assumes severer forms. These cases it is which are our chief concern. On the one hand, there are children who are in the highest degree backward in growth, and yet do not show coarse bony change apart from massive thickening of the epiphyses. These children are unusually small, but on the whole well proportioned. Their musculature is scanty and flabby. From the shapelessness of legs, and especially of the calves, it may be gathered that the children have never made any use of their lower limbs. The spinal column also frequently lacks the support of the musculature, so that the children fall together more or less and become highly kyphotic.

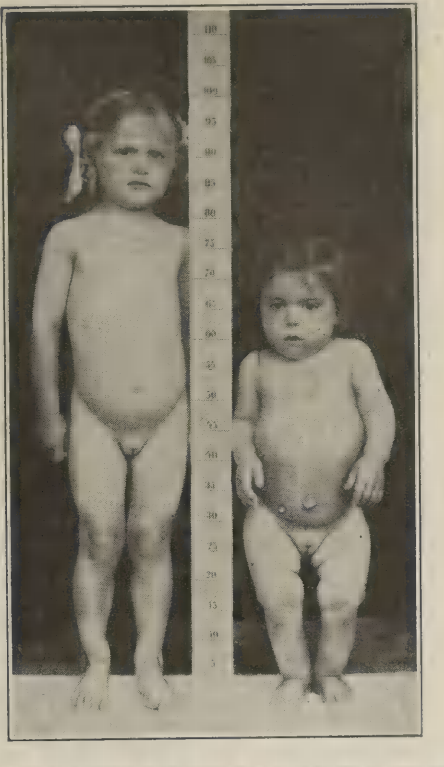

FIG. 2.—On the right, a rachitic dwarf, 4 years of age, after three months' treatment in hospital. On the left, a normal child of the same age. The height is given in centimetres.

In other cases, softening of the bones is more in evidence, in the limbs but more especially in the chest. All grades of deformity occur up to the most marked bending and bowing of the legs, of the spinal column, of the chest, and of the arms. But often the thorax is so badly affected that all other changes sink into the background. We have then children before us who are far too small for their age and in whom the thorax is seriously deformed. Under the influence of the negative pressure arising during inspiration in the thorax, the chest is crushed in from the sides and its cubic content much reduced. The lungs can no longer expand, with the result that the children are permanently dyspnœic. Even should no further complications arise, death may ensue with symptoms of acute air-hunger. Should complications be added to the existing respiratory insufficiency, be it only a slight bronchitis or a febrile illness, such as measles, death is the more likely to supervene. The picture of air-hunger is then so severe that as a rule the medical attendant assumes the presence of "inflammation of the lung" when it is only a question of pure respiratory insufficiency in consequence of a yielding thorax. At the autopsy we have often been able to satisfy ourselves of this fact. The ribs are weak and the chest falls widely open when the incision is made on the post-mortem table. In the pleural cavities are then seen the flabby, badly-ventilated, but not inflamed lungs. It is this increase of deaths of rachitic children in consequence of respiratory insufficiency that causes the increase of recorded deaths from "inflammation of the lung," and which makes it probable that the high mortality of little children is really to be ascribed to rickets.

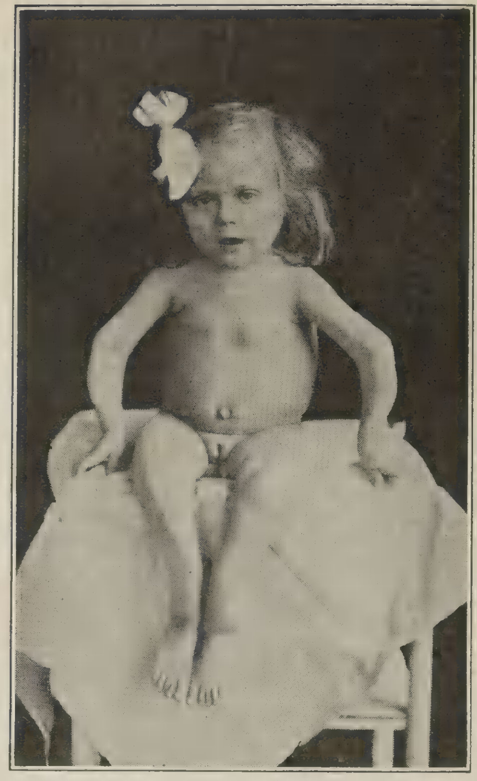

FIG. 3.—A girl, 6¾ years old, and unable to walk. This child took more than two months to learn the use of her legs.

Rickets as a Cause of Crippling.

Rickets as a cause of death is bad enough, but still more perturbing is the high number of cripples with which we have to reckon. First of all, the prodigious number of dwarfs. Observations, now going back a year or more, show that the growth tendency of rachitic dwarfs seems to be slight even after recovery from the condition which gave rise to the dwarfing. No final judgment can yet be passed; nevertheless it already seems probable that complete reparation will not occur. These dwarfs will in the majority of cases remain of lessened citizen value. Similarly with the numerous children in whom severe deformity of the skeleton has occurred. Those also, who in addition are frequently dwarfed, will not become full-valued members of society. On the contrary, it is to be feared that a not inconsiderable proportion of the young people of to-day will later become a charge upon the State.

When an attempt is made to form an exact position of the extent of those affected the ability to walk affords a great criterion. In a town such as Dortmund, in which the inhabitants consist chiefly of manual workers, and which has a larg youthful population, the number of small childre amounts to some 10 per cent. of the population, o say 30,000. From the practice of the clinics an consultations, it is estimated that more tha 10 per cent. of these children cannot walk. Number of them are three, four, or five years old, some eve older. Fig. 3 shows a 7 year old child unabl to walk.

As to the cause of the prevalence of rickets n doubt can arise. The food-supply, insufficient i amount and faulty in composition, which was al there was to give to children during recent years the lack not only of fat and milk, but also of fres vegetables and milk, are without question to b blamed. Most crucial seems to have been the lac of fresh milk. To this conclusion above all point the fact that rickets is far more widespread tha before among the children of the well-to-do also Even in the worst times much could be had fo money, but not milk. However much we wer inclined earlier to shelter our rachitic patient from excessive ingestion of milk, yet we must now admit that too great a lack causes the disease Should doubt arise as to the effect of the relative starvation, it must vanish when we see how, unde the prolonged influence of these harmful conditions, bony disease occurs in increasing exten among the higher age-groups also.

Treatment has always shown itself of rea worth, when the children could be brought to clean and healthy manner of life with sufficien nourishment. Hospital treatment has, in consequence, shown good results, although existing institutions do not avail by far to accommodate the great number of those requiring it.

A CASE OF
SEVERE CEREBRAL TOXÆMIA,
FOLLOWING AN INTRAVENOUS INJECTION OF NOVARSENOBILLON.

BY R. J. G. PARNELL, M.R.C.S., L.R.C.P.,
SURGEON LIEUTENANT-COMMANDER, R.N.; SPECIALIST IN VENEREA DISEASES, ROYAL NAVAL HOSPITAL, HASLAR.

With a Note by

SHELDON F. DUDLEY, O.B.E., M.B., B.S. LOND.
SURGEON LIEUTENANT-COMMANDER, R.N.; MEDICAL OFFICER IN CHARGE OF LABORATORY, R.N. HOSPITAL, HASLAR.

AT a time when the treatment of syphilis by arsenical compounds is being conducted on an increasingly vast scale, the details of the following case should be of interest. The type of toxic reaction described is fortunately rare. It occurs almost always some few days after an intravenous injection and, as a rule, ends fatally.

The special points of interest are that the recognised methods of treatment were of no avail, and that immediate improvement, and eventually complete recovery, followed the two measures adopted, which were: (1) continuous inhalation of oxygen; (2) an intravenous injection of urotropine and caffeine.

The patient, a healthy young man, 19 years of age, was sent to Haslar on July 31st, 1919, on account of manifest signs of syphilis, discovered at an examination for draft. Examination in hospital showed a slight degree of general glandular enlargement, a macular syphilide on trunk and limbs, and erosions of anal mucosa. Wassermann positive; urine normal; nothing else abnormal detected. No previous history of fits. On August 2nd 0·45 g. of N.A.B. was given intravenously without reaction. Four days later 0·9 g. was administered, also intravenously. No reaction. On the night of August 8th (approximately 56 hours after the second injection) the patient vomited. Temperature, 103·8° F. Next morning he vomited again. At 7.30 A.M. on the 9th he was found in a fit, "foaming at the mouth." Details of this attack are not available, as he was not seen in it by a medical officer. He slept most of the day, the temperature rising from 99° in the morning to 103° in the evening.

Further events were as follows: August 10th, *9.10* A.M., severe epileptiform seizure (second), preceded by cyanosis and contortions of the face and contractions of the left arm. Patient bit his tongue in the fit. *9.20:* Typical post-epileptic state. Pulse 80. Temperature 99°. *10.10:* Macular (arsenical) rash on left forearm. *11.45:* Patient conscious, but dull and lethargic; answered questions after a long interval. Rash generalised and very irritable; patient scratching skin, especially of perineum. *12.50* P.M.: Another fit (third); duration of convulsions, two minutes. *1.20:* Semiconscious; incontinence of urine; face cyanosed; restless; signs of cerebral irritation. *1.23:* Another fit (fourth). Duration, 1 minute. *1.30:* Temp. 100·6°; left arm twitching; patient unconscious. *2:* Semiconscious. *3:* Apparently conscious; would not answer questions, open mouth, or swallow; pulse 76, volume full. *4.15:* Another fit (fifth), lasting one minute; incontinence of urine; temperature 100·6°. *6:* Temperature 102°, pulse 92. *9:* Signs of cerebral irritation. August 11th, *4* A.M.: Another fit (sixth); right side of body more convulsed than left. *4.30:* Generalised muscular twitchings. *5.10:* Restless and irritable. *9:* Incontinence of urine and fæces; pulse 84; temperature 102·4°; unconscious; less irritable. *9.35:* Violent fit (seventh); deep cyanosis; pulse very feeble, but soon improved. *10:* Unconscious; pulse 80.

Treatment Adopted.

The following recognised methods of treatment had been tried without any signs of improvement: Adrenalin in 15-minim doses, calomel gr. i. hourly, chloral and bromide (by the mouth and rectum), venesection, and lumbar puncture (18 c.cm. of fluid withdrawn). Shortly after the seventh fit, at the suggestion of Surgeon-Lieutenant-Commander Dudley, continuous oxygen was administered, and an intravenous injection of urotropine 1·5 g. and caffeine 0·2 g. in 15 c.cm. of sterile distilled water. The course of events thereafter was as follows:—

12.30 P.M.: Sudden extreme cyanosis while patient was lying placid and unconscious; pulse 60; cyanosis soon passed off, without any fit developing. (N.B.—Each fit was preceded by cyanosis and distortion of the face. In the seventh fit the patient became black, and this, in association with a temporarily imperceptible pulse, gave rise to the fear that a fatal issue was imminent.)

From this moment onward improvement was steady and rapid.

3 P.M.: Colour normal; signs of returning consciousness. *5:* Patient opened his eyes and stated that he was "all right." During the night he slept quietly. Incontinence of urine at *1* A.M. on August 12th. At *9* A.M. his condition was normal, and but for incontinence of fæces on the night of the 13th, and relative amnesia for 14 days, his recovery was uneventful.

Examinations of the Blood, Urine, and Cerebro-spinal fluid.

Blood (August 10th).—Red cells, 6,650,000 per c.mm.; white cells, 19,200 per c.mm.; hæmoglobin, 80 per cent.; colour index, 0·6. No alteration in shape, size, or staining of red cells; two myelocytes seen. Differential leucocyte count: 68·3 per cent. polymorphonuclear cells; 26·7 per cent. small mononuclear cells; 5 per cent. large mononuclear cells.

Arneth count: 1, 2, 3, 4, 5.
66 25 8 1 0
91 9
Normal (40). Normal (60).

Arneth count indicates a very marked toxæmia.

On August 12th, the leucocytes numbered 10,300 per c.mm. Differential count: 58·5 per cent. polymorphonuclear cells; 34·0 per cent. small mononuclear cells; 3·0 per cent. large mononuclear cells; 4·0 per cent. eosinophiles; 0·5 per cent. basophiles.

Arneth count: 1, 2, 3, 4, 5.
29 36 27 8 0
65 35

The whole count suggests that the toxæmia is less acute.

August 14th: Leucocytes, 6300 per c.mm.; no important changes in differential count.

Arneth count: 1, 2, 3, 4, 5.
26 39 29 6 0
65 35

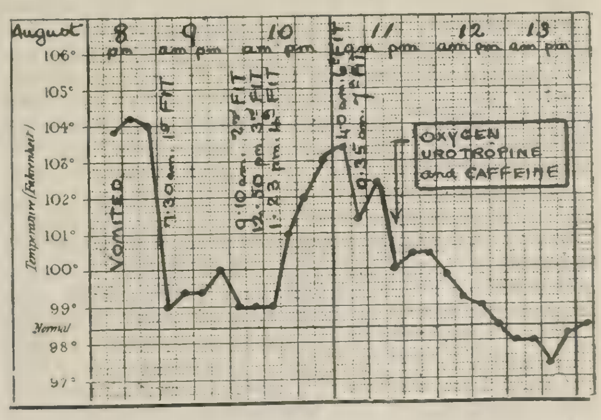
Urine (August 11th).—Acid, specific gravity 1015; trace of albumin; no sugar; urea 2 per cent.; large deposit of uric acid and amorphous urates. (It has already been noted that the urine, prior to treatment, contained no abnormality.)

Cerebro-spinal fluid.—18 c.cm. of clear colourless fluid. A mere trace of blood settled on standing. Normal amount of reducing substance and globulin. Cells: 5 lymphocytes and 110 erythrocytes per c.mm. Wassermann: Negative (using 0·8, 0·2, 0·05, and 0·012 c.cm. of fluid).

Remarks.

The amnesia at first was complete as far as the illness was concerned; the patient could remember nothing. He recalled being at his depôt, but he could not recollect being sent to hospital, nor any incident which occurred in hospital prior to the onset of the toxic symptoms. He had a vague idea that he had seen me somewhere before, but he could not recall the circumstances. He was greatly mystified as to why he was in hospital and how and when he arrived there. On August 26th (14 days later) he told me that he had suddenly remembered all the details of his case up to the day of the second injection of N.A.B.

The chart records graphically the features of the case in relation to the treatment. The improvement which followed the continuous administration of oxygen, and the injection of urotropine and caffeine directly into the blood-stream, is a striking fact. That it was due to one or other of these measures, or to both, seems a not unreasonable assumption. The prompt treatment of future cases of this type by these two measures may throw further light on the matter. The administration of oxygen was not stopped until 9 A.M. on August 12th, when the patient had been conscious for eight hours.



After History.

The patient returned from convalescent leave on Oct. 5th, 1919. He looked extremely well. His memory was normal.

Wassermann (Oct. 10th), weak positive.

Urine (Oct. 8th).—Cloud of albumin; the deposit contained a few crystals of calcium oxalate; no cells. Oct. 12th: Nil, abnormal.

Blood (Oct. 7th).—Leucocytes, 7200 per c.mm.; polymorphs, 36·8 per cent.; small mononuclears, 59·2 per cent.; large mononuclears, 3·2 per cent.; eosinophiles, 0·4 per cent.; basophiles, 0·4 per cent. (The excess of small mononuclear cells may have been associated with latent syphilis.)

Arneth count: 1, 2, 3, 4, 5.

$$\underbrace{19\quad 29}_{48}\quad \underbrace{31\quad 18\quad 3}_{52}$$

He was discharged to duty on Oct. 14th, 1919.

Note by Surgeon Lieutenant-Commander DUDLEY.

These cases of delayed 914 poisoning are probably accompanied by anoxæmia—i.e., insufficient supply of oxygen to the tissues. In the case just described the attacks of cyanosis are the chief evidence of this anoxæmia, which may well be of the type that Haldane[1] describes as due to the alteration of the dissociation curve of oxyhæmoglobin, whereby oxygen diffuses less easily into the plasma. The highly acid urine with a very heavy deposit of uric acid crystals suggests the possibility of a breakdown in the mechanism controlling the hydrogen-ion content of the blood, which in turn prevents the respiration centre from performing its function normally. The lack of dyspnœa, the loss of consciousness, and the amnesia resemble carbon monoxide poisoning, which is a definite anoxæmic condition. It was these observations, together with a favourable experience of the use of oxygen in influenzal broncho-pneumonia, also an anoxæmia, which suggested that oxygen might be of use in this case. The urotropine was given, as H. Michel[2] had reported successful results with it in acute mania and delirious influenzal broncho-pneumonias, supporting his clinical experience by animal experiments. Intravenous urotropine produces a profound diuresis, and H. Michel thinks toxins are eliminated this way via the kidneys. Should this man's recovery be in any way due to the therapeutic agents employed, it may reasonably be supposed that the oxygen held in check the anoxæmia, while the urotropine stimulated the kidneys to remove some poisonous product resulting from the arsenical injection. As far as the experience of one case goes, it would seem that of the two agents employed the oxygen was the more useful. The Arneth count in this case is interesting as showing how a chemical poison acts the same way as a microbial one on the nucleus of the neutrophile leucocyte. Another arsenic compound, AsH_3, acts exactly the same way.[3] A comparison of the Arneth counts on August 10th and 12th is strong evidence that a large quantity of deleterious substance must have been got rid of by the organism between those dates. While admitting the danger of drawing conclusions from a single case, considering the fatality and anxiety these severe toxic reactions cause, the use of oxygen in these reactions is worth a further trial.

THE SCHICK REACTION

FOR THE DETERMINATION OF SUSCEPTIBILITY TO DIPHTHERIA.

By H. MASON LEETE, M.B., B.S., B.HY. DURH.,
M.R.C.S. ENG., L.R.C.P. LOND., D.P.H.,
SENIOR MEDICAL ASSISTANT AND BACTERIOLOGIST, EDINBURGH CITY HOSPITAL.

THE object of this paper is to show the results of an investigation made on the subject of the Schick test[1] with a view primarily to the forming of some opinion as to its reliability, its difficulties, and its suitability for application in general and hospital practice, together with the advantages that might be expected to arise therefrom.

The test is performed by injecting a very small dose of diphtheria toxin into the skin, and noting after a certain lapse of time whether there is a reaction produced or not. If there is a reaction the test is said to be positive, and this result indicates that the subject lacks natural antitoxin immunity, and is therefore more likely to be susceptible to diphtheria. This reaction is due to the irritating effect of the toxin on the skin cells. When the patient has circulating in his blood natural diphtheria antitoxin the injected toxin is neutralised, so that no local reaction is produced. The test is then said to be negative, and the subject to be immune to diphtheria.

The toxin injected is a ripened one which has been recently carefully standardised and its minimal lethal dose (hereafter indicated as M.L.D.) accurately determined. The M.L.D. is the smallest amount of toxin that will produce death in a 250-gramme guinea-pig within four days. Such a toxin is taken, and suitable dilutions made until we have a diluted toxin containing one-tenth of an M.L.D. in 1 c.cm. The amount actually injected in the test is 0·2 c.cm. of this diluted toxin, which therefore contains one-fiftieth of an M.L.D.

Technique and Interpretation of the Schick Reaction.

This injection must be intracutaneous and of accurate dosage, and is best made by means of a fine needle fitted on to a hypodermic syringe graduated in tenths of a cubic centimetre. If the injection is made subcutaneously it is quite useless. A satisfactory injection should leave a round, white wheal the size of a large split pea, sharply defined, with the pores showing up well. The most convenient site for the injection is the flexor aspect of the forearm just below the fold of the elbow. The skin surface should be cleaned with a little alcohol or ether previous to the injection and the needle introduced very obliquely, the lumen superficial and when in position showing slightly through the upper layers of the skin. The operation is a painless one: 0·2 c.cm. having been injected the needle is withdrawn. The arm is then inspected after varying periods and a note of the readings made.

A typical positive reaction begins to show distinctly in from 24 to 48 hours and reaches its height about the third day. It is a sharply circumscribed area of redness with definite, though slight, infiltration, circular or somewhat oval in shape, and varying from half to one inch in diameter. This persists for about a week and on fading leaves a brownish, pigmented area which shows traces of desquamation. This pigmented area persists for a month or longer. A negative reaction is shown by the absence of redness and infiltration; after 24 to 48 hours there is nothing to be seen except perhaps a point of redness marking the needle track.

The reaction previously described was, as stated, a typical positive one. To distinguish such from a negative presents little difficulty, but in actual practice two sources of difficulty arise. The first is that in quite a number of cases the positive reaction though present is not very well marked and infiltration is absent. If, however, after the lapse of 48 hours, there has been a definite area of uniform redness, even though it be faint, which persists for several days and is followed later by pigmentation, the reaction is to be classed as positive. The crucial point seems to be that in a real negative test there is nothing to be seen at any period after the injection.

The second and more serious difficulty is the occurrence of "pseudo-reactions" which are non-specific and are believed to be due to the bacterial protoplasm or other protein substances in the toxin, and to be rather of the nature of local anaphylactic phenomena. A practised eye can soon pick out these pseudo-reactions in the majority of cases as they present quite a different picture from the true positive reaction. The redness of the pseudo-reaction appears earlier, reaching its height in from 24 to 36 hours; in shape it is large, oval, not definitely circumscribed, but fades away into the surrounding skin or has round it a secondary areola which is often well marked. There is frequently a large amount of induration associated with it. Its disappearance, like its onset, is rapid, and if it leaves any pigmentation at all it is an indefinite, faint, rather bluish area which does not show scaling. Pseudo-reactions are much more frequent in adults than in children. Though clinical differences are in the majority of cases quite sufficient to distinguish the true from the pseudo-reaction, and one would lay stress especially on the time element, when large numbers of these latter occur, as in dealing with groups of adults, it may be well to use "controls" of heated toxin. The toxin is heated to 75° C. for ten minutes and the heat destroys the specific toxin, but leaves unchanged the proteins to which the pseudo-reaction is due. The control injection is made on the other forearm. There may be no reactions—a clear negative. The two may be precisely alike and go through similar changes simultaneously—pseudo-reaction. The control may show no change and the other give greater or less evidence of a positive reaction. There may be reactions with both, but in the arm receiving active toxin there is a circumscribed area superadded to the pseudo-element which later shows pigmentation—a combined reaction—positive, though rare. As after a little experience it is quite easy in the majority of cases to distinguish a pseudo-reaction from a true positive clinically, the control test need only be used as an after-check in doubtful cases.

It is important to keep careful records and some definite scheme should be adopted and adhered to. Our records were kept in columns under the following headings:—

Name.	Age.	Date.	Ward.	Readings—			Remarks and result.
				24 hrs.	48 hrs.	10 days.	

It is probable that 72 hours for the second reading would be better than 48 hours, as it would allow more time for a pseudo-reaction to disappear and a true reaction to develop, thus aiding differentiation. Under "Readings" we indicate the amount and degree of redness and infiltration, whether that of a true or pseudo-reaction by an arbitrary system of signs such as: + + +, + +, +, −. The final result is only entered up at the end of ten days after consideration of all three readings. A most helpful point is what might be called the gradient of these readings. In a positive case the second reading shows an advance on the first and the third reading definite pigmentation, an "upward gradient" such as: +, + +, + +; while a pseudo-reaction tends to be downward as: + + +, +, −.

Results of Practical Experiments.

Having given a general idea of the Schick test, it is now proposed to give in more detail our practical experience with it. The tests were performed at the Edinburgh City Hospital, the majority upon patients newly admitted to the scarlet fever pavilions. In addition, tests were carried out in other wards for the purpose of detecting susceptibles and protecting them with prophylactic doses of antitoxin, the need having arisen. Some tests were performed on the medical and nursing staffs.

The first difficulty was to secure a satisfactory toxin. In a series of 200 cases the test was performed with a commercial toxin put up for the purpose of the Schick test by a large drug firm. From the first it was evident that either this toxin was weak or that the susceptibility of children here was very much less than that of American children as recorded by American workers on the subject. The reactions were comparatively few in number and in many cases not very well marked. The technique adopted was precisely that which has been described. We were fortunate in having our own impression of the weakness of the toxin confirmed by the opinion of Dr. Abraham Zingher, of the New York City Department of Health, whose experience of the Schick test is unrivalled, and who, by a happy coincidence, visited the hospital while these tests were in progress.

The results of this first series are shown in Table I. A column is added for comparison showing percentage results for a large series of cases (1200 in all) from the scarlet fever wards of the Willard Parker Hospital, New York, as given by Zingher.

TABLE I.—*Chiefly Scarlet Fever Patients. Weak Toxin.*

Age.	Total.	Negative.	Positive.	Per cent. positive.	Per cent. positive (Zingher).
6 months–1 year	3	2	1	33	50
1–2 years	12	7	5	42	68
2–4 ,, ...	40	27	13	32	66
4–6 ,, ...	23	19	4	17	53
6–8 ,, ...	27	22	5	18	37
8–15 ,, ...	59	52	7	12	28
15 and over ...	16	16	0	0	24·5
Total	180	145	35	19·5	45·3

From these results the conclusion was drawn that the toxin we were working with was under strength or otherwise unsatisfactory, a conclusion which was suggested by appearances in individual cases as well as by a consideration of the aggregate. Steps were therefore taken to secure a more satisfactory toxin, and I was fortunate in obtaining the help of Dr. R. A. O'Brien, director of the Wellcome Physiological Research Laboratories, who kindly supplied me with a toxin diluted ready for use in the test. From the first it was obvious that we had obtained an active and satisfactory toxin, the individual reactions being well marked and the percentage of positive results much increased. We found also that the toxin kept perfectly well though diluted to working strength for a period of at least five weeks, which was the longest period that we had any one batch in use. This is an important point, as American workers urge the making up of a fresh working dilution every time the test is used. We did not find this necessary, and our clinical readings were checked by laboratory reports, which stated that the toxin showed no deterioration after a much longer interval than the five weeks mentioned. Table II. shows the results of the tests with this toxin on scarlet fever patients.

TABLE II.—*Scarlet Fever Patients Only. Satisfactory Toxin.*

Age.	Total.	Negative.	Positive.	Per cent. positive.
1-2 years	8	0	8	100
2-4 ,, ...	41	9	32	78
4-6 ,, ...	90	27	53	59
6-8 ,, ...	93	39	54	58
8-15 ,, ...	190	84	106	56
15 and over	88	55	33	37·5
Total	500	214	286	57·2

It will be noticed that a large proportion are positive and that the positive reactions diminish with increasing age; they are more frequent among scarlet fever patients than among normal adults. In a series of 60 normal adults only 17 were positive, which gives a percentage of 28, as against 37·5 in the corresponding group of scarlet fever patients.

Abolition of the Reaction by Antitoxin.

One hundred and ten cases, all of whom had previously received therapeutic doses of antitoxin at periods varying from 1 to 70 days before the performance of the test, were tested, and all except one gave a negative result. The exception was a rather doubtful positive showing redness at 48 hours and faint pigmentation at 10 days. It occurred in a child of 6 years who had received 8000 units of antitoxin 26 days previous to the test. A remarkable feature was the large number of pseudo-reactions which appeared in these passively immunised patients. Sixty-one in this series were controlled with heated toxin, and of these 44 (72 per cent.) gave a definite pseudo-reaction. In a series of 104 controlled cases on the scarlet fever side only four showed pseudo-reactions. It would appear that the serum had sensitised the individuals and rendered them hypersensitive to the proteins of the toxin. A few cases among the scarlet fever patients which gave good positive results received 500 units of antitoxin, and were re-tested next day. Of 15 cases so treated all gave negative results, though three showed pseudo-reactions.

A number of cases which had previously been tested were re-tested at periods varying from one to three weeks to see if they gave the same results. Of 60 cases so treated 59 gave similar results, in many cases the actual readings corresponding to a remarkable degree. One case was recorded as negative which had previously been classed as positive. The error of method in moderately competent hands would thus seem to be from 1 to 2 per cent.

The Value and Future Use of the Test.

Some idea of the value of the test may be formed even in the comparatively short period that the patients remain in hospital. It is well known that in spite of all the usual precautions a few cases of mild diphtheria do occur from time to time in scarlet fever wards, and we proved no exception to this universal experience. Among our series of 500 tested cases 11 cases of mild diphtheria, confirmed by bacteriological examination, occurred. Of these 10 had given a good positive Schick, and the other one had been classed as doubtful, as he gave only a small point of pigmentation after ten days, and had not shown definite earlier reaction. Among a series of tests performed on members of the hospital staff, one subject who gave a negative result developed clinical diphtheria, but, as we have previously noted, there is a small margin of error, and it is possible that the case can be explained on that basis. In a ward where three cases of diphtheria cropped up at the same time we did not immunise two close contacts because both had given negative Schicks, and though of susceptible ages (2 and 3 years) neither developed diphtheria.

A certain number of cases were carriers before admission, or became so during their stay in hospital—that is, the diphtheria bacillus was found in their throats or noses on routine examination, but there were no clinical symptoms. Among 32 carriers, 18 were negative and 14 positive to the Schick test. This latter fact shows that immunity may depend on other factors than the presence of antitoxin.

We have had as yet no opportunity of proceeding to what is one logical outcome of the Schick test—the active immunisation of those giving a positive reaction by means of toxin-antitoxin mixtures—but it is hoped that shortly the difficulties will be overcome, and that we will be able to immunise those susceptible members of the hospital staff who come in contact with the disease. Park and Zingher[2] have shown that the great majority of susceptibles can be immunised in this way, though the process may be rather a slow one, and immunity, as shown by the disappearance of a positive Schick reaction and the presence of antitoxin in the blood, may not develop for several months. With such methods of detecting susceptibles and their immunisation it would seem that a new era is dawning in our attitude to diphtheria, the era of satisfactory prophylaxis; and it is this wide view of the Schick test that one would urge. It is more than of merely clinical value, and is therefore worthy of further investigation and trial, especially by those who are concerned with that most important aspect of medicine—prevention.

Conclusions.

1. The Schick test appears to be of definite value in detecting diphtheria susceptibles, and as such has many possible applications.
2. It is easy to perform and free from any danger.
3. A reliable toxin and careful technique are essential.
4. Once the differences between a positive and a pseudo-reaction are appreciated reading is easy, but if there is any doubt controls of heated toxin should be used.
5. The best times for readings are 24 hours, 3 days, and 10 days after the test.

I have to thank Dr. Claude B. Ker, at whose instigation the work was undertaken, for permission to perform the tests and to publish the results.

DEATH OF DR. G. F. ATCHLEY.—Dr. George Frederick Atchley died recently at his residence, Redland, Bristol, in his eighty-fifth year. He graduated M.B. of London University in 1861, and shortly afterwards commenced practice in Bristol. He was formerly surgeon to the Bristol Hospital for Sick Children, and at the time of his death was honorary consulting surgeon to the Bristol General Hospital. Dr. Atchley had at one time an extensive practice in Bristol and Clifton and was highly esteemed.

THE TREATMENT OF MALARIA IN MACEDONIA.

BY ARTHUR G. PHEAR, C.B., M.D. CANTAB., F.R.C.P. LOND.,
PHYSICIAN TO THE ROYAL FREE HOSPITAL; LATE CONSULTING PHYSICIAN TO THE BRITISH SALONIKA FORCE AND TO THE ARMY OF THE BLACK SEA.

IN view of the special interest taken in the treatment of malaria at the present time, it may be opportune to place on record an outline of the methods which, in the course of three seasons' experience, came to be regarded as the most effective in dealing with the disease in Macedonia. In malaria, as in every other disease, the details of treatment are necessarily determined by the special requirements of individual cases, and in the following remarks no more is attempted than to indicate the general lines along which treatment was directed in the various medical units of the command. The first essential in the treatment of every case was found to be the administration of an initial dose of calomel, followed, if necessary, by a saline aperient. This preliminary is of the greatest importance, as, if it is neglected, quinine administered by the mouth may remain to a large extent unabsorbed and inert. In cases of moderate severity quinine sulphate in solution was then given by the mouth in daily quantities of 45 gr. divided into three equal doses for at least three days, and for longer if the pyrexia persisted. The sulphate was chosen for routine use, partly on economical grounds and partly for the reason that the stock of bihydrochloride was for a time limited, and had to be reserved for the special purposes of intramuscular and intravenous injections, and for the small group of cases in which the highly acid solution of sulphate led to digestive disturbances. After the temperature had fallen to normal quinine was continued in the reduced daily dose of 30 gr. until the end of the second or third week from the beginning of [the attack. "Week-end" quinine—that is, 30 gr. daily on two successive days in each week—was then begun and continued for an indefinite period. In the earlier stages of our experience a smaller daily dose of 30 gr. was thought to be sufficient for the initial treatment of cases of ordinary severity, but the great importance of obtaining an immediate maximum effect, especially in primary attacks, was soon recognised, and the smaller dosage was seldom used except in the treatment of relapses of comparatively mild character.

In the treatment of more severe or more persistent cases a daily amount of 60 gr. was given. The whole of this may be administered in four 15 gr. doses by the mouth, or a part may be given intramuscularly. In cases of persistent vomiting or marked digestive disturbance oral quinine is either rejected or remains largely unabsorbed, and the advantages of the intramuscular method are very great. It was found convenient in these cases to give two intramuscular injections, each of 20 gr., one in the morning, the other in the evening, supplemented by 20 gr. of the bihydrochloride by mouth in the course of the day. As soon as the severer symptoms were under control oral administration of quinine was resumed.

It may here be pointed out that in any given case of malaria the amount of quinine and method of administration have to be determined more by the clinical features of the case than by the type of parasite found in the blood. The severest clinical manifestations were sometimes present when the benign tertian parasite only was demonstrable in the peripheral blood, and, on the other hand, a subtertian infection was not infrequently associated clinically with comparatively mild symptoms.

Cerebral Malaria.

On the earliest appearance of cerebral symptoms it was the practice to give quinine intravenously, and there is no doubt that by the prompt employment of this method of treatment many lives were saved. The treatment carries with it certain risks, and it is preferable to give a small or moderate dose in the first place and to repeat it if necessary rather than to give a single large dose. Various degrees of dilution were tried, and the most favourable results were obtained with a solution of 10 gr. of the bihydrochloride in 20 c.cm. of normal saline. Of this solution 15 to 20 c.cm. were injected slowly into the vein. By the use of a fine needle the double purpose was served of facilitating the entry of the needle into the vein and of ensuring slowness of administration. Except in special cases it did not appear that there is any gain in using a higher dilution than that stated above; on the contrary, unfavourable symptoms, such as convulsions and hyperpyrexia, were sometimes observed to follow the introduction of a large volume of fluid in cerebral cases. The intravenous injection should be supplemented by an intramuscular injection, which by its slow absorption ensures a continued quinine effect. Further treatment was determined by the course of the case; in some it was sufficient to continue intramuscular quinine; in others, repeated intravenous injections were necessary. In a few exceptional cases large doses of quinine, up to 100 or 120 gr. in the 24 hours, given by the combined intravenous and intramuscular methods, were needed before the acute symptoms were brought under control: it was uncommon for any unfavourable consequences to follow the use of these somewhat heroic doses. Quinine amblyopia, undoubtedly the most serious complication of quinine administration, was observed in a few instances only, nearly all of which were cases of a severe malarial infection, rendering the use of large doses imperative. With rare exceptions the loss of vision was transient.

Convalescence.—During convalescence a tonic mixture containing iron and arsenic was given, and a varied diet on a liberal scale was found important at this stage in establishing health and preventing undesirable after-effects. In primary attacks it was found desirable that patients should remain in hospital for a total period of at least three weeks, and should not be discharged to convalescent depôt until the temperature had been normal for ten days. In slighter attacks of recurrent malaria a stay of four or five days after the temperature had subsided was usually sufficient. In the more pronounced degrees of anæmia the arsenical element was pushed; this was done either by increasing drop by drop the dose of liquor arsenicalis by the mouth up to the verge of tolerance; or by using an organic preparation, such as sodium cacodylate hypodermically; or, in exceptional cases, by the intravenous injection of galyl. In one or two extreme cases of anæmic cachexia blood was transfused with good results.

Intramuscular quinine.—There was almost a consensus of opinion among clinical observers in the

Salonika command that a given quantity of quinine is more effective and speedy in its action when introduced intramuscularly than when given by the mouth. In the light of this definitely formed opinion it is interesting to note the experience of Captain K. McLay and Captain T. S. Hele, of the Malaria Enquiry Laboratory, who found that parasites disappeared from the peripheral circulation, and that in the healthy subject quinine was excreted more speedily after oral than after intramuscular administration. There is, however, no doubt as to the great value of the intramuscular method in cases of vomiting and other conditions in which intestinal absorption is impaired; when it is desired to introduce a larger amount of quinine into the system than can conveniently be given by mouth; or in cases of cerebral malaria as a supplementary measure to intravenous injections. Considering the enormous number of intramuscular injections that were given, it is remarkable how few and trivial the local ill-results have been; the risk of these is negligible if obvious precautions are taken to avoid sepsis and injury to nerve trunks. A certain limited degree of tissue-necrosis is probably an almost constant result, but it is exceptional for this to occasion any symptoms or signs beyond transient discomfort and a localised induration which speedily disappears and leaves no permanent disability. It was found, however, that a more serious degree of necrosis, amounting to extensive destruction of muscle tissue, may occur if repeated intramuscular injections are given to patients with seriously lowered vitality, such as those suffering from the effects of chronic dysentery; in such cases all the circumstances should receive careful consideration before the use of intramuscular quinine is decided on.

Rectal and subcutaneous quinine.—As an exceptional measure quinine was administered per rectum in doses of 5 to 10 gr., dissolved in 5 to 10 ounces of saline. This method proved of value when it was desired temporarily to supplement the amount of quinine introduced by other channels. The subcutaneous method was also employed in a small series of cases by Major E. B. Gunson, R.A.M.C., but did not appear to possess any advantage over the intramuscular method. On the other hand, the technique is less convenient and the risk of local complications is greater.

Galyl.—There was a marked divergence of opinion among clinical observers as to the value of arsenical preparations such as galyl in the treatment of malaria. At one time there seemed grounds for hope that with the introduction of galyl a preparation of remarkable value and activity had become available, but further experience was disappointing, and in the opinion of most observers the reputation of galyl as an effective agent in the control of the acuter phases of malaria was not established. But the preparation undoubtedly possesses some parasite-destroying properties, especially in subtertian malaria, and it may prove to be of value in the treatment of cerebral cases in which quinine has been pushed to the verge of tolerance and still symptoms of a heavy parasite infection remain. Apart from the question of its specific value, galyl has a definite use in stimulating the activity of the blood-forming organs, and was used with benefit in the severer grades of anæmia with cachexia and marked splenic enlargement following malaria and in convalescence from blackwater fever.

The Prevention of Relapses.

A very short experience in Macedonia was sufficient to bring home to all those concerned with the management of malarial cases the limitations of quinine treatment. Side by side with its remarkable power in controlling the acuter manifestations of the disease and its special importance in such conditions as cerebral malaria, when the life of the patient may depend on its proper use, there was accumulating evidence of its inadequacy in preventing the recurrence of relapses. Innumerable observations were made both at the base and in corps areas with the object of testing the value of quinine in relapse prophylaxis. Many of these have been published, and I wish here only to allude to the results obtained by Major A. G. Anderson, R.A.M.C., in the special malaria wards set apart for observation purposes at a base general hospital. In these wards the best results in the prevention of relapses were obtained by the so-called week-end system, in which 30 gr. of quinine were given on each of two consecutive days in each week. By this method the percentage of non-relapse cases was increased to 78 per cent., as compared with 32 per cent. in the control series, in which no quinine was given after the initial pyrexia had subsided. No inconvenient symptoms arose from the larger week-end doses in the case of patients treated in hospital, but equally good results may be obtained by the same weekly quantity of quinine distributed in daily doses of 10 gr. for six days a week, a plan of treatment which has undoubted advantages in the case of individuals who are occupied in their daily work, as has been pointed out by Sir Ronald Ross in a recent communication to THE LANCET (Jan. 3rd).

BILHARZIASIS:

ITS INCIDENCE AND ERADICATION.

BY FRANK MILTON, M.R.C.S. ENG., L.R.C.P. LOND.,
LATE PROFESSOR OF CLINICAL SURGERY, GOVERNMENT SCHOOL OF MEDICINE, CAIRO.

IN THE LANCET of Oct. 11th, 1919, a paper under the above heading appeared, written by (Mrs.) B. Sheldon Elgood and Major Thomas Cherry, the main points of the paper being: 1. The absence of schistosomiasis from Crete and its presence in Cyprus is due to the free flow of the mountain streams during the summer in the former and the presence of marshes and streams nearly dry in the summer in the latter. 2. The festival of Shem-en-Nesim is the occasion and cause of the infection of the population of Cairo with schistosomiasis, and accounts for the recognised age-incidence of the disease, it being known to occur with greatest frequency among children above the age of infancy and in young adults. 3. Schistosomiasis might be eradicated from Egypt were flocks of ducks kept in the infected districts and directed by the children to the portions of the canal known to harbour infected molluscs.

The first proposition is interesting, but it must be remembered that both the molluscar hosts and the cercaria of the schistosomidæ have great capabilities of adaptation, being even able to thrive in the hot springs at Gabes in Tunis, where the temperature of the water is over 40°C., and it is quite possible that it is not the disease that is wanting in Crete but its recognition. The second contention is of greater interest, and opens up a much more important question. It may very well be that many Cairene children are infected at Shem-en-Nesim, although opportunities for them to become infected at garden pools, fountains, and the Khalig are plentiful throughout the year; but one may well question whether the age-incidence is due to so simple a cause. Shem-en-Nesim is essentially an Egyptian festival, but inquiry will show that the age-incidence of schistosomiasis is world-wide. Wherever the disease is endemic in a high degree—i.e., wherever the chance of infection is constantly present at all periods of life—the greater number of cases of schistosomiasis will be found to occur in advancing childhood and early youth, whilst mature adults are comparatively free; at the same time, the cases among the young population are mild in degree and present but simple symptoms, whilst the majority, if not all, the cases among adults are by comparison severe and show a complication of symptoms.

In running one's mind back over the many hundreds of cases seen in hospital and private practice in Egypt, one finds it hard to recall any but cases of simple hæmaturia in the young or any but severe cases of cystitis, proctitis, fistula, and so on, in mature adults. I am speaking now, of course, of native Egyptians who have passed their lives in the midst of potential infection.

That the age-incidence is the same in all parts of the world is shown by the records of Thomson[1] in the Eastern Soudan; by Conor[2] and Conor and Benazet,[3] amongst others, in Tunis; by Clapier[4] on the West Coast of Africa; by Allen[5] and Petrie[6] in Natal; by Turner[7] at the Cape and in the Transvaal; by Leger[8] in the West Indies; by Ris-quez[9] in Venezuela; by Gonzales[10] in Porto Rico; by Edgar[11] in China; and by Fujinami[12] in Japan. Spring-time festivals, such as Shem-en-Nesim, are universal, but it must need some much more profoundly acting influence than annual excursions of the townspeople into the country to bring about a condition characteristic of a particular disease throughout the world, and I think that this influence in the case of schistosomiasis is that of acquired immunity.

Evidence of Acquired Immunity in Schistosomiasis.

The only direct experiment to prove the acquisition of immunity in schistosomiasis that I am aware of was that of Fujinami,[12] when he used the horse, and when he obtained results which were more than suggestive. But, after all, experiment is hardly necessary when we clearly see the process going on in nature before our eyes.

Take the case of the Egyptian peasant, the greater part of whose life is passed in direct contact with cercaria-bearing water. He acquires the disease early in life, passes blood in his urine for so many months, or it may be for a few years, and then this ceases and he is spontaneously cured, and not only is he cured of this attack but his history will show that although he continues to expose himself to reinfection throughout the remainder of his life he never again suffers from hæmaturia or reacquires the disease. This is the history of the vast majority of the natives of Egypt, but, as we know only too well, there are cases, in great numbers, in which the disease, instead of undergoing spontaneous cure, progresses and shows signs, as it were, of malignancy, lasting for the remainder of the victim's life, and eventually, it may be, killing him.

Between these two extremes, the simple uncomplicated case of hæmaturia going on to spontaneous cure and the progressive case going on to death, there is every grade of duration and severity. These cases show that complete immunity is not acquired in every case and that there are individuals whose resistance is strong and rapidly developed and others less capable of resistance and who do not react defensively to the toxins elaborated by the parasites.

Pathologically the agglomeration of multinuclear cells, stellate cells, and eosinophiles in the bilharzial tubercles found in the liver and elsewhere wherever eggs are lodged, and the excessive formation of bilharzial granulation tissue occurring in connexion with old-standing bilharzial lesions, point to the local action of a toxin generated in the vicinity of deposited eggs. The general systemic disturbance, the fever, and the urticaria exhibited during the early weeks after infection by any of the three species of schistosomes point to the general action of a toxin produced by the parasite. The great increase of the eosinophile elements of the blood during the early months of infection probably indicate the effort of the organism to resist the action of this toxin and to produce immunity to its harmful effects.

In 1916 Fujinami[12] showed that a horse which had recovered from schistosomiasis failed to acquire the disease a second time when experimentally exposed to infection, whilst two other horses, which had never had the disease and were exposed to infection under identical conditions, both became heavily infected.

Sueyasu,[13] working on the blood of this first "immune" horse, obtained a positive complement-fixation, with both an aqueous and an alcoholic antigen.

Last year Hamilton Fairley,[14] in his own words, "adduced definite evidence of an immune body in the sera of patients affected with either the *Sch. hæmatobium* or the *Sch. mansoni* type of Egyptian bilharzia."

If immunity be acquired by an attack of schistosomiasis the disease, in a country where the disease is endemic and where the mass of the population is constantly exposed to the risk of infection, would naturally tend to become a disease of early life exactly as the ordinary zymotic diseases are in England, and as few of us escape in our early years, so do few Egyptians escape schistosomiasis during their youth.

All helminthic infections appear to give rise to some general disturbance of the system of the host, and it is highly probable or, as I venture to think, certain that each helminth produces its own toxin, which is absorbed by its host and sets in train changes which lead to immunity not only against further harmful effects of the toxin, but render the tissues of his body inimical to the parasite itself. These changes not only lead to the death of the original parasites, but prevent the development and growth of any other parasite of the same specie, the immature forms of which may have gained entrance to his body. Were this not so, the fellaheen of Egypt, who are constantly in contact with water containing *Schistosoma cercaria*, would be accumulating new schistosomes throughout their lives, and they would of necessity suffer from the effect of the infection in an increasing degree as their age increased instead of the disease being, as we know it is, one essentially of early life.

The idea of introducing flocks of ducks to eradicate bilharziasis from Egypt is ingenious, but it must be remembered that ducks themselves are liable to attack by *Bilharziella polonica*, and one wonders what would be the result if the village children, either through defective instruction or mere devilment, instead of leading their charges to the beds of *Bullinus contortus* hurried them to the haunts of *Planorbis mareoticus!*

Coonoor, S. India.

THE ABUSE OF PASSIVE MOVEMENTS.

BY E. STANLEY BRENTNALL, M.B., CH.B.,
F.R.C.S. EDIN.,

SURGEON, SPECIAL MILITARY SURGICAL HOSPITAL, GRANGETHORPE; MEDICAL OFFICER IN CHARGE, MASSAGE AND ELECTRICAL DEPARTMENT, ANCOATS HOSPITAL, MANCHESTER.

THESE remarks are an attempt to accentuate certain widely enunciated principles of treatment which have long been taught by well-known experts in orthopædic surgery, but which, frequently owing to want of interest, are ignored.

It is common for a patient suffering from the results of an injury or disease which has been treated by prolonged immobilisation in splints or otherwise to be referred to a treatment department for "massage and passive movements." This phrase may be seen in the majority of recommendations for treatment brought in from their local committees by pensioners—wounded at least over a year ago—to their treatment clinics. This class of case includes, among many others, conditions such as ankyloses, fibrous and bony, following injury and infection of joint surfaces; muscle and tendon injuries with destruction and fibrous replacement of contractile material, and consequent contractures, or deep-seated matting and adhesions; chronic irritative conditions of bones, joint surfaces or nerves, with resulting reflex spasm; internal derangements of joints with muscle atrophy. In addition, there are the countless simpler injuries, of varying severity, of the bony or soft parts of a limb with accompanying stiffness of joints and restriction of their full range of mobility.

In the treatment of such conditions it is obvious that in some, for example the flaccid knee, passive movements will be useless; in fact, the ultimate aims of treatment here, after the removal of the immediate cause of the derangement, are the provision of a sufficiently active musculature surrounding the joint to control or prevent undesirable passive mobility. In other cases passive movement will be mechanically impossible.

For the relief of such incapacity as is due to actual muscle injury and fibrous replacement, the only possible hope lies in the development by continuous, unwearying encouragement and training—assisted possibly by external stimulation, such as the faradic current—of a voluntary shortening of the muscle substance remaining. This muscle must be singled out individually and "put through its paces" according to a definite scheme of work depending on its capacity. Such individual exercise is a vital introduction to the subsequent training and development of the function of the limb, in which all muscles are made to act in team according to their physiological arrangement.

Limitation of joint movements by contractures derives no benefit whatever from passive movements. In certain cases stretching a joint is of the utmost service, but this is a very far cry from moving it passively. The limb, after a preliminary course of massage, is firmly and evenly stretched, the patient the whole while being exhorted to assist in such movement to the utmost of his capacity. Following this it is replaced in an apparatus designed to exert a constant pull on the shortened structures, and not removed till the treatment is repeated.

Among the uncountable varieties of joint injuries there are of course some which are ameliorated during the course of their treatment by movement through the whole joint range once or perhaps twice. This is, however, only possible in the complete relaxation of surgical anæsthesia, and is then only to be undertaken by the surgeon as a manœuvre from which he can date the beginning of his active joint movements.

Early Voluntary Movements in Recent Infective Conditions.

These remarks, made in reference to disabilities of long duration, are equally true if applied to recent infective and traumatic conditions. It has been very forcibly pointed out by Osgood and others that even in the acute stage of pyogenic joint infections early voluntary movements (first of all simply efforts at movement) on the part of the patient by no means tend in suitably selected cases to increase the disturbance, and vastly influence the future possibilities of the function of the limb. In such conditions passive movements need not be considered.

In early traumatic lesions, when the moment for mobilisation has arrived—and this should not be delayed longer than the acute manifestations or questions of fixation render imperative—voluntary muscular contraction, accompanied by joint movement, holds its place of maximum utility. All the theoretical advantages claimed for massage are immediately and efficiently secured; dangerous areas are avoided automatically; exudates are absorbed; troublesome adhesions and dense infiltration are prevented. No doubt it may be advisable in some cases at the first visit of the patient to demonstrate passively to him the nature of the movement to be produced. This, however, is not treatment by "passive movements"; it is a method of overcoming reflex inhibition of voluntary muscular control. Joint movement can be obtained with infinitely more gratification to the patient actively than by passive treatment, and with complete safety if nature's danger signals of pain, swelling, and stiffness are watched.

Dangers of Passive Movements.

Passive movements, on the other hand, carry with them no guarantee of safety; they are often accompanied by acute uneasiness in the mind of the patient; they have little physiological value from a vascular and trophic point of view; they are often rendered quite impossible by reflex rigidity and stiffness, or if strict attention to the orders of the prescribing authority is conscientiously paid, the passive resistance of the patient is overcome and serious harm is done. In this way slumbering infection or trauma is wakened, and new complications, such as cicatricial and bony overgrowth in the neighbourhood of the lesion, are produced. Unfortunate examples of the result of "early massage and passive movements" are constantly seen in the elbows of patients with injuries to the lower extremity of the humerus. Tender, stiff, and swollen, they are subjected to continual pulling and pushing till permanent and irrevocable damage has been done to the limb; while the alternative treatment of a short, full-flexion, wrist sling, with active elbow movements following the disappearance of the acute manifestations, would have almost certainly restored to the limb in a comparatively short time a good, if not a full, measure of functional capacity.

It is not denied that, judiciously applied, passive movement is occasionally of service, but it is only so in the hands of a surgeon who, for a reason that he is prepared to define, after eliminating resistance, produces the desired movements. It is certainly not so when applied indiscriminately on all and sundry injuries to the limbs.

Summary.

It is time that the phrase "massage and passive movements," as loosely indicating a form of treatment on to which responsibility for future failure may be thrown, should disappear for ever. While of value in a few cases, not only is it useless as a routine therapeutic measure, but in many cases it does definite and positive harm. It is for these reasons that machinery of the Zander type has been excluded from up-to-date physio-therapeutic departments. Voluntary movement, on the other hand, whether reinforced externally or not, undertaken at the right moment, is a valuable method of treatment, physiologically correct, carrying with it its own guarantee of safety.

It is considerations such as these that emphasise the necessity of a single control—that of the surgeon—over the treatment of a patient, no matter whether in the out-patient department, the

ward, the massage and electrical department, or the gymnasium. The surgeon responsible for the ultimate restoration of the patient to his maximum degree of capacity should be responsible also for the treatment the patient receives in the various departments of the hospital. There is no doubt that the system of "watertight" departments with separate heads is to be held to blame for a certain degree of permanent disability following injuries.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF SURGERY: SUBSECTION OF PROCTOLOGY.

RESUMED DISCUSSION ON DIVERTICULITIS.

A MEETING of this section of the Royal Society of Medicine was held on Jan. 14th, Mr. J. P. LOCKHART-MUMMERY, the President, being in the chair, when the adjourned discussion on Diverticulitis was resumed.

The PRESIDENT said that diverticulitis was an important clinical condition, and was not so rare as was at first supposed. Its greatest importance lay in the fact that it was easily and frequently confused with cancer of the sigmoid or rectum, and was nearly always mistaken for inoperable cancer because the tumour was large and fixed by adhesions. Unless complete obstruction was present, therefore, the patient might be left until serious septic conditions had arisen and it was too late to benefit him by operation. Diverticulitis might be diagnosed from cancer by (1) the occurrence of acute inflammatory attacks, with high temperature and rigors; (2) the absence of blood in the stools; (3) the absence of secondary deposits after some long period. Perforation of the bladder had occurred in 4 of his 24 cases, accompanied by acute cystitis and rigors, flatus and fæces being passed per urethram. He had never seen actual perforation of the bladder from cancer of the intestine. In his series there were two cases of secondary carcinoma supervening upon an old diverticulitis, no evidence of malignancy being present at the time of operation. He attributed the malignancy to the irritation of the chronic sepsis which existed in and around the diverticula, and, bearing this possible danger in mind, if septic symptoms were present colostomy should be performed as soon as possible. From a study of Mr. Grey Turner's specimen he thought it possible that the diverticula had developed above the growth as the result of the stricture caused by the growth, so that diverticulitis might occur secondarily to carcinoma of the bowel, as well as the reverse. With regard to treatment, he strongly urged that the operation of choice in diverticulitis was colostomy above the obstruction, or short-circuiting it, and that only in exceptional circumstances should an attempt be made to do primary resection of these highly septic tumours. The results of colostomy were very satisfactory. If the disease had not progressed too far it became completely arrested after colostomy, and the patient regained normal health.

Mr. W. ERNEST MILES said that it was not easy to determine whether diverticulitis was a new form of disease due to modern modes of life or one which had existed throughout the ages. He did not think the condition was congenital. A more likely cause was increased intra-colonic pressure, the diverticula being hernial extrusions of the mucosa through the muscular coats of the bowel at the weak points created by the passage of blood-vessels. Anything, therefore, which increased intra-colonic pressure was a possible ætiological factor. In every-day life intra-colonic pressure might be increased in three ways. (1) Forcibly resisting the desire to evacuate the bowels. (2) Straining at stool, such as when a formed motion is passed through a narrowed anal orifice, as occurs from stricture of the rectum or from a deposit of fibrous tissue in the submucosa of the pecten, as described by the speaker in an article entitled "Observations upon Internal Piles."[1] The presence of the pecten band is shown by difficulty in emptying the rectum during defæcation, and by the diminished calibre of the fæces passed. (3) The habitual use of copious enemata.

Dr. A. C. JORDAN showed a number of X ray photographs. He considered that colitis was the cause of diverticulitis. The catarrhal state of the mucous membrane induced tight haustral constriction of the bowel, with exaggerated sacculation between the haustra. After some years this condition became permanent, the haustra never relaxing and the lumen of the bowel never opening up fully. Small-celled infiltration then occurred, which led to the formation of a tumour. The saccules must then lose their muscular coat, for: (1) the whole bowel is fatty and sodden; (2) the circular muscle, being in a state of spasm, cannot remain on the sides of the saccules, but must become retracted down to the bowel wall at the base of the saccules; and (3) the muscle layer over the distal end of the saccule is attenuated by pressure from within the bowel, and must be absorbed gradually, leaving perhaps a vestige, such as had been described by more than one speaker. The catarrh itself was due primarily to stasis in the large intestine, secondarily to microbic infection. Other pressure sacs, comparable in origin with those of the large intestine, occurred in the œsophagus: (*a*) at the upper end—the pharyngeal pouch—and (*b*) just below the bifurcation of the trachea—the digital pouch. In the bladder also, when there was a urethral stricture in stout elderly men, multiple diverticula occurred with small orifices protruding through the muscular coat. Such cases were described by Sir Arbuthnot Lane in 1884, and published by him in Guy's Hospital Reports for 1886.

Dr. F. HERNAMAN-JOHNSON laid stress on the presence of small round barium masses in clusters after evacuation of the meal or enema as a whole as the most satisfactory radiological evidence of the existence of permanent diverticula. The appearance was characteristic, and never, so far as he knew, mimicked by spasm or chance residues. Should diverticulitis be suspected, but not revealed by a meal, the administration of belladonna to the limit of tolerance for 36 hours, followed by thorough cleansing of the lower bowel by oil enemas, greatly increased the chance of demonstration by a barium clyster. In fact, the same care should be taken to secure patency of the diverticula as is done in the case of the appendix when it is desired to show it by X rays. The administration of belladonna had also the advantage of relieving many forms of spasm which might otherwise lead to a suspicion of organic stricture.

Perforating Diverticulitis of the Iliac Colon.

Mr. L. E. C. NORBURY described a case of Perforating Diverticulitis of the Iliac Colon in a woman aged 43. There was a history of constipation for 15 years, an attack of diarrhœa 11 years previously lasting one month, and severe griping pains for six months. On examination a swelling was detected in the left iliac region; it proved to be an adherent mass connected with the iliac colon and closely simulated carcinoma. The affected portion of the intestine, some 5 or 6 in. in length, was removed. The ends were closed and a lateral anastomosis made. The result was successful. When the specimen was examined it was found that the gut was much contracted; its walls were greatly hypertrophied and contained fatty tissue in abundance. At one place there was an irregular cavity in the fat communicating with the lumen of the gut and due to perforating diverticulitis. When first examined the cavity contained pus and pellets of inspissated fæcal matter. Microscopically there were all the signs of acute and chronic inflammation, but no evidence of malignant disease. Mr. Norbury considered enterospasm a predisposing cause of diverticulitis by producing hypertrophy of all the coats of the bowel. Constipation followed and the bowel wall became weakened at certain points owing to excessive pressure and infection. In such cases the diverticula would be pressure diverticula. The diverticula might be multiple or simple. A section through the wall showed a well-marked muscularis mucosæ and mucous membrane with Lieberkuhn's glands. The wall might give way with resulting infection of the surrounding fat, which was usually superabundant. Sigmoidoscopy might be of value in certain cases. The lumen of the bowel, in this condition, was very much narrowed. He had seen some cases in which the pelvic colon narrowed as the result of spasm and hypertrophy, and it was in such cases that diverticula might be expected to be present.

---

[1] Surgery, Gynecology, and Obstetrics, November, 1919.

Sir **CHARTERS SYMONDS** asked what symptoms, if any, indicated the various stages in the process of communication with the bladder. What would lead one to suspect that communication between a diverticulum and the bladder was a possibility or was imminent? He had seen patients who suffered from pain when the bladder was full, the pain being completely relieved when the bladder was emptied. In these cases pain was also associated with the act of defæcation.

The **PRESIDENT** said that when a communication occurred between a diverticulum and the bladder the symptoms came on suddenly and unexpectedly.

Reply on the Discussion.

Dr. **MAXWELL TELLING**, in his reply, said that the name "sacculitis" was likely to cause confusion between the condition under discussion and sacculation of the colon. The name "diverticulitis" had passed into current use and now served to differentiate the condition from sacculitis. He thought that after middle life diverticulitis would be found to be of considerable frequency. Only a small proportion caused symptoms or gave rise to trouble. A distinction should be drawn between diverticula and diverticulitis. No operation was necessary unless clinical symptoms occurred. Much more work needed to be done before we could rely on X ray findings. The appearance was deceptive in some cases, and we should be careful not to apply the term diverticulitis to a condition of dilatation of the colon in spasm. The relationship of the condition to malignant disease was twofold. In some cases carcinoma developed after diverticulitis, whilst in others diverticula formed round the constriction of carcinoma.

Exhibition of Illustrative Specimens.

A number of illustrative specimens were on view, among which were the following:—

Mr. W. **SAMPSON HANDLEY** exhibited a specimen of Diverticulitis of the Small Intestine produced by traction, after adhesion of the intestine to a tuberculous retro-peritoneal gland. The gland was dragged from its bed, and had formed a band strangulating an adjoining coil, and causing acute obstruction. The patient, a boy aged 6, recovered.

Mr. C. A. R. **NITCH** exhibited part of a Pelvic Colon which was excised for the results of perforating diverticulitis. The patient, a woman aged 49, had suffered from constipation for many years. In November, 1919, she had an attack of colicky pain in the lower part of the abdomen, accompanied by constipation and tenesmus. A fortnight later she had a similar attack, with slight rise of temperature, and passed some blood and mucus. On examination an oval mobile tumour was felt just below the brim of the pelvis on the left side. At the operation the tumour, thought to be carcinoma, was resected, and the continuity of the bowel restored by axial anastomosis. The patient made an uneventful recovery. Examination of the specimen revealed the presence of three diverticula, one of which opened into an irregular cavity of necrotic and suppurating pericolic fat. Microscopic examination showed that the fat around the necrotic area was thickly infiltrated with polymorphs and was hyperæmic.

Dr. F. **HERNAMAN-JOHNSON** exhibited X ray Photographs of a case of Diverticulitis in a woman aged 60. The plates showed: (*a*) by opaque meal, a few rounded shadows external to the main mass of the meal in the sigmoid; (*b*) by opaque enema in situ, very similar appearances; (*c*) after evacuation of the enema, numerous round discrete shadows remaining in the region of the sigmoid. It was the last appearance which led to his regarding the case as one of diverticulitis, and this was confirmed at operation.

SECTION OF PSYCHIATRY.

THE NATURE OF EPILEPSY.

A MEETING of this section of the Royal Society of Medicine was held on Jan. 13th. In the absence of the President and Vice-Presidents, the chair was taken by Dr. **PERCY SMITH**. On the conclusion of formal business the **CHAIRMAN** called upon Dr. E. W. **SCRIPTURE** to read a paper on the Nature of Epilepsy.

Melody Curves.

This paper was in reality a description of a particular method of investigation and its relation to a particular theory of the ætiology of epilepsy. Dr. Scripture first demonstrated with the aid of the epidiascope his apparatus for recording on a smoked drum the variations of pitch in the melody of normal human utterance. He explained that in addition to the normal variations of pitch there were also minute variations which the naked eye was not capable of recognising, but which were revealed by magnification. These finer undulations, measured vertically from crest to trough, showed a variation of frequency of from 100 to 130 per second. The trained ear was able to detect the absence of these secondary undulations, so that Dr. Scripture found himself able to recognise an epileptic subject—in which these secondary variations are absent—simply by listening to the sound of the patient's voice.

Pierce-Clark's Theory of Epilepsy.

He had for several years been unable to account for this inflexibility of the epileptic voice, until he read a theory of the psychogenesis of epilepsy advanced by his old colleague, Dr. Pierce-Clark. This theory states: (1) That the epileptic subject is a combination of the hypersensitive and of the egocentric, which results in a being ill-adapted to the normal environment of man; (2) that he is at the same time stubbornly determined that his environment shall be made to conform to himself; and (3) that the continued strain resulting from his inability to conform to environment is the root cause of his epilepsy. Freedom from conflict is found in unconsciousness.

Dr. Scripture, in supporting this theory, did not hesitate to put forward the life-history of an egocentric dog as an evidence of its probability. The dog's epilepsy only appeared when it was prevented from indulging its every whim. Now the melodious voice is used by that man who is anxious to please. Was it not natural to suppose, therefore, that the unmelodious wooden voice of the epileptic was symptomatic of his essential egocentricity?

Discussion.

Sir **ROBERT ARMSTRONG-JONES** could not find any reason for giving credence to the Pierce-Clark theory of the origin of epilepsy. So many found it difficult to conform to their environment who were yet not epileptic. On the other hand, he thought that Dr. Scripture's apparatus might prove very valuable as an instrument of special diagnosis if it could be shown that certain distinct varieties of melody curve were characteristic of different diseases.

Dr. **BERNARD HART** asked whether such special curves had been shown to exist. He also inquired whether the wooden tone of the stutterer was attributed by Dr. Scripture to the same psychological cause—i.e., egocentricity—as in the case of the epileptic.

Dr. **HELEN BOYLE** was anxious to know whether the cases investigated by Dr. Scripture were being treated with bromides. She believed there were three or four varieties of epilepsy, some curable, some incurable, and some curable under certain conditions and not under others.

Dr. **SCRIPTURE**, in reply, said that it was only those who were uncompromising in their resistance to adaptation who became epileptic. He had found curves characteristic of general paralysis, and was still working upon the curves in dementia præcox. The monotony in stuttering was due to an absence of all voice modulation. In epilepsy the voice is modulated, but the finer variations in frequency are absent. The cases upon which his investigations were carried out had been carefully selected from among patients who had not been treated with bromides. He agreed that there were different varieties of epilepsy.

THE ENDOCRINE GLANDS AND MENTAL DISORDER.

Dr. H. CRICHTON MILLER read a paper on the Rôle of the Endocrine Glands in Mental Disorder. He gave a broad survey of his subject, and dealt with an amazing volume of literature that has been written on the subject. The close inter-relation of psychic and somatic (endocrine) factors in the production of mental disease was illustrated (among other ways) by a discussion of obsessional hypertrichosis. The overgrowth of hair was clearly due to physical changes, but the effect of the realisation of this overgrowth on the mind of the patient clearly resulted in psychic strain. Hypothyroidism influenced the creative even more than the reproductive faculties. Who has ever conceived of a myxœdematous artist? He expressed himself as a firm believer in the psychogenesis of maniac-depressive insanity, yet the regular periodicity evidenced in the phases of this disease must be due to physiological fluctuations. There was here, again, a psycho-physical interaction. Discussing the present empirical methods of treatment with extracts from the ductless glands, Dr. Miller remarked that we stand at the present time between a moderately successful endocrine therapy on the one hand and a vast quantity of uncorrelated laboratory experience on the other. Endocrine disorders might be forestalled (*a*) by early psychopathic treatment, (*b*) by early treatment of septic conditions. At present we attempted neither method. We must learn therefore to repair the damage wrought by the resulting disharmony of the endocrine secretions. This link in the chain of disease was capable of approach both from the mental and physical side. Dr. Miller discussed in detail five possible relationships between the psychic and endocrine systems. As an example of how both psychic and endocrine influences might combine to upset mental equilibrium, he cited the case of a girl patient which had come under his notice. In the space of four months she had been treated successfully by no less than three mental specialists—a psychoanalyst, a believer in suggestion, and, finally, one who believed in the power of his own personality to set the patient straight. At the end of that time she was in so serious a condition that it seemed almost necessary to sign a certificate. Certainly there were psychic factors involved. Her fiancé was a man who had been jilted by her sister, the pleasure she took in being petted at home also made the idea of marriage distasteful to her. But where psycho-therapy had failed a course of treatment with thyroid extract proved successful. The increase in sexual desire resulting from this treatment proved a natural solution of the mental conflict. She was happily married and completely cured.

Discussion on Dr. Miller's Paper.

The CHAIRMAN remarked on the difficulty of following so intricate a subject without having first been able to read a digest of the paper. Dr. Miller appeared to have transferred the conflict into the endocrine system.

Dr. LEONARD WILLIAMS agreed with such parts of Dr. Miller's paper as he felt it within his capacity to criticise. He cited a case of thyroidectomy in which the patient had been unable to take the form of thyroid extract offered her after the operation. Nor were grafts of the gland introduced into the abdomen any more successful. A certain liquid preparation was at last found to be satisfactory in every respect except one. The patient, either in hot summer weather or when seated before a large fire, was subject to a severe sense of chilliness. This was overcome by adding extract of parathyroid to her medicine.

Dr. HARRY CAMPBELL also expressed agreement with the paper. It was one of his aphorisms that the temperament of man, be he pleasant or surly, was due to the composition of his blood. This was true of the congenital psychasthenic and neurasthenic, and the psycho-analysts would eventually find themselves up against this fact. They might solve temporary difficulties by analysis, but they could not change a temperament which had its origin in the chemical constituents which make up the plasma.

Dr. MILLER, in reply, feared that he had not made his thesis clear. He did not really transfer the conflict to the endocrine system. He wished the interaction of the two systems upon each other to be recognised. Dr. Campbell had quoted two examples to show the pre-eminence of the internal secretions. With one of these, the periodical coming into rut of the stag, Dr. Miller agreed—the very periodicity was evidence of a physiological basis. The other example was of the apparent rejuvenation of an aged arthritic dog when living in contact with a bitch during the period of "heat." But this case surely was an example of physical change wrought by psychic stimulation, though the psychic stimulation might very probably be aroused in the first case by an impulse travelling along the olfactory nerves.

TUBERCULOSIS SOCIETY.

RESUMED DISCUSSION ON TUBERCULOSIS IN RELATION TO SCHOOL LIFE.

THE second joint meeting of the society with the Society of School Medical Officers took place on Jan. 12th, with Dr. JAMES KERR in the chair, when the discussion upon "The Various Aspects of Tuberculosis in Relation to School Life" was resumed.

Dr. F. W. HIGGS said that the subject must be viewed from both the clinical, pathological, and from the administrative aspects, and was full of possibilities of research. The presence of an active granuloma in the body was bound to produce symptoms even though diagnostic signs were absent, and every child who did not get on should be suspected of an active focus. These children should be weighed every month until there had been a steady increase for some time. They should be kept under observation by the school medical officer, and doubtful cases referred to the tuberculosis officer. He thought that these officers, if they had not already acquired it, should be given time to increase their knowledge of the subject by the local body which employed them. Radiologists until they became expert were apt, in his opinion, to diagnose tubercle in every case. The following measures were essential to reduce the disease: refusal of admission of tuberculous aliens into the country; isolation of open cases; dustless streets and houses; clean milk; every school an open-air school; education.

Dr. JANE WALKER objected to the stigma which was inevitably placed upon children by the necessity of notification before institutional treatment could be provided. This proved a great handicap to the child in later life and we should be careful before we damned them by this statement. She did not agree with many authorities who stated that once tubercle bacilli had been found in the sputum the cases could not be cured; her experience had been more hopeful. She did not think that household work was an unsuitable occupation for an ex-patient, if the hours were moderate and the meals regular and good. She had been in the habit of employing ex-patients from her sanatorium at Nayland and in one case this had evoked hostile criticism from the London County Council. She kept children as long as possible in sanatorium because if they returned home their education was entirely neglected. Tuberculous children were above the mental average—quick, clever, shallow, and sharp as a needle; they soon became educationally normal under tuition. She thought that continuation residential schools would be necessary when the new Education Act came into force.

Dr. MARCUS S. PATERSON was glad to see the union of the two societies over such an important subject, as it was evidence of team work, which in tuberculosis was so essential. He thought that the word "fresh-air" should be substituted for "open-air" in speaking of schools.

Dr. JAMES WATT said that tubercle in childhood was without doubt the forerunner of tubercle in the adult. Cases should, therefore, be recognised in childhood, which later might become adult cases, and they should be kept under supervision by the various officers of the public health services. There were two methods of doing this—to examine the whole population at intervals, and to pick out all delicate children at school and follow them up. He did not recognise a subtuberculous stage; either the disease was or was not present. He urged the noting of observations in daily routine, so that definite research resulted.

Mr. F. J. C. BLACKMORE said that it was impossible for efficient work to be done with the present staff at the dispensaries, who could not cope with the numbers. The Welsh National Memorial officers had recently discussed the subject and resolved that eight new cases and 24 old cases were as much as any one man could do at one sitting.

Dr. D. J. WILLIAMSON thought that the school medical officer was under extreme difficulties in diagnosing tubercle owing to the noise and the short time allowed for each examination. He did not treat cases at the dispensary until the diagnosis was confirmed.

Dr. A. D. REID considered X ray a very valuable aid to diagnosis. Every child, however, which showed shadows in the chest was not a case for sanatorium. X rays must be taken in conjunction with symptoms and was then a great adjunct.

Dr. F. C. SHRUBSALL said that education and food were the two most important factors—education, because upon it the later earning capacity of a good living wage entirely depended.

Dr. KERR said that his ideas had been considerably modified by the discussion. Standards of efficiency now seemed doubly essential, and more attention should be paid to the pure-air campaign in schools.

The following resolution was passed:—

> That it be referred to the Councils of the two societies to appoint a joint committee to consider the whole subject and to report to the two societies.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—At a clinical meeting of this society, held on Jan. 9th, with Mr. Herbert Chambers, the President, in the chair, Dr. A. C. Warren showed for Dr. F. S. Palmer a case of General Paralysis which had been trephined and for which salvarsanised serum had been injected into the ventricles of the brain. The patient, a man of 37, had had five intracranial injections into the lateral ventricles by Sir Charles Ballance at the West End Hospital for Nervous Diseases. He had also four intrathecal injections of the same serum, with the result that the cell count in the spinal fluid had been very much reduced, and the mental and physical condition of the man had considerably improved. Before treatment he had cerebral and other symptoms. His memory was impaired, he was violent at times, and had great difficulty with his speech. He required assistance in walking, tremor was very marked, the pupils were unequal and failed to react to light, and the Wassermann reaction was positive. The man had shell shock during the Battle of Jutland, May 31st, 1916, and was invalided from the navy in November, 1917. He married in February, 1918, but his wife had no children and no miscarriages. In the subsequent discussion Sir Robert Armstrong-Jones did not agree that there had been any improvement in this particular case, and said that the case presented every evidence of rapid deterioration, and went far to confirm his experience. He had personal knowledge of over 330 cases of general paralysis at Claybury, and the average duration was one year and four months from the date of admission, and possibly the symptoms had been coming on for a month or two, perhaps longer, before admission. He had also personal knowledge of six cases, similar to the one shown, treated by direct intracranial injections, five had already died, and the sixth was regressing. He did not think that surgical treatment of this kind was going to cure or even relieve confirmed cases of cortical parenchymatous spirochætosis; the neuronic damage had already been done and was irreparable. He agreed that there was a great difference in the treatment of syphilitic disease of the cerebral arteries and the meninges with inflammatory symptoms and the presence of polymorphonuclear leucocytes and the treatment of parenchymatous syphilis with the presence of lymphocytes. Sir Robert Armstrong-Jones referred to cerebral seizures of a temporary character as occasionally the first symptoms of general paralysis, and in these cases he had sometimes found ergot useful. He had also seen marked improvement in two cases by thorium hydroxide, although symptoms of general paralysis might remit for long periods without any treatment except rest.—Dr. J. F. Halls Dally drew attention to the importance of complete examination of the cerebro-spinal fluid. If the Wassermann only is done the result might be negative, and therefore extremely misleading, whereas examination of the cerebro-spinal fluid was likely not only to give positive evidence, but also to afford an indication as to the activity of the syphilitic process at the time of examination.—The case was further discussed by the President, Lieutenant-Colonel E. M. Wilson, Dr. Arthur Saunders, Dr. J. Burnford, Mr. Rickard Lloyd, and Dr. Stanley Wyard.—Dr. A. C. Warren also showed for Dr. Palmer a case of Disseminated Sclerosis in a man, aged 23, and Dr. Burnford showed cases of (1) Syphilitic Meningitis; and (2) Exophthalmos in a boy of 16.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—At a combined meeting of this society with the Nottingham Division of the British Medical Association, held on Jan. 7th a lecture on Modern Methods of Treatment in Functional Nervous Disorders was given by Dr. Bernard Hart. The lecturer began by pointing out that the term "functional nervous disease," under which were grouped hysteria, neurasthenia, and various allied conditions, including the great majority of the disorders to which the name "shell shock" was applied during the war, was rapidly becoming obsolete, and was being replaced by another term, "psycho-neurosis." Behind this change in nomenclature there lay a revolution in our conception of the nature of these disorders, and of the treatment applicable to them. This revolution consisted in the advent of the psychogenic theory, which maintained that the so-called functional nervous diseases were due predominantly to causes of a psychological order, and that their treatment must therefore be carried out, in great part at least, by psychological methods. The lecturer outlined the historical development of the psychogenic theory which had taken place since the time of Charcot and the numerous apparently divergent schools and methods of psychotherapy which had thus arisen. These divergences were so obvious that it was easy to overlook the fact that all the methods were built upon a common basis. This common basis consisted in the psychogenic theory, and if its broad principles were kept constantly in view the relative merits of the various methods could be estimated and their applicability and promise of success determined in each individual case. It was clearly necessary, firstly, to determine what psychological factors were playing a part in the causation of the condition in question, and, secondly, to employ methods of treatment which would remove these factors or so modify them that the disorder was no longer produced. These two processes could be termed "analysis" and "rectification." Analysis involved a knowledge of the motive forces of the mind and their mode of action, a knowledge of psychology and psycho-pathology, so that the nature of the causal factors could be deduced from the symptoms present. Rectification included suggestion, persuasion, re-education, and the employment of all the emotional or instinctive forces which could be called to our aid to modify the mental processes of the patient in the desired direction. Dr. Hart illustrated the application of these principles to various types of psycho-neurosis, selecting a series of cases of increasing complexity, and including such conditions as functional dyspepsia, hysterical paralyses and mutism, and the so-called "anxiety neuroses." In conclusion, he pointed out that, although in the course of the lecture he had emphasised the psychological factors and their treatment, because the recognition of their importance constituted the fundamental feature of modern conceptions, yet it was urgently necessary to take account of the physical factors which also played a part in the psycho-neuroses, and to deal with them by suitable methods.

THE ASSURANCE MEDICAL SOCIETY.—At a special meeting of this society, held on Jan. 7th, it was resolved, by a large majority, that the society should remain, as hitherto, a separate and independent one. Accordingly no further steps will be taken with regard to the suggested incorporation with the Royal Society of Medicine.

MANCHESTER ROYAL INFIRMARY.—The second series of the Ellis Llwyd Jones post-graduate demonstrations on Diseases of the Ear will be given at the Manchester Royal Infirmary on Fridays at 4.30 P.M. this session, starting on Jan. 30th. These lectures were founded by Sir James E. Jones, of Rochdale, and three courses of ten practical demonstrations, at which the number of postgraduates attending is limited to 12, are given every year by a member of the aural staff of the infirmary. The first course was given by Sir William Milligan and the present series will be given by Mr. Lindley Sewell, assistant surgical officer to the aural department. Further information may be obtained on application to the general superintendent and secretary, Manchester Royal Infirmary.

Reviews and Notices of Books.

VENEREAL DISEASE: ITS PREVENTION, SYMPTOMS, AND TREATMENT.

By HUGH WANSEY BAYLY, *M.C.* London: J. and A. Churchill. 1919. Pp. 152. 10*s.* 6*d.*

IT is natural that in correlation with the great attention directed to venereal disease within the last few years there should be a large output of manuals treating of this branch of medicine. The time has now come when any addition to the number of works already published on the subject must be justified by some strong claim to originality. Mr. Wansey Bayly's book satisfies this condition. The author brings out in a style which is all his own the importance which attaches to the measures for dealing with venereal diseases from a sociological point of view. If it has no other result, his useful manual will bring home to medical men the great influence which it is in their power to exert in other ways than by the actual treatment of disease. The public at large looks to the medical profession for guidance on the manifold sociological problems associated with venereal disease. It is the plain duty of every practitioner to acquaint himself with the fundamental factors involved in those problems. Mr. Bayly offers to be his guide.

In the clinical portion of his work we think that the author would have been of greater service to the general practitioner had he dealt with his subject-matter in greater fullness. In the section on syphilis we miss any reference to the differential diagnosis of the primary chancre and the various kinds of rash. There is a slip on p. 18, where it is implied that the inguinal glands drain the testicles. We also regret the omission of instruction in the intravenous administration of arsenical preparations by the gravity method. We consider it can hardly be wise to encourage the practitioner to use the syringe until he has had very considerable experience under supervision, which should include an apprenticeship to the administration of dilute solutions by gravity. The account of gonorrhœa would be easier to follow and more helpful to the reader had the author devoted separate sections to the discussion of the disease in male and female. More space might well have been given to the subject of gonorrhœa in women. Nor can the account of the treatment of strictures be regarded as anything but scanty quantitatively and qualitatively.

But having said this by way of suggestion for emendation in future editions, we are confident that the book as it stands will prove both stimulating and useful to practitioners. The student will welcome the book as a crisp and well-arranged summary from which a concise knowledge may be gained of a subject which is not a compulsory part of the medical curriculum. The bold black-and-white sketches are, with the exception of Fig. 1, distinctly elucidatory.

CEREBRO-SPINAL FLUID IN HEALTH AND IN DISEASE.

By ABRAHAM LEVINSON, B.S., M.D., Associate in Pediatrics, Northwestern University Medical School, Chicago, &c. London: Henry Kimpton. 1919. With 56 illustrations, including five colour plates. Pp. 232. 16*s.*

DIE LUMBALPUNKTION.

By Dr. KARL ESKUCHEN, München-Schwabing. Berlin: Urban and Schwarzenberg. 1919. With 21 illustrations and 2 coloured plates. Pp. 188. M. 8.

Dr. Levinson's monograph constitutes a useful and practical compendium of knowledge in all that pertains to the cerebro-spinal fluid. Its subject-matter deals with the anatomy and physiology of normal fluid, its physical, physicochemical, and biochemical properties, with the changes that take place in it in disease, methods of examination, modifications in specific diseases, and intraspinal treatment of various kinds. The book is well illustrated and printed. Its chief merit is the evidence it reveals of first-hand practical knowledge on the part of the author, as anyone familiar with the subject soon gathers. Perhaps one of its defects is the too succinct description of the cytology; plasma cells, e.g., are not mentioned apparently, nor macrophages (Gitterzellen). A compendium of this sort will be very valuable both to the worker in the clinical laboratory and to the physician interested in the scientific side of medicine.

Dr. Eskuchen's treatise on the cerebro-spinal fluid well illustrates the immense advances in knowledge since the days of Quincke, some 180 closely printed pages being packed full of information. Special attention may be directed to the excellent summary of the fluid findings in individual nervous and other diseases, to which some 45 pages are devoted. Valuable as this summary is, it is incomplete without a reference to encephalitis lethargica. The Lange gold reaction receives that full notice which its increasing importance in neurology demands. One of the most interesting sections is on the fluid content in tumour cases and on the differential diagnosis of spinal from intracranial tumours by fluid tests. This monograph can be confidently recommended to all who would keep themselves abreast of the subject.

THE END OF A DREAM.

By A. M. N. JENKIN. London: John Lane. 1919. Pp. 292. 7*s.*

THE novel of "shell shock" was bound to come. Shell shock is too convenient a cliché to be overlooked, devoid though it is of any specific meaning. The author of "The End of a Dream," not content with having his shell-shocked hero commit double murder and suicide, piles Pelion on Ossa by making him a morphinist also. It is regrettable that a whole series of horrors should be attributed to shell shock so-called. If the author knows so much he should in fairness have gone further, and explained to his readers that shell shock itself in no way accounts for the unconscious trends and impulses of the potential criminal. In so far as the book may realise his hope of constituting a plea for sympathetic consideration of the mental wounds of war it may possibly justify its publication.

JOURNALS.

Journal of Hygiene. Vol. XVIII., No. 3, October, 1919.—This number contains articles dealing with a wide range of subjects, as the following brief abstracts indicate. J. Burton Cleland and Burton Bradley, Experiments in the Etiology of Dengue Fever. With clinical notes by W. MacDonald. In continuation of work on this subject the authors find that dengue fever may be transmitted to a healthy non-immune man by the injection of blood taken from a patient on the second or third day of the disease. The incubation period of "artificial" dengue fever is from six to nine days. The virus is not kept back by a Pasteur-Chamberland F filter, and "is resistant to conditions outside the body for several days." Four "generations" of artificial cases of the disease have been obtained, failure to obtain more being due to lack of volunteers. Dengue fever is transmitted naturally in Australia by the yellow fever mosquito, *Stegomyia fasciata*. It has not been possible to transmit the disease to guinea-pigs or rabbits.—Two instances of Human Sera showing Abnormal Anti-Complementary Power, by E. L. Kennaway and Captain A. M. Wright. This condition is of practical importance, since it might lead to errors of diagnosis by the Wassermann reaction. In the cases described the amount of complement fixed by the serum in one case was about six times the normal and in the second four times.—Captain J. W. McLeod, R.A.M.C., gives an account of his experience in the use of brilliant green in the isolation of typhoid and paratyphoid bacilli from stools. His conclusions are favourable to the method.—In a paper on the Bacterial Content of the Air in Army Sleeping Huts A. J. Eagleton shows that in the ordinary infantry sleeping hut there is a stagnant well of infected air extending up to eight feet from the ground level, in which the men sleep. It is proved how readily the meningococcus can spread from a carrier to a susceptible man. The practical conclusion is that better, and preferably ground, ventilation is needed. —An Experimental Investigation of an Australian Epidemic of Acute Encephalo-Myelitis, by J. Burton Cleland and A. W. Campbell. This is an investigation of an epidemic disease which was prevalent in New South Wales in the late summer of the years 1917 and 1918. It was very fatal (94 deaths out of 134 cases), and was confined to districts remote from one another and from Sydney. The disease is communicable to the monkey, the sheep, horse, and calf. Clinical features included convulsions, rigidity, increased reflex activity, mental confusion, and pyrexia; paralysis seldom occurred. The virus was not obtained.—On the Effects of Injections of Quinine into the Tissues of Man and Animals, by L. S. Dudgeon. A concentrated solution of quinine is rapidly absorbed from the tissues. The lesions caused by such solutions are described and figured.—Studies on the Action of Electrolytes on Bacteria, by C. Shearer.

British Journal of Ophthalmology. May–December, 1919.—In the May and June numbers two interesting papers appear bearing on the functions of the pituitary body. They were both read before the Ophthalmological Section of the Royal Society of Medicine.——In the May number James Taylor publishes skiagrams showing enlargement of the sella turcica in two cases of Leber's optic atrophy, supporting a theory of the disease which had previously been propounded by Herbert Fisher. ——In the June number Herbert Fisher himself puts forward a theory of migraine, namely, that it is the result of a temporary swelling accompanying overactivity of the pituitary body. In such a case no bone changes are to be expected.——In the July number Priestley Smith discusses tenometric values in relation to the Schiotz and McClean tonometers, Ernest Thomson contributes some statistics of myopia in school children, and H. R. Jeremy records an interesting case of cataract following thyroidectomy. No previous case of the sort has made appearance in the English literature, although two cases have been described in Germany, and an experimental case of the sort in a dog was recorded by Walter Edmunds in 1916.——In the August number Charles Maghy sets out a case of Bilaterial Glioma of the Retina, from the Moorfields laboratory, in which the second eye was excised at the age of 20, 18 years after excision of the first eye.—In the August and September numbers there is a survey of 1201 cases of concomitant squint occurring in the practice of the late Mr. P. W. Maxwell, of Dublin. —In the same numbers a somewhat abstruse paper, by E. M. Eaton, appears, read before the Royal Society of Medicine, on the Visual Perception of Solid Form. The theory of corresponding points on the two retinæ to explain binocular vision is tried and found wanting. The alternative explanation favoured is a psychic rather than a physiological one. "The perceptive axis of vision lies between the fixation point and the middle of the interocular space. Its use involves a psychic modification of all visual angles similar to that which enables us to interpret foreshortened images in accordance with their true values. The perception of position in three dimensions is a function of the sense of directional projection of the two eyes." "The binocular element in vision contributes a valuable quota to stereoscopic perception, but it is one of many factors. The relative part of each factor varies with the type of view, and no individual factor is universally essential." The sentences quoted represent the most striking conclusions. The arguments by which they are supported must be studied in the original paper.——In the October number J. Gray Clegg discusses the notation of the axes of cylinders and the various systems in use in this and other countries, in the hope that uniformity in this matter may be attained.—In the same number J. A. Wilson give details of five cases of gunshot injuries of the cortical visual areas.——November: A. F. MacCallan: Causes of Non-trachomatous Ophthalmia in Egypt. For some years this observer has been publishing papers displaying the connexion between the rise of temperature in the summer months and the incidence of different forms of conjunctival infection. There always is a very marked increase of cases during the summer months, in which increase the gonococcus plays the chief part. Taking the gonococcal cases by themselves, their increase is found to follow the spring rise in temperature, not reaching the maximum until October. Conjunctivitis due to the Weeks bacillus, on the other hand, shows its maximum incidence in the months of April and May. Conjunctivitis due to the Morax bacillus is comparatively evenly distributed through the year.—Sydney Stephenson: Eye Symptoms as the Only Indication of Fractured Base of the Skull. Cases in point are detailed showing one or more of the following symptoms: subconjunctival ecchymosis, retinal hæmorrhages, paresis of one external rectus, and optic atrophy.——December: G. M. van Duyse, jun., from the Ophthalmological Laboratory of Ghent, contributes a paper on the pathology of colobomatous and microphthalmic eyes.—A. S. Percival relates two cases of diplopia after violence which he diagnosed as injury to the trochlea of the superior oblique muscle. The report is given in full of the Council of British Ophthalmologists on the desirability of a special qualification in ophthalmology.

Quarterly Journal of Microscopical Science. Edited by Sir E. RAY LANKESTER, with the coöperation of Professors HICKSON, BOURNE, GRAHAM-KERR, and MACBRIDE. Vol. LXIII., Part 4, and Vol. LXIV., Part 1. London: J. and A. Churchill. 1919. 10*s.* 6*d.* per part.—*Journal of the Royal Microscopical Society.* Edited by C. SINGER, assisted by Professor THOMSON, Messrs. DISNEY, RENDLE, and BROOKS. 1919. Part 1. 10*s.*—These two numbers of the *Quarterly Journal* contain between them 13 communications upon very various zoological matters, including technique, and one review; of these only a few can be selected for notice here. Professor Gilbert Bourne sketches, in an article entitled "Fifty Years of the *Quarterly Journal of Microscopical Science* under the editorship of Sir E. Ray Lankester," the immense progress of zoological science accomplished in that period as illustrated by the work published. The names of the authors mentioned include by far the greater number of prominent zoologists of to-day and the immediate past. Almost the only conspicuous name omitted which we have noticed is that of Professor Bourne himself.—A highly interesting paper by Mr. Bahl, of the Allahabad College, contains a renewed investigation, under favourable conditions, of the nephridia of certain Indian earthworms belonging to several species of the genus *Pheretima*. A new fact of importance is the discovery of abundant openings of the excretory tubes into the gut, thus throwing doubt upon (as Professor Woodland observes in a footnote), or at least demanding a reconsideration of, the view held by many that these organs are purely ectodermic in origin. Mr. Bahl also asserts that the multiple nephridia of the *Pheretimas* are isolated, and that there is no connexion between those of one segment and the antecedent and succeeding segments. He does not, however, as we understand him, do more than assert this generalisation for the species with which he was actually concerned. —In an article On the Terminology of Parthenogenesis the editor usefully reviews and corrects existing phrases in vogue among biologists for the various phenomena of asexual reproduction. For instance, the production of a tadpole from an unfertilised egg which has been stimulated to development by the scratch of a needle, or the "broods of greenfly produced without the intervention of a male parent" have been spoken of as "parthenogenesis." It is impossible, as Sir Ray Lankester says, to use the same term for the condition of the mother and that of her offspring. Such cases are best termed "impaternate." Minute cytological work is shown in Mr. Goodrich's paper on the pseudopodia of invertebrate leucocytes, which are not, he shows reasons for thinking, actual, more or less rod-like, mobile, outgrowths, but the optical expression of folds upon an extremely delicate membrane.——The issue also contains the Presidential address by Mr. J. E. Barnard, a technical memoir upon eye-pieces, and the usual abstracts, so useful to zoologists and botanists, of current literature on those sciences.

THE LANCET.

LONDON: SATURDAY, JANUARY 24, 1920.

The Insurance Practice Settlement.

AFTER strenuous exertion on both sides a settlement was reached late on Wednesday evening, Jan. 14th, between the representatives of the Ministry of Health responsible for administering the Insurance Acts and the representatives of the practitioners who provide the medical benefit, and a letter embodying the terms of this settlement reached the secretary of the Insurance Acts Committee of the British Medical Association in time for insertion in the supplement to last week's *British Medical Journal.* It is now generally known that the increased capitation fee of 11*s*., offered by the Government in place of the 13*s*. 6*d*. claimed by the Conference of Panel Committees, was at first refused by the Insurance Acts Committee, and then, in accordance with the discretion given to the Committee at the Panel Conference, referred to arbitration. The reference to the arbitrators, who will, we understand, include a medical man, an actuary, and a lawyer, will be to advise the Government what capitation rate will afford to insurance practitioners fair remuneration for the services required under the new Medical Benefit Regulations for 1920. The arbitration is to be confined to this single issue, it is to be completed within four weeks, and the award is to be binding upon both sides. On the part of the practitioners the condition is attached that panel committees will do all in their power to secure a full and efficient medical service, with good will, under the settlement as a whole.

Whatever the award may be, and it is important in the interests both of the insured population and the medical service that this should approach the figure desired by the medical profession, it will have the element of immediate finality. The capitation basis of 11*s*. comes into force as from Jan. 1st, the basis as settled by arbitration on April 1st, and it is part of the pledge given by the Insurance Acts Committee, on behalf of insurance practitioners, that their work will be done with good will on this financial basis. It was obviously necessary to fix some basis to enable both parties in a huge coöperative concern to carry on during a transitional period. But the settlement also contains the element of future flexibility. The Government has elected not to enter upon any arrangement binding for a term of years, but, in view of further legislation affecting the whole working of the Insurance Acts, to leave open the path to readjustment after consultation with the representatives of panel practice. Changes, as they become inevitable, will be made step by step after mutual counsel between the contracting parties, and with the increasing confidence of honest intention which is always the result of familiar intercourse. The ground is now being laid for a more informed, and therefore a fairer and easier readjustment, when the time comes to discuss again the basis of remuneration.

Another aspect of the conversations between the Ministry and the Insurance Acts Committee is of equal or greater importance. In most cases, it is stated, the Ministry met the desires of the Panel Conference, and the new Regulations which come into force on April 1st represent a very large amount of give and take. Only in regard to the clause dealing with the transfer of practices is the concession obtained less than had been hoped for. But here, it is to be remembered, the Regulations allow a large liberty in administration, and as the clause now stands the possibility is not excluded of Insurance Committee and Panel Committtee arranging for the allocation of patients in a manner best adapted to local needs, with proper consideration both for the rights of the patient and of the doctor. No one who looks beyond the conditions of present-day insurance practice into the future possibilities of prevention of disease can postulate the goodwill of a practice as an unalterable and inalienable attribute. Wise foresight suggests the adoption of some pension scheme which should gradually free the practitioner from dependence upon his patients as goods and chattels. Relief from carking anxiety, a main object of the Insurance Acts, is just as desirable for the practitioner as for the insured person.

◆

Diverticulitis.

DIVERTICULITIS is a comparatively new disease, if we hold that a disease is born by being given a name. The first classification of cases of the disease was made in 1908 by Dr. W. H. MAXWELL TELLING, who opened the recent discussion on the subject before the Proctological Subsection of the Royal Society of Medicine, and since 1908 the condition has received more and more notice, until at the present time its importance and its frequency are being fully recognised. The condition, unnamed, was identified as far back as 1885 by Sir ARBUTHNOT LANE. By the term diverticulum is meant a pathological sacculation proceeding from some portion of the large intestine, and chiefly seen in relation with the sigmoid flexure. The walls of these diverticula are formed not by all the coats of the bowel, for the muscular coat is wanting. As to their ætiology there is nearly general agreement that they must be explained as caused by some form of increased pressure within the bowel, but there is evidence that this is not the whole truth, for in some cases many are present and in others they are few in number. In some there seems to be a special weakness of the involuntary muscle fibres of the body, for cases have been described in which diverticula of the bladder were found to co-exist with diverticula of the colon. By certain writers stress has been laid on venous congestion as a cause of the existence of diverticula, but in a series of bodies examined by Mr. HAMILTON DRUMMOND, many of them were those of elderly people with chronic heart disease and marked back pressure, yet in none were diverticula found. Evidence of intestinal obstruction was present in only 10 per cent. of the cases of diverticulitis, but this does not preclude the possibility of increased pressure within the bowel in the other cases. LANE, in a paper written for the Guy's Hospital Reports, and quoted from elsewhere in this issue of THE LANCET, described a case of multiple diverticula from the colon, and expressed the opinion that the two factors in the production of the saccules were the action of tension and the presence of fat. The suggestion that these diverticula are congenital in origin was put forward before the Subsection by Mr. G. GREY TURNER, but this idea did not find favour with Mr. ERNEST MILES, who regarded an increase in the intracolic pressure as the essential cause. It will be best at present to confess that we have no certain knowledge of the mode of production of these protrusions, but, as they have been described almost exclusively in those over middle life, the probability of their being truly congenital in origin is but small.

Except to those who have devoted special attention to the large bowel the structure of diverticula may be unknown. For the most part they are small and almost invisible from the exterior of the bowel; and even when the mucous membrane is examined the apertures may easily escape notice unless search is specially made for them. These openings are often very small; they may be as minute as a sixteenth of an inch in diameter; rarely do they exceed a third of an inch, and often they are completely concealed by the rugous mucous membrane. As the diverticula pass outwards they may enter the appendices epiploicæ, and they are then entirely invisible from the exterior. So long as a diverticulum is not inflamed no harm seems to follow its existence, but, as in the case of the vermiform appendix, when fæcal matter collects within it, inflammation is very liable to arise, and from that inflammation several results may follow. The simplest is the formation of adhesions to the surrounding structures, but it is seldom that the consequences are limited to this. The fæcal contents form a reservoir of bacteria and their toxins. The mucous membrane of the diverticulum ulcerates, and this may lead to perforation with extravasation of the contents into the peritoneal cavity, with all the symptoms and results of peritonitis, or the adhesions which have previously formed may prevent the more serious consequences of perforation. If the diverticulum has become adherent to a hollow viscus a fistulous communication will be established between the colon and the other viscus, and in this way may arise colo-vesical or colo-vaginal fistulæ. Again, inflammation of a diverticulum may result in an extensive infiltration of the tissues around the colon with the formation of many adhesions, so that a mass is formed, and to this condition the name of peridiverticular fibrous hyperplasia has been given; this oftentimes leads to narrowing of the gut, with more or less obstruction. Many of these cases have been mistaken, and excusably mistaken, for instances of carcinoma of the bowel, and have been treated by colostomy or colectomy, as appeared best. Peridiverticulitis forms a solid mass in the wall of the bowel with obvious narrowing of the lumen, and the diagnosis between it and malignant disease may be very difficult indeed. Here the X rays may afford assistance. Dr. IVENS SPRIGGS at the recent debate showed that even small diverticula no larger than a currant could be clearly recognised on an X ray plate; but the diverticula which admitted the barium meal were permeable and probably healthy. The presence of healthy diverticula is suggestive of others which may be inflamed, and therefore the X ray plate may be helpful.

The treatment was summed up by Mr. R. P. ROWLANDS in the course of the debate, when he urged that every surgeon, in operating for obstruction of the colon, should keep in mind the possible presence of diverticulitis. Early resection of the whole of the affected portion of the colon with end-to-end anastomosis is the operation of choice, but in late or complicated cases temporary colostomy may be advisable. Sometimes, indeed, it may be desirable to make a short circuit, leaving the resection for a subsequent operation, but this procedure can be required only in late and serious cases. As Sir JOHN BLAND-SUTTON well said, the most important point about diverticulitis is its mimicry of cancer of the colon. Of the many cases that have been recorded of the spontaneous disappearance of an abdominal tumour some were doubtless instances of diverticulitis; there are patients who have refused operation for what they were assured by physicians and surgeons of great repute was cancer of the colon, and yet have recovered to the surprise of their medical advisers. It must never be forgotten that an apparent carcinoma, causing chronic obstruction of the large bowel, may be after all diverticulitis, demanding similar treatment, but with a vastly better prognosis. The discussion at the Royal Society of Medicine has been a valuable one. Many to whom diverticulitis was little more than a name will in future have clear ideas of its nature and be on the look-out for its appearance.

◆

Medical Education and the Poor-law Infirmaries.

SIGNS are not wanting of a new attitude on the part of the public towards medical education. This, they begin to see, is no longer the affair of the schools of medicine only; it has become a matter of public interest. That new standpoint is a legacy of the war, the natural outcome of public interest in recruiting and in pensioning boards, and more generally in the work and methods of the profession in war-time. The General Medical Council, the State authority upon medical education, has long seen and anxiously discussed the problems ahead, and it is conceivable that in the wider diffusion of experience that now exists some of the difficulties will disappear. The new agreement between St. Mary's Hospital and the Paddington Board of Guardians, by which the clinical material of the Paddington Infirmary will become available for the instruction of the medical students of St. Mary's Hospital, is an excellent example of recognition by the public of scientific needs. The idea is not new, but now that it has been put into practice it should follow that other medical schools will seek to make similar arrangements, when the departure will be seen to constitute a considerable event in the history of medical education and in the life of the Poor-law infirmaries. During the war the Paddington Infirmary was used as a military hospital. When it reopens in February there will be no workhouse, and the infirmary will provide accommodation for 600 beds.

The possibilities of undergraduate instruction in infirmaries are not generally appreciated. In 1913 some 25 per cent. of the total admissions to the Paddington Infirmary were under ten years of age, and in the same year more than half the cases remained in the infirmary for less than one month, over three-quarters for less than two months, and less than 5 per cent. for more than six months. There is therefore no foundation for the widely prevalent view that the wards of these institutions are filled with chronic and incurable disease in aged subjects. The infirmary, in fact, contains about equal numbers of two types of case. In the first group, the nature of the patient's illness and its severity in no way differ from the clinical material in the wards of a general hospital; the majority of cases are children, or patients requiring surgical treatment. The second group is largely made up of a type and stage of disease that is not generally found in the wards of those hospitals, and provides valuable material for investigation and instruction in every form and phase of chronic illness, but especially in diseases of the respiratory tract and in chronic heart disease. In particular this is true of pulmonary tuberculosis. The out-patient department for that disease at a general hospital does not at present meet the need for undergraduate instruction; accommodation in the wards for cases in both the early and late phases of the malady is necessary, but it is not provided, or is insufficiently provided. This the infirmary supplies. The cases received there fall into two groups: firstly, those which are detained pending arrangements for sanatorium treatment; secondly, those which are too advanced to profit by such a course, and which are kept indefinitely. Here indeed is fine material for medical instruction.

The surgical wards of the infirmary are enriched by the inability of general hospitals to take into their beds the number who require admission. Every year a considerable proportion of patients, whose names are added to the waiting list by the out-patient surgeons, have to be subsequently informed that there is no prospect of their being admitted to the hospital. Accordingly, in the compilation of the in-patient waiting list this shortage of beds is kept in mind, with the result that patients whose disease is not likely to be cured by a short stay in hospital are only added to the list with reluctance or for some particular scientific reason. The selection goes farther, for patients suffering from septic infections, such as cellulitis, are referred to the infirmary, and it has become necessary, in some general hospitals at least, practically to exclude all fractures from the wards except such as require an open surgical operation for their reduction. Hence a very large proportion of fractures of the lower limb are passed on to the infirmaries by these hospitals, and the modern student has less opportunity than his predecessors of becoming acquainted with the treatment of fractures. It has been possible for him in the past to go through his course only rarely seeing the treatment of such diseases as tuberculosis of the spine and hip, chronic septic osteomyelitis, the palliative treatment of malignant disease, and some acute inflammatory and orthopædic conditions. Further, a hitherto distinct hiatus in medical education should be filled by the provision of psychiatric clinics for incipient mental disease, while if these clinics are established in the infirmaries there is need for a recognised authority on psychiatry to direct the treatment, and for workers in pathology to take part in scientific investigation. In an agreement between a general hospital and an infirmary these needs should be met, and the student have an opportunity of seeing the early manifestations of mental disorder.

The arrangements between St. Mary's Hospital and the Paddington Infirmary will result in something more than an addition of 600 beds to those at St. Mary's. They will provide facilities for instruction and investigation which do not at present exist in general hospitals. It is probable, too, as the outcome of the provision of a wealth of clinical material, that out-patient teaching at the general hospital will devote itself more to the beginnings of disease, and to a type of case in which the malady is not sufficiently advanced to provide gross physical signs. When the student's preoccupation of mastering signs is safeguarded elsewhere, he will be encouraged to follow an illness throughout its course and to interpret the first warning symptoms in the light of subsequent events. The public gain directly by the conversion of a Poor-law infirmary into a modern hospital, equipped with the same resources as those of a general hospital, and, like it, able to enlist the services of a large staff. They gain indirectly in that greater facilities for becoming efficient are placed in the hands of those who in the future will become responsible for the health of the country; and it is in the recognition by the guardians of this indirect gain that the real significance of the change is to be found. While the cottage hospital exists for the care of the sick poor and for the provision of local benefits, the general hospital to which a teaching school is affiliated has a larger mission. A teaching school exists to set up a standard of efficiency throughout the country, to add to knowledge, and to secure the common good by sending out from its walls graduates fully equipped to take their part in the work of medicine, preventive as well as curative. The success of that work is brought a little nearer by the action of the Paddington Board of Guardians.

Annotations.

"Ne quid nimis."

UNSTABLE HYDROGEN PEROXIDE AND ITS STABLE SIMILARS.

THE announcement by the War Office in an Army Council Instruction issued recently that the supply of hydrogen peroxide to military hospitals will be limited to very special cases which cannot be treated satisfactorily by some other antiseptic will be viewed with dismay by those who have cause to appreciate the application of this cleansing and healing agent. We understand that this action has been taken in view of the unstable nature of hydrogen peroxide solution, the difficulty of obtaining and cost of suitable containers, the excessive loss by bursting and leakage, the great bulk of the liquid, and the high cost of transport. The virtue of peroxide of hydrogen in medical practice lies in its profuse oxygen content—a fact, of course, which gives rise to its instability. Were the compound stable, medicine would probably have a very limited use for it. But the extemporaneous preparation of hydrogen peroxide solution is by no means difficult, and we bring the suggestion forward to the notice of those who may suffer from a curtailment of supplies. It is well known that there are per-salts—as, for example, the per-borates and the per-carbonates—which readily yield available oxygen. All these are obtainable in the dry state, and therefore the drawbacks raised by the War Office as regards instability, loss of oxygen, difficulty of safe transport of hydrogen peroxide, do not obtain. As an example it may be quoted that 170 g. of sodium per-borate dissolved in a litre of water containing 60 g. of citric acid will give the equivalent of a litre of peroxide of hydrogen of "10-volume strength." The ingredients should be available in tablet form. Then there is per-carbonate of sodium, now made in commercial quantities, which can be similarly treated for the production of peroxide of hydrogen. It may indeed be an advantage to use these salts without the addition of an acid at all, for they practically present the oxidising power of peroxide of hydrogen in the presence, of course, of the alkaline salts respectively, borax and carbonate of soda. These points may be well worth considering where, though the need of peroxide of hydrogen may not be urgent, the active antiseptic and healing agency of its nascent oxygen is indicated or preferred.

THE NEED FOR ISOLATION HOSPITALS.

THE seasonal wave of the more common acute infectious diseases has by its unwonted volume drawn attention to the need for greater facilities for isolation. The daily press has brought embarrassing publicity to a number of highly respectable districts in the throes of scarlet fever, or diphtheria, or measles; while many others, probably no less implicated, have rejoiced to be able to blush unseen by the relentless eye of the reporter. This attention on the part of press and public, while rather fortuitous and undiscriminating in the choice of district to be pilloried, nevertheless serves a most useful purpose in awaking the communal conscience to the necessity for further means of isolation. For it must be recognised that although our cities and larger towns are second to none in the world in their provision of isolation hospitals, the small urban districts and a considerable proportion of the rural districts have notoriously failed to meet their responsibilities in this respect. Moreover, for two other, and very different, reasons there is some danger of a slackening of pace in the provision of isolation hospitals. In the first place, it was becoming somewhat of a fashion before the war to look coldly on the spread of isolation hospitals, to ask whether they were in fact a serious influence in diminishing the prevalence of infectious diseases, or whether they should not now be regarded as a not altogether necessary luxury in view of the decrease in virulence of most of the diseases with which they had happened to be concerned. In the second place, there has of late been a danger—perhaps as yet rather potential than actual—that the enthusiastic administrator of to-day, seeing that preventive medicine is now emerging from the lower plane of supervision of the environment to the higher one of care of the individual, may, in looking upwards, be oblivious of the many and huge gaps in that supervision.

The chief difficulty, however, is naturally that of the purse. Even before the war it was more than difficult for the average rural authority to provide its own isolation hospital. With the present enhanced prices it becomes almost impossible. From all points of view the intervention of the county council to exercise its powers of combining rural and the smaller urban authorities into hospital districts becomes the wise solution of the difficulty. Not only are the hospitals of a combined hospital district more likely to be economical in construction than the individual diminutive hospitals of separate authorities, but they can be better staffed and more efficiently managed, while the introduction of the motor ambulance has abolished one of the main difficulties in the practical utility of such hospitals for a wide area. Even under the Isolation Hospitals Acts of 1893 and 1901 county councils had wide powers in this respect, and could take action either on a petition by a district council or by 25 ratepayers, or on a report by the county medical officer of health. The procedure involved in the holding of an inquiry and the subsequent definition of a hospital district and formation of a hospital board was sluggish in the extreme. A stimulus to speedy action was given in 1913 by the Public Health (Prevention and Treatment of Disease) Act, which made provision for the recognition of county councils as local authorities for the purpose of erecting isolation hospitals. By obtaining an Order from the Ministry of Health, a county council can itself provide such hospitals and charge the cost to the districts concerned. It is now time that county councils should awake to a full sense of their increased powers and obligations. Their medical officers of health should be directed to report on the existing isolation hospital accommodation in the area, as a preliminary to a scheme for provision which shall at last be adequate for the needs of the community.

AN IMMUNITY REACTION.

THE Schick test for susceptibility to diphtheria has so far not received the same attention in this country as in America, or as its value would seem to warrant. Like the von Pirquet reaction in tuberculosis and the Calmette ophthalmic reaction in typhoid, the Schick test depends upon the presence or absence of specific antibodies in the blood, though according to Dr. H. Mason Leete's suggestive paper, which we publish in this issue, it is much more reliable than either of the former tests in practice. Dr. Leete's experience of the Schick test was obtained in the wards of the Edinburgh Fever Hospital, where he made an extended trial of its reliability as an indicator of diphtheria susceptibility, the results of which he embodies in his article, together with detailed instructions as to the necessary technique. According to Dr. Leete, with due care in its application, one important factor in which is the use of a reliable, carefully standardised toxin, the error in experienced hands is only 1 or 2 per cent., a pronouncement which constitutes a high tribute to its efficacy. As a test for the presence of diphtheria antitoxin in the blood in the case of persons who have been passively immunised against the disease, its value is amply confirmed by Dr. Leete's experience. Whether, however, as Dr. Leete believes, the reaction can be regarded as an equally trustworthy indication of the presence or absence of natural antitoxin and consequent immunity, or the reverse, is not so certain. The question is one not easy of settlement, since the crucial test—viz., the experiment of artificially imparting the disease in cases previously tested—is inadmissible in the case of human subjects, and to arrive at a conclusion of any value on this point under normal conditions would call for observations extending over a very long series of cases. As far as they go, the cases cited by Dr. Leete of patients who took diphtheria in hospital, and whose reactions had previously been noted, support his contention. In 10 out of 11 scarlet fever patients who contracted diphtheria the Schick test had been positive; in one the test was doubtful. He also quotes the fact that in two young children, who did not contract the disease although they had been in contact with diphtheria, the Schick reaction was negative. This experience, though confirmatory so far as it goes, can hardly be regarded as very convincing.

That different persons should evince varying degrees of susceptibility to infectious disease is interesting in itself, but the fact has a very important bearing on the administration of our isolation hospitals. This is particularly true of diphtheria by reason of its proneness to affect young children, especially such as are suffering or convalescent from recent inflammation of the faucial and naso-respiratory mucous membranes, as is the case in scarlet fever and measles. Any test of susceptibility to diphtheria which is at once reliable and easy of application should prove of the greatest service in hospitals largely devoted to the treatment of children. Not only would it enable measures to be taken for the protection of the children themselves, but it would also provide for the safety of the nurses and others attending on the diphtheria patients. The test should be most helpful in the allocation of both patients and staff, beyond which, in face of emergency, it would prove the deciding factor in giving prophylactic injections of serum in many cases, and, if thought fit, even in attempting an active immunisation in certain instances. Amongst the community at large the scope and utility of an immunity test like the Schick reaction would not appear to be anything like as great as in hospital practice, at any rate in this country. In America, however, where the diphtheria mortality reaches a higher figure than with us, the application of the Schick test is becoming more extended; indeed, we are informed that the New York Board of Health not only invite mothers to bring up their children to be tested, but even advise and undertake an active immunisation in positive cases.

TRANSFUSION OF BLOOD IN CIVIL PRACTICE.

ATTENTION has again been directed to the important subject of the transfusion of blood by an excellent summary of the literature of the subject which appeared in the December number of *Medical Science*. The extensive use of this means of resuscitation of badly wounded men during the war led to a temporary interest being taken in the subject and a considerable diffusion of knowledge of the methods, but it is possible that, with the end of the necessity for practising transfusion on a large scale may come a waning of interest, and that the knowledge may tend to remain restricted to those who practised it during the war. Another factor in the restriction of the knowledge and use of blood transfusion is the large claim that has been made for gum-arabic solution as a substitute for blood in the treatment of shock. This claim has not been fully admitted by many of those who have used gum on a large scale, but it is nevertheless widely believed that gum solution is "as good as blood" for purposes of resuscitation, and the comparative ease with which gum is administered helps to relegate blood, most undeservedly, to a secondary position. Urgent blood transfusion may not have to be done very frequently in civil practice, but it is nevertheless necessary that the theory and methods should be taught in the hospitals, so that house surgeons may be able to carry it out as an emergency procedure. The purpose of the summary in *Medical Science* is to draw attention to the uses of blood transfusion in civil practice, and it is evident from the papers summarised that the chief importance of the procedure in the future is likely to be its use as a therapeutic agent. It has been extensively used in America, notably at the Mayo Clinic, where 1036 transfusions were carried out between Jan. 1st, 1915, and Jan. 1st, 1918, the citrate method being used in the majority of the cases. The evidence as to the results is not yet complete, but there seems to be no doubt that considerable success has attended the therapeutic use of blood. The chief obstacle in the way of blood transfusion in this country is likely to be the provision of suitable blood donors. For therapeutic purposes a relative of the patient could probably be found willing to give blood, but in an emergency there might be some difficulty. The organisation of a hospital does not permit of the use of one of the staff of attendants as a donor, though in a teaching hospital a volunteer could probably be found among the students. Until there has arisen in England a new class of "professional blood donors," each hospital will have to make such independent arrangements as it thinks best.

THE NEW HOSPITAL FOR TROPICAL DISEASES IN LONDON.

IT is expected that the new hospital for tropical diseases, which is to be situated in Endsleigh-gardens, Euston-road, will be ready for patients this month. Roughly speaking, 58 to 60 beds will be available. One floor will be devoted to private patients, including cases from the India Office and Colonial Office, and for them small private single- or double-bedded rooms have been set aside. On another floor general cases will be dealt with, and here there will be two roomy wards, with a few single rooms in addition for special cases. The old tropical hospital at the Albert Docks, a branch of the Seamen's Hospital at Greenwich, is to be utilised as a source of supply for the new hospital, cases being transferred from there as required by ambulance. The physicians will be Dr. C. W. Daniels and Dr. George C. Low, both old superintendents of the London School of Tropical Medicine and both widely known for their researches and work on tropical medicine. As assistant physician Dr. P. Manson-Bahr has recently been appointed. Such a hospital should prove a great boon to a large class of sufferers from the tropics, because here they can be properly housed, have every attention, and, what is most important, be treated by expert consultant physicians with special knowledge of their diseases.

Running in connexion with the hospital will be the London School of Tropical Medicine under the care of Dr. H. B. Newham as director. Students will thus have the advantage of studying the cases at first hand and will also be trained in the scientific methods required for their diagnosis and treatment. It is expected that there will be a wealth of clinical material available and valuable research work will, we have no doubt, accrue from its study. The easy accessibility of the new building will be one of its chief assets.

ON PASSIVE MOVEMENTS.

IT appears that the majority of recommendations for treatment brought in from their local committees by pensioners are for treatment by "massage and passive movements." How futile would be treatment on these lines were it carried out is indicated by Mr. E. Stanley Brentnall in a brief but important note which we print on p. 198. Not everyone who is possessed of a limb that is not perfect can be benefited by massage or by passive movement. Dr. A. F. Hurst has emphasised the care which must be taken in all physical treatment lest we rub into a patient's mind the conviction of disability while we are trying to rub the disability out of his limb. It seems to be enough in some quarters for a patient to complain of pain or disability to ensure that he shall be recommended for treatment by massage. Valuable though physico-therapeutics have proved to be, they have their limitations, and the amount of time and energy that is expended in futile attempts to perform the impossible is, we fear, not inconsiderable at many clinics for pensioners. When a patient has been recommended by his local committee for treatment, before it commences he should be examined by a physician or surgeon competent to judge whether the treatment recommended is calculated to secure amelioration of the symptoms, and again by an expert in the treatment to be carried out, whose duty it would be to prescribe, in exact detail, the nature of the treatment. Medical referees attached to local war pension committees may not be qualified by experience in physical therapeutics either to prescribe the nature of treatment required by any individual or to judge whether the time has come that physical treatment can no longer be of benefit. Referees without special knowledge should order "treatment by massage for one month." The pensioner should be sent to a clinic for advice and, if necessary, for treatment. The case should then remain in the hands of the expert until he has done all that he can for his patient. Lack of definite instruction is responsible for the administration of much treatment by massage and passive movement which, if not entirely futile, is at best of only secondary importance as compared with active exercises and functional use, while the latter may be withheld if not specifically ordered. Treatment is thus unduly, it may be indefinitely, prolonged. Another point raised by Mr. Brentnall is the danger of passive movement. Of this, as a therapeutic measure, he has very little to say that is good, and much that is bad. Yet the disciples of Lucas-Championnière regard passive movement as an invaluable asset in treatment, and one devoid of danger if properly administered. This sharp divergence of opinion calls urgently for elucidation, for on the solution of the problem rests, in large measure, the whole question of manipulative technique.

SYNTHETIC ALCOHOL, AMMONIA, AND NITRATES.

SYNTHETIC methods are very much in evidence just now, and it is probable that great synthetic triumphs of the utmost importance to the industrial and economic world will be achieved at a quite early date. Only in August last we referred to the suggestions of the Inter-departmental Committee on the Production and Utilisation of Alcohol for Power and Traction Purposes. Those suggestions are evidently materialising, for the Department of Scientific and Industrial Research now announces the appointment of a Power Investigation Officer in accordance with the recommendations of the Inter-departmental Committee. The Fuel Research Board, acting under the Department of Scientific and Industrial Research, proposes to begin by bringing the work already being done, both as regards production and utilisation of alcohol, into proper focus. Sir Frederic Nathan, who has been appointed the Power Investigation Officer, was, before the war, superintendent of the Royal Gunpowder Factory at Waltham Abbey, and later works manager of Messrs. Nobel's explosive factory; he was subsequently appointed as officer in control of alcohol under the Ministry of Munitions during the war. He is now entrusted with the survey of the present position and with making proposals to the Fuel Research Board for such experiment and research as may from time to time appear to be necessary. The Department of Scientific and Industrial Research points out that it is obvious that until a more or less accurate estimate has been made of the possible sources for the production of alcohol within the empire, and until their probable amount and the cost of using them have been ascertained, it would be useless to embark upon research on any extended scale into methods of production or utilisation. The synthetic process of producing alcohol from ethylene extracted from coal-gas was described in an annotation in our issue of August 23rd, 1919.

It is well known that Germany adopted, from sheer necessity, a more or less successful process for the manufacture of nitric acid from the air. This process has been carefully investigated by English and French chemists, and last week a report was issued by the Nitrogen Products Committee (Cmd. 482), which recommends the adoption of the Haber process for the production of ammonia and the subsequent oxidation of this into nitric acid. The output might reach 10,000 tons of the acid, ultimately to be converted into nitrate for agricultural purposes. It was, however, announced in the *Times* of Jan. 17th that this process has been eclipsed by a new French process, the rights of which have been secured for the United Kingdom, South Africa, India, Australia, and New Zealand. Extensive works are to be erected in Cumberland, where there is a plentiful supply of good hydrogen-yielding coal providing the partner for the nitrogen of the air in the formation of ammonia gas (NH_3). By this process it is anticipated that no less than 50,000 tons of sulphate ammonia will be produced. What a remarkable confirmation is this of Sir William Crookes's striking prediction, in his memorable presidential address before the British Association for the Advancement of Science at Bristol in 1898, that sooner or later we should have to go to the air for our ammonia and nitrate supplies, and so maintain the food requirements of the world! It means, too, that the nitrates of Chili are no longer indispensable, besides which the supplies there are rapidly getting exhausted. It is to be hoped that these wonderful developments of synthetic methods will find their application in a world's peace, for nitrogen can obviously serve the activities either of ploughshare or sword.

THE ASSOCIATION OF SURGEONS OF GREAT BRITAIN AND IRELAND.

IN June, 1914, a meeting of surgeons of Great Britain and Ireland was held at the house of Sir Rickman Godlee in London to consider a suggestion made by Sir Berkeley Moynihan that an association of British surgeons should be formed. The principle was decided in the affirmative, but the outbreak of war put an end for the time to the taking of any practical measures. The opportunities of coöperation and mutual discussion afforded by army service encouraged the promoters of the association to further effort, and at a recent gathering at the Royal College of Surgeons of England, many surgeons being present from all parts of the country, Sir Rickman Godlee set forth the objects of such an association. He spoke of the need which had long been felt by surgeons in the British Isles for meetings at which they could learn each others' methods and discuss informally the many unsettled questions of surgery. In order that discussion might be free and frank it was proposed that no reporters should be present at the meetings, every member being left at liberty to publish his communications as and when he pleased. The *British Journal of Surgery* had been selected as the official organ of the Association. Annual meetings were to be held in different centres, those with medical schools being preferred. Sir George Makins mentioned the pleasure and instruction which he had derived from the provincial visits of the Surgical Section of the Royal Society of Medicine, and after he had spoken the draft of the rules was accepted by the meeting. The private character of the meetings, whatever drawback it may have in other respects, will allow of the presentation of tentative suggestions and the discussion of abuses. Members may enjoy the benefits of mutual criticism, while their ideas and methods are still plastic. Freedom of intercommunication makes for the advancement of science, and is a substantial guarantee against misunderstanding.

MEDICAL APPEAL BOARDS FOR OFFICERS.

MEDICAL Appeal Boards for officers, each consisting of a Deputy Commissioner of Medical Services, as chairman, an appropriate specialist, and a medical assessor, are being established at the regional headquarters of the Ministry of Pensions or at other convenient places within the respective regions. The Ministry announces that these Boards will hear all appeals based on dissatisfaction with the assessment of the degree of disablement. The Medical Appeal Board will also deal with claims based on deterioration of health since the last Board and made within one month of the date of the last Board, such claims being deemed to be based on dissatisfaction with the assessment. Claims in the latter category, made after a month, will be dealt with by special machinery which has been set up for the purpose. The Board will have before it all the relevant medical documents, including proceedings of the previous Board and any medical information which the appellant may furnish, so that it may be in a position to give an authoritative opinion. It will have power to raise, or lower, or confirm an assessment, and the decision will be binding for the currency of the previous award, provided that it will not preclude the review of the assessment during that period, if the officer claims that his condition has become substantially worse since the decision. Officers desiring to appeal or claim a reassessment must communicate direct with the Secretary, Officers' Branch, Ministry of Pensions, Chester Gate Huts, Regent's Park, N.W. 1.

CYSTIC URETHRITIS.

Dr. Maximilian Stern and Dr. I. Sidney Ritter,[1] of the Broad-street Hospital, New York, report the following apparently unique case. The patient was a man, aged 26, who had had gonorrhœal urethritis a year previously, and had been treated locally with solutions of argyrol, protargol, and potassium permanganate. As the discharge still persisted he was sent to hospital for diagnosis and treatment. When seen by the writers the patient had a slight watery urethral discharge, a smear of which showed a few pus cells but no diplococci. On cystoscopic examination the bladder was negative. Bullous lesions were seen just internal to the vesical sphincter. Throughout the posterior urethra there were grape-like clusters of cells, each having its individual blood-vessels. Numerous flat, irregular cysts were seen along the pendulous portion of the urethra up to the meatus, with an occasional small cluster of cysts resembling those found in the posterior urethra. The gelatinous contents of the cysts were easily expressed by the cystoscope, after which they presented the appearance of small tendrils, each with a red streak through its centre, indicating the presence of a distinct blood-vessel. The case was treated by fulguration three times at fortnightly intervals, together with instillations of 5 per cent. argyrol three times a week. Two weeks after the third fulguration no lesions could be found throughout the urethra.

THE LOCAL DISTRIBUTION OF MILK.

THE extension of the powers of local authorities to supply milk to children and to nursing mothers has been rapid. The latest step is the revocation of the Milk (Mothers and Children) Order, 1918, and the substitution of another Order which contains important provisions. Local authorities are now empowered to supply milk free or at less than cost price not merely in necessitous cases, but also where such a supply is deemed necessary because of the high retail price of milk in any area. While the Ministry of Health will supply the necessary funds under both conditions, the local authorities are reminded that a distinction must be made in their accounts between milk supplied to necessitous cases, under the Maternity and Child Welfare Act, 1918, and that supplied under the powers conferred on them by this new Order. The expression "milk" will be taken to include any preparation of milk prescribed by the medical officer of health or medical officer of a maternity and child-welfare centre, working in coöperation with the local authority. The addition of a maximum scale of quantity of milk to be ordered will be welcomed as an indication to prescribers. Children under 18 months may be ordered up to one and a half pints daily, between 18 months and 5 years one pint daily, while nursing and expectant mothers are left to the discretion of the medical officer certifying their need. Local authorities are urged by the Ministry of Health to extend their arrangements for the supply of milk under the Acts and to make known in their districts the local facilities provided.

A SUPPLEMENT [Cmd. 462. Price 1*s.* 3*d.*] has been issued to the forty-eighth (and last) annual report of the Local Government Board, containing the report of the medical department for the year 1918 with observations extending down to the end of June, 1919, when the Board ceased to exist. The supplement is mainly concerned with the records of certain infectious ailments, the progress of work for the prevention of venereal disease and tuberculosis, and that in connexion with maternity and child welfare, food inspection, and port sanitary administration.

A DRAFT scheme has been prepared by which the British Red Cross Society and Order of St. John of Jerusalem may be able to come to the immediate assistance of the voluntary hospitals, whose financial position, as a whole, has become critical. A conference will be held, under the auspices of the British Hospitals' Association, at St. Thomas's Hospital, to-day, Friday, Jan. 23rd, at 3 P.M., presided over by Mr. Wade Deacon, chairman of the Liverpool Royal Infirmary. Sir Arthur Stanley, chairman of the Joint War Committee of the Society and the Order, will submit the scheme, which is aimed at relieving the present difficulties of the hospitals.

MEDICAL PRACTICE IN BELGIUM DURING THE GERMAN INVASION.

(FROM OUR SPECIAL COMMISSIONER.)

I.

Dr. Pechère's statement to the Belgian Doctors' and Pharmacists' Relief Fund, published in THE LANCET of Dec. 20th last, justly evoked a profound and sympathetic emotion in this country, and represented, I know, the feelings of his countrymen. Much was said in but few words, and it was all well said; yet a great deal remains unrecorded, which your readers may like to learn from the personal experience which I have had an opportunity of obtaining.

The Story from Within.

Dr. Pechère explained the unavailing attempts that were made to send information over to England. The British subscribed to relieve distress, and the Belgians, in describing this distress, had to give details concerning the massacres of defenceless inhabitants, the pillaging and burning of villages. But the Germans did not intend to have their barbarous conduct thus exposed. They seized the correspondence, including the minutes of the Belgian Relief Committee (Comptes Rendus de l'Aide et Protection aux Médecins et Pharmaciens Sinistrés). Of course, before deciding what relief should be sent it was necessary to show why the relief was wanted. This is just what the Germans would not allow. The British doctors and pharmacists on their side, receiving no news, might have sent less help, but fortunately the British Belgian Doctors' and Pharmacists' Relief Fund, obtaining information from refugees, and having sympathetic foresight, took the responsibility of saying that all possible assistance *must* be wanted. And they trusted to fair distribution of anything that could be sent to Belgian organisers. Fortunately, after a while the Belgian doctors and pharmacists managed to get into touch with Mr. Hoover, who was rendering such magnificent service in organising the distribution of food sent from America. When Mr. Hoover heard what had occurred he contrived to forward information to England. The relief funds organised by the Belgians at the earliest moment for their suffering colleagues had been reduced to a very low ebb. At one moment there was not more than 10,000 francs available, whatever the emergency. When the British sympathisers at last heard from unimpeachable authority what was happening, the cheque of the Relief Fund came regularly to the Committee sitting in Brussels. The much-needed and great work of relief was successfully carried forward, at least whenever those who suffered could be reached. This was not always a simple matter. There was the German étappen or zone of communications and what was known as the fire region. There no correspondence whatsoever was allowed, no letters could be sent, no visits paid to the unfortunate inhabitants. To live near the fighting line or the road of the military services meant exile from all the rest of the world. Therefore, some of the relief in money was reserved for those whom it would only be possible to help at some unknown future time. This was a wise precaution, for since the evacuation of Belgium by the Germany army new and very distressful cases have been discovered.

The Terrors of Enemy Occupation.

Among the many victims there are the widows and families of the doctors and pharmacists who were brutally shot, of others who met an honourable death on the field of battle, and of others who died prematurely because of the awful strain and the insufficient food. In common with many of the outraged and oppressed inhabitants, medical men and pharmacists suffered from nervous tension. They were never safe. Anywhere, and at any time, day or night, they might be seized, or soldiers might enter their houses, ransack sitting and bedrooms, open cupboards, drawers, desks, and boxes. After having reduced everything in the house to a state of indescribable disorder they would go off, unfailingly with some rude parting jest. To show any resentment was to risk imprisonment, for on the slightest provocation the soldiers had the injunction to arrest whomsoever they pleased, and they, for the most part, executed their revolting work with alacrity. No papers and no property were safe. Much loss was experienced, not merely from actual destruction and pillage, but also because the searchers threw records and papers into hopeless disorder. This was notably the case at the town halls, municipal buildings, and administrative offices, but medical records of public and private work shared a similar ruthless fate.

The Work of Self-help in Belgium.

To help victimised members of the medical and pharmaceutical professions the Belgian doctors and pharmacists at the commencement of the war managed to raise at once some 50,000 francs amongst themselves. The medical clubs gave up all their funds, and this sum was augmented to 180,000 francs. The Belgian Ambassador at Rome received 25,000 francs from the Italian doctors, and the American doctors also sent some money. By a terrible tragedy much of this last relief was lost, for, as all remember with the deepest sympathy, the wife of Dr. Antoine Depage was drowned on the *Lusitania* when returning from America, where she had collected large sums on behalf of the Belgian Red Cross and medical services. But the total of money received, added to the British donations from doctors and pharmacists received through the Belgian Relief Fund—this last amounting in all to £27,000—supplied the means of giving help to 140 families of the two professions in their urgent need, while building up a reserve that has proved to be of the greatest value.

It is, however, very important to bear in mind that the money by itself could never have achieved so much had it not been for the admirable spirit of organisation prevailing throughout the Belgian medical and pharmaceutical profession. Speaking now of the medical profession, the Belgians have been among the first people in Europe in arriving at a system of organisation, and of this I may speak from personal knowledge. Under the heading of "The Battle of the Clubs," as far back as August 24th, 1895, I described, in these columns, how out of 450 medical practitioners established in Brussels 430 were paying members of the local Collège des Médecins, which is practically a medical syndicate of unions. Since then I have travelled all over Great Britain and many continental countries, describing the sort of organisations which medical practitioners have built up to defend and promote their professional and economic interests. The altered constitution of the British Medical Association and the National Insurance legislation, introducing panel practice, had as one of their common objects the removal of the abuses which I then described; but in those days, whenever I returned to Belgium, there was always some fresh and encouraging development, showing, to my mind, that the Belgians were more alert than the British in taking practical steps to help themselves and to realise professional unity. But to-day, after this terrible war, it was with much apprehension that I landed once more in Belgium. How could such a delicate organism as a professional union survive the shock of an invasion and long years of military occupation and oppression? The result has been just the contrary to what it was so natural to anticipate. No more emphatic vindication of the principle of professional coöperation could possibly be supplied than the fact that the Belgian Medical Union has not only survived the invasion, but, under this great strain and trial, has become stronger and more closely united than at any previous period.

Professional Union in Belgium.

Dr. Pechère, President of the Belgian National Relief Committee, Dr. Herman, President of the Belgian Medical Federation, and Dr. Antoine Depage, in welcoming me to Brussels, were able to explain joyfully that the war had drawn the medical profession closer together. The greater the difficulties of existence, the more the members of the profession had felt, and were feeling, the need of mutual support. Actually there were about 4000 medical practitioners in Belgium; more than 3600 were members, and good stalwart members, of the Belgian Medical Federation of Legally Recognised Professional Unions. (These were the figures given to me, and they show a smaller proportion considerably of medical men to population than prevails in England.) This does not mean an abstract recognition and approval of certain principles. It means the signing of a document that constitutes a legal bond. The statutes appeared officially in the *Moniteur Belge* of March 25th, 1911 (Act No. 182). Six articles define the objects of the Belgian Medical Federation, and the first article says that its purpose is to watch so that the principles of deontology which should govern medical practice are duly observed. Naturally this implies defence, mutual protection in moral and material questions; the exercise of influence upon the Government, so that the profession may harmonise with the Government. The second article deals with conciliation and arbitration in cases of disputes, and the third with the material interests of the profession. This latter stipulates for united action in negotiating with insurance societies and institutions such as benefit clubs, and the establishment of a minimum medical tariff. In a word, all the principal economic problems are involved.

When a question arises that is of sufficient importance, it can be submitted to all the unions, and what might be qualified as a national verdict is obtained. There are 40 medical unions, federated into one National Union, with headquarters at Brussels. Every local union can send a delegate to Brussels. If it has more than 50 members it can send two delegates, and three delegates if there are more than 100 members. According to law, dating from 1899, these societies have the right to buy and own property, and they may take any name they please. In this respect it is curious to note that the newer bodies adopt the word "syndicat." Therefore we have Le Syndicat Médical de Verviers, Le Syndicat Médical du Centre, &c., thus seeming to assimilate the claims of intellectual labour with the other forms of labour, and recognising the need of united action for the one as for the other. In any case, it was this spirit of organisation, of association, and of mutual support, taught and engendered before the war, that has enabled the Belgian medical profession to stand shoulder to shoulder and survive in spite of the war.

The Results of Extended Coöperation.

Only this faculty of organisation could have saved the previous situation. All the old landmarks were destroyed, the old customs could not be maintained, all the men of military age had disappeared, the factories and workshops were closed, some were destroyed, or the machinery they contained was carried away to Germany. Well-to-do clients found themselves penniless. In large towns many patients were able to continue paying their medical attendants, but in the country this was rarely possible. Therefore, what was done in former times for the poorer sections of the population had now to be extended to 600,000 families. Counting an average of four to a family, this meant two and a half million persons, or a third of the entire population of Belgium. For all these people the National Committee organised a system of medical and pharmaceutical help, but this would have been quite impossible had it not been for the assistance of the members of the medical unions. Nor would mere goodwill and a general desire to help have sufficed. A technical, practical experience of the working of what in England is often called the club system was necessary. Yet there was a great difference, a delicate complication needing much tact and kindly feeling. It was absolutely necessary to give help—money, food, clothes, just the minimum required to sustain life—to persons who had been in a good position, who were temporary war victims, and who, above all, should be spared needless social degradation.

The first principle set down was that each family, however poor, should keep their own doctor if he was still on the spot and willing to attend. The National Committee would give him not payment, but an indemnity; and this was done on the basis, at first, of 6 francs a year. In the course of time the allowance was raised to 9 francs, and is now 12 francs a year. This system of wholesale medical insurance proved a double blessing; it not only saved the patient, but in many cases it also saved the medical practitioner. As most men of the military age are just those who are best able to pay medical fees, the medical practitioner found that most of his paying patients had been compelled to fly on the approach of the invaders. But his position was saved when the National Committee paid him from 6 to 12 francs per annum for every family on his list.

(To be concluded.)

A STATE MEDICAL SERVICE:

A DEBATE BEFORE THE MARYLEBONE BRANCH OF THE BRITISH MEDICAL ASSOCIATION.

ON Jan. 16th, at the Rooms of the Medical Society of London, Chandos-street, W., at a meeting of the Marylebone branch of the British Medical Association, a discussion took place on the Future of the Medical Profession under a Salaried Whole-time State Medical Service. Dr. C. O. **HAWTHORNE**, who presided, said that such a discussion was appropriate to the day and hour, for circumstances had compelled the consideration, or rather the reconsideration, of the form and fashion in which the medical profession could best discharge its responsibilities as the director and promoter of public health. Some changes in this direction had already occurred, and other changes were on the horizon. One of the changes proposed by certain members of the profession who had given considerable attention and study to the issue was that no satisfactory position would be attained until the Government established a whole-time State Medical Service corresponding to other public services in the country.

Professor **BENJAMIN MOORE**, who opened the discussion in support of the formation of a State Medical Service, said that underlying the whole question was the advance which medical science and the medical profession had made in relation to the health of the country. If national medical service was going to be bureaucratically administered, the medical profession being the paid servants, he would have none of it. It was quite evident that some coördination would be brought into medical practice and concerted action was necessary to prevent the introduction of a lay bureaucracy. What he had in his mind was a system something on the lines of the old guilds, the management of which would be in the hands of the members of the profession. He drew a picture of the low standard of health among the working people generally, remarking that if the medical profession would get at it they must go forth and seek it. The public conscience had been more than merely aroused. The question of expense and of other matters in connexion with the coördination of a system could only be approached in a broad way, and the best way was by a salaried service. In order to attract the best brains in the country the service of the doctors must be as well paid as was the legal profession. The working of bureaucratic systems did not prove that nationalisation was wrong, because the country had not yet learned how to get the best out of such systems.

Sir **WILMOT HERRINGHAM**, opposing the idea of a State Medical Service, said that the scheme proposed was the dimmest that had ever been laid before any body of men on a serious subject. What had been said was that the profession must not wait for patients to come to it till they are ill, or think they are ill, but that the profession must go out to every house in the country to find out who are ill, and that the only way to do so was to have a salaried service, with, of course, £1000 a year. The Government would offer precisely the same pay as it did to other public services. To have to be continually working under an authority was a very strong argument against the proposal. Discipline such as prevailed in the army was not applicable to a progressive profession such as the medical. He thought that public service did, however much the people at the top might desire to prevent it, militate against improvements, against originality, and against enterprise. When Professor Moore said that he aimed at something which was not to be bureaucratic control, and that the whole thing must be taken into the hands of the profession, and that the first thing to be obtained was an agreement on the part of every medical man in the country to carry out a great scheme of this kind—then he said what all have asked for when they want some vast change in the medical profession. But they have failed to get coöperation. He did not think for one moment the medical profession would be able to get complete control of any State organisation. Health matters at the present time were regulated by the local health authorities, the doctors being an advisory body, and the managers lay people as they always would be. It was important to consider what ought to be done to improve the public health, but a scheme of this kind was not wanted and would not improve public health. Larger hospital accommodation was wanted, in some places especially, maternity accommodation, proper facilities for consultations, and better communication between the doctor who is looking after the case and the doctor who treats the case when in hospital. Also better pathological facilities were required, and here, as such service could not be paid by fees, there could be a whole-time service paid, and adequately, by the State.

Dr. B. F. **HARTZHORNE** said that under a State Medical Service the medical man who had gained a position by his own industry would lose his independence.

Dr. R. **FIELDING-OULD** said that when a man became a State servant he lost the psychical interest between himself and patient and became a machine.

Sir **WATSON CHEYNE**, M.P., said that with regard to prospective legislation he was looking at it from the State point of view as well as from that of the doctor, but so far he had heard no arguments to convince him that the community would benefit by a State Medical Service for treating patients, though it would have an advantage so far as sanitary service was concerned.

Dr. A. G. **AULD** said that while acting as tuberculosis officer he had seen lives lost owing to wrong diagnosis by panel doctors. The remedy was a house-to-house visitation, such as coincided with Professor Moore's recommendation.

Dr. **ALEXANDER BLACKHALL-MORISON** pointed out the good work that had been done in the past by collaboration among medical men before State legislation had been thought of, in illustration of which he pointed to the picture of the founders of the Medical Society of London which adorned the room.

Mr. C. A. **PARKER** questioned whether the system of private practice which had been going on for years had produced the best results. He did not believe the health of the country would be improved until we had a system under which everyone could get adequate medical relief, the middle class as well as the poor.

Dr. **BEDDOES** protested against the introduction of a bureaucratic system.

Professor **MOORE**, in his reply, referred his audience to details which were published by himself and others in THE LANCET about a year ago.[1]

Sir **WILMOT HERRINGHAM**, who also replied, said that while there was a great deal of disease in the country which the medical profession had not been able to stamp out, it did not follow that a whole-time State Medical Service would meet the case.

---

[1] THE LANCET, 1918, ii., 85.

THE LATE MR. E. F. H. BURROUGHS.—Ephraim Frederick Hastings Burroughs, L.R.C.S. Irel., L.A.H. Dub., died recently at his residence at Clifton, in his seventy-fourth year. The deceased, who was a member of an old Bristol family, had practised for many years in Clifton, where he was highly respected.

IMPERIAL WAR MUSEUM: THE NATION'S WAR PAINTINGS.

THE exhibition of war paintings now being held at the Royal Academy of Arts, Burlington House, is of the greatest interest, and we regret to learn that it will close at the end of this month. It follows that any who wish to take the advice we offer, and to see this remarkable collection, will have to act in the course of the next few days.

The exhibition includes the larger portion of the valuable collection of war pictures acquired, whether as gifts or purchases, by the authorities of the Imperial War Museum and by the Ministry of Information. A certain number of important paintings and drawings that have been secured for the nation, including a hundred by Sir William Orpen, are still in America. The collection of portraits, we learn, is by no means complete, and, as it is hoped to add considerably to the series in the future, we suggest that the medical profession counted for something in this war, and that there are at least six medical men, connected in the most distinguished manner with our undertakings on various fronts, whose portraits should certainly be included in any national record.

There is one reason why medical men should go to this exhibition themselves, and should urge the large public whom they influence to go there also—the pictures are perfectly frank: medical men, one of whose greatest difficulties it is to get down to essentials and to eliminate the unimportant, will appreciate the spirit. The work has been constructed from the bottom on the only foundation that can be solid: the fact that the artist's special view is not always the view which the spectator thinks should have been taken; the fact that one painter's accomplishment is indicated by exactly that precision which is wanting in the work of another; and, indeed, the fact that some of the exhibitors are better masters of their medium than others—none of these things have any bearing on the case. The pictures are evidence given by witnesses who desire to tell the truth. There are witnesses who bear better testimony than others, but there is no truthful witness who does not stand beyond comparison above him who palters with fact, refines with issues, or loses his essential points in intruding details.

In the first gallery two pictures (9 and 32), both by Sir William Orpen, depict mines at La Boisselle. It is not easy to guess the scale in these pictures, yet the medical significance of the second canvas (32) depends upon remembering that the interior of this "small mine" is about 80 yards across, so that the crevices depicted are proportionately deep, accounting for the long period during which the caverns were dangerous to life from contained gases. In this gallery note also Mr. Francis Dodd's "Interrogation" (29, referred to later) and Mr. C. R. W. Nevinson's convincing picture (39) "The Road from Arras to Bapaume." In Gallery II., Mr. Wilson Steer's "Dover Harbour, 1918" (54) has the accomplishment we should expect from a painter of international fame. It is an achievement that this apparently effortless piece of beauty should hold the eye in a room where more violent appeals are made. Here Mr. John Nash's "Deserted Trench" (48) brings the right feeling of horror. It is a strong large picture, painted small, and the drawing of the huddled bodies, which is sure, tells us that medical aid in these situations was seldom of use.

In Gallery III. is the picture which has been recognised by the public as the most important one in the whole collection, and we find in Mr. Sargent's "Gassed" (84) a perfect example of frankness. The episode is narrated without embellishment or concealment; it occurred on the Arras-Doulens road during the final advance of the Guards in August, 1918. The artist, learning that a large number of gassed cases were being brought to a Corps Dressing Station, drove there at once with a brother painter and actually saw the frieze of blinded men as he has depicted them, walking in single file, each with his hand on the shoulder of him in front, to receive attention for sudden blindness. The picture is bathed in a beautiful evening light, and its tragedy is heightened by the fact that Mr. Sargent put into the background, to be seen in the intervals of the suffering figures, a game of football which was actually proceeding close to the dressing station, among a merry group of soldiers. The great artist makes the great picture by telling the truth in splendid manner. There was such an evening, and the sufferers suffered, and the players played, just as they are depicted. Pathos is gained by the merriment, and the decorative beauty attained by pattern and by colour.

In the same gallery we find four other important pictures of medical interest, and they are among the finest achievements in the collection. Professor Henry Tonks has a beautiful canvas, "An Advanced Dressing Station in France" (77), in which the charming buildings and living figures make up a moving scene. The ruins of a town, dramatic in their simplicity, stand against a sky whose blue, flecked with white, is charged with heavy clouds behind the tallest fragments. The rest of the canvas is occupied with medical business. Note-taking and the application of tourniquets, the filing in, as in Mr. Sargent's picture, of the blinded, the bearing of stretchers, the reclining wounded have all given Mr. Tonks material for fine draughtsmanship and display of the technical knowledge which, as a F.R.C.S., he possesses. But neither drawing nor technique is obtruded; it is a whole picture, and a notable one.

The other pictures are by Mr. Stanley Spencer, Mr. Gilbert Spencer, and Mr. Henry Lamb. Of Mr. Stanley Spencer's "Travoys with Wounded at a Dressing Station in Macedonia" (75) the thing just said may be repeated; though crowded with incident it remains one picture. It is a vivid representation of mountain ambulance transport. The front of the picture is occupied by the backs of a row of mules, ascending the mountain abruptly with their burdens. On the plateau is a dressing station. With a license justified by the example of primitive Italians, Mr. G. Spencer, most modern of painters, has removed any structures that might impede our view of the scene, and the story culminates in a distant representation, quite faithful enough, of an operation in full swing. The sense of tug on the part of the animals, and of calm procedure in the station are perfectly rendered.

Mr. Gilbert Spencer's "Ward in a Stationary Hospital at Mount Sinai" (70). The realism is here easily intelligible. The study was made just previous to the first attack on Gaza in April, 1917, and represents the interior of a ward after a convoy has arrived. The patients, medical officer, sister, orderly, and necessary properties are set out so that we can understand the scene. But Mr. Lamb's surprising picture (80) of the effects of a Turkish bombardment upon a column of Irish troops in the Judæan Hills is less obvious. Mr. Lamb is an accomplished painter, who had formerly trained for the medical profession, who won the Military Cross for war services, and passed his medical examinations during the war. He has produced a picture which will delight those who can imagine, and will irritate those who only trust their own impressions without knowing the limitations of those impressions. The way in which the soldiers, surprised by the bombardment, are taking cover under the rocky terraces, is, we feel certain, correctly presented.

In Gallery IV., "Indian Wounded in the Dome at Brighton," by Mr. Douglas Fox-Pitt (112), is clever, and makes us feel that whoever selected the Brighton Pavilion for the shelter of Indian patients was clever also; the patients so fit their environment that the placidity which leads to recovery should have been secured. Medicine is little represented in this room, which contains a remarkable picture by Mr. C. J. Holmes, so well known as the Director of the National Gallery that we are apt to forget his rank as a painter. "A Two-Year-Old Steel Works" (102) is a big piece of work.

In Gallery V. one of Mr. Eric Kennington's canvasses "55 C.C.S., Q.5" (188) is a realistic picture of a casualty clearing station. It is in black and white, and the scene shows a group of patients, not severely ill or dangerously wounded, and many in the recovery stage. In this room we should note also from the anatomical point of view a picture by the same artist, entitled "Infantryman Resting" (225). The way in which the weight of the sitting man is distributed and his body supported by his gun is properly observed. We mention the fact because it is not unusual for the sitting presentments of accomplished artists to wear the appearance of sliding forward out of the frame. Observe in this room, also, the picture by Mr. W. P. Roberts, "An Attack" (228). This record of the capture of the Delville Wood gives a terrible idea of the country in the neighbourhood of the Passchendaele Ridge and of the sufferings of the wounded during the fighting in that area, when it took many hours at night to recover the injured on the battlefield. Alas! a great many in this region perished in the horrible morass. In Gallery VI. "The Doctor" (246), by C. R. W. Nevinson, deserves attention. It is strong, sombre, and rich. The inspection of a head dressing by a medical officer is the main episode, and the mask of suffering worn by the patient shows how near the tragic lies to the comic.

In Gallery VII. a large number of portraits by Mr. Francis Dodd, though not all equally pleasant, mark a high average level of accomplishment; it is in this series that we looked in vain for a protagonist of medicine. Here, also, the same painter has a fascinating picture of a submarine, while a Diesel engine is being repaired (282). The painting was executed while the vessel was submerged; the elaborate engineering work is indicated with force and economy of treatment, the men engaged being drawn with an effectiveness secured in the same concentrated manner. Mr. Dodd is a distinguished painter, for in Gallery I. we noticed a picture by him, "Interrogation" (29), which is one of the best in the collection. There are two British officers, a German prisoner, and a British soldier who brought the captive in. The four faces are a triumph of humorous observation. The intelligence officer is obviously pursuing a routine, but the general is keenly interested in what may be a critical disclosure. The prisoner is of high intellectual type, and aware of the grave issues involved in a situation which frankly amuses the sentry. While the story is thus made clear the picture as a whole is a beautiful and symmetrical thing. Nothing has been added in concession to any idea that it would help the spectator, and, because it is a great picture, nothing of the sort is missed.

This gallery contains also many striking works by Mr. Muirhead Bone, one of which we make bold to pick out for special mention—namely, "Panorama from the Scherpenberg" (311), a beautiful view purely done, and a workmanlike map exposing the conditions of the country. In Gallery VIII. Mr. Gordon's "Action Operating Theatre in a Battleship" (374) and "Burnt and Wounded in a Battleship after Action" (377) will remind us how very high was the percentage of the injuries in the navy due to burning and scorching accidents. In this gallery is a picture, "The St. Quentin Canal" (384), by Mr. Hughes-Stanton, which was painted from the temporary bridge erected across the canal towards Bellicourt. At this spot the canal was crossed by one of the North Midland Divisions of the 4th Army, with the help of rafts, mats, and lifebelts; they stormed the Hindenburg line, and an official dispatch states that so well was the attack executed that the one Division took on this day (Sept. 26th, 1918) over 4000 prisoners and 70 guns. The results of the exploit come out in the dispatch, but to understand its splendour one has only to look at this picture. How it was done physically can just be imagined, but the courage wanted must have been immense.

The medical interest in Gallery IX. is small, though the room includes "Saline Infusion" (429), an incident in a British Red Cross Hospital, by Professor Tonks, and a delightful "Interior of a Hospital Tent" (452), by Mr. Sargent. But the whole room is extremely beautiful, the water-colours by Mr. Sargent, Professor Tonks, Mr. W. Rothenstein, and others being quite delightful. "War Allotments in a London Suburb" (424), by Miss Dorothy Coke; "The Soloveski Monastery" (423), by Professor Tonks; the "Tarpaulin over a Dug-out" (455), by Mr. Sargent; "Via Dolorosa" (488), by Mr. Muirhead Bone may be mentioned, but other tastes will make other selections. Gallery X. is composed of Sir John Lavery's collection. All the pictures in the room were presented by the artist, who, however, was only moved to paint one medical picture, "Wounded at Dover, 1918" (513).

If we have drawn attention to some of the most important pictures from the medical point of view, there are many others with similar appeal that deserve inspection. Therefore we repeat the advice with which we began, and recommend our readers to visit Burlington House on one of the remaining days of the month.

SOME NOTES ON THE RECENT FRENCH CONGRESS OF SURGERY.

(FROM AN OCCASIONAL CORRESPONDENT.)

DURING the Twenty-eighth French Surgical Congress, of which a brief account appeared in THE LANCET of Oct. 18th, 1919 (p. 706), a daily series of operations was arranged, and some of the best French surgeons were seen at work. The list of operations was posted at the Secretariat in the Faculty of Medicine. This year among the surgeons operating were Victor Pauchet, T. De Martel, Pierre Duval, J. L. Faure the gynæcologist, Calot the orthopædic surgeon, Marion, Sebileau, and others representing different specialties.

I followed the work of the first three, and though these notes are belated in date I hope your readers will find them of interest.

Pauchet's Technique for Abdominal Operations.

Victor Pauchet performed over a dozen gastro-intestinal operations, besides others; these included gastro-enterostomies, jejunostomies, and gastrectomies for ulcer and cancer, colectomy, choledochotomy, and an excision of the rectum for cancer.

The following operations may be described:—

Gastrectomy for cancer.—Mesial incision and rapid examination of the tumour with regard to operability.

(1) Separation of the great omentum from the transverse colon by a few touches of the knife. This exsanguine proceeding gives immediate access to the posterior gastric wall and facilitates separation of the stomach from the pancreas. The stripping up of the great omentum exposes the pancreas, leaves behind the colic vessels in the mesocolon, and takes with it any glands below the pylorus, permitting easy ligature of the pancreatic duodenal artery as the dissection is prolonged well to the right over the duodenum.

(2) Freeing of the upper surface of the duodenum and pylorus and ligature of the pyloric artery. Crushing and section of the duodenum on a Mayo's clamp and invagination of the duodenal stump. The stomach is now swung over to the left, a Doyen valve lifts up the liver, and the coronary artery is ligatured as near its origin as possible.

(3) Clearing of the lesser curve. This important step is done by placing a Kocher's forceps half an inch below the coronary ligature. With a knife the arterial pedicle is cut near the forceps, the incision passing right down to the serous coat of the stomach. Traction being made on the forceps with the flat of the knife the tissues are scratched downwards, the lesser curve thus being cleared of its serous coat, vessels, and glands down to the site of section of the stomach three, four, or five fingers-breadth from the tumour.

(4) Placing of a crushing clamp (De Martel's or Mayo's) on the stomach well above the growth and removal by the cautery of the whole diseased area with the glands in each omentum attached to it.

(5) Closure of the crushed gastric stump by a continuous parallel suture over the clamp. Posterior or anterior gastro-enterostomy, the jejunal loop being brought up through the mesocolon and the anastomosis being fixed in the mesocolic opening.

W. J. Mayo once wrote that an operation by Tuffier for removal of an adherent kidney by subcapsular nephrectomy was in itself worth a visit to France. We felt the same might be said of Pauchet's gastrectomy for cancer. We saw him operate on several gastric cancers, and his rapid bloodless technique with its clearness of anatomical detail left the impression that gastrectomy was a comparatively simple proceeding. In his gastro-intestinal work Pauchet chiefly uses straight glovemaker's needles, though in certain places he changed to curved ones. In gastro-enterostomy he uses collargol catgut throughout, fearing gastro-jejunal ulcers from the use of unabsorbable threads; in gastrectomy the serous sutures were of fine linen. Unlike many French surgeons, Pauchet works in fine rubber gloves till the suture of the wall, when he changes quickly into the thick Chaput gloves. Anæsthesia was always spinal, paramedian and local if possible. In some cases these methods were satisfactory, in others ethyl chloride or ether had to be used in addition.

Choledochotomy.—The patient, a fat male, was anæsthetised by spinal anæsthesia, and a long incision made parallel to the right costal margin, and about one inch from it. From the outer part of this incision another led vertically downwards, ending at or below the level of the umbilicus, and three or four inches external thereto. The exposure was admirable in an obviously difficult case. Under the liver the fundus of a shrivelled gall-bladder was barely visible in adhesions. Grasping it with Kocher's forceps the operator cleared the gall-bladder by knife dissection, chiefly from the stomach, in an attempt to define the cystic duct. This, however, proving impracticable, mobilisation of the duodenum was at once commenced by clean dissection with the knife. Gradually the common duct, obviously thickened, became visible. Incision was made into the duct between two Kocher's forceps, bile and biliary mud exuding.

The duct was sounded upwards and downwards with a curved steel urethral bougie, a calculus being struck far down in the duct. Manipulation of the stone pushed it upwards towards the incision, and on extraction it appeared the size of an olive. The duct was drained by a T-shaped tube, which fitted snugly into it; alongside the tube a couple of thin strips of gauze were left, to be removed gradually about the fourth day. The large wound was carefully sutured by thick catgut in the peritoneum and posterior sheath and in the anterior sheath; in addition here and there sutures of fishing gut were inserted. Michel's clips closed the skin.

During the operation, which was rapidly performed and conspicuously free from bleeding, only two intra-abdominal ligatures were placed, one on the round ligament of the liver, the other a single suture in the duct. When asked by a spectator why he left the gall-bladder, Plauchet replied that it was so shrivelled as to be no longer a gall-bladder; its removal was therefore unnecessary and only conducive to hæmorrhage, difficult to control in this case from the difficulty of access to the cystic duct.

Excision of a cancerous rectum.—The patient, a stout male, under spinal anæsthesia, was first placed on his back and a loop of the transverse colon fixed in the wall through an incision in the left rectus at the level of the umbilicus. This was done by slight omental separation, to define clearly the mesocolon on its upper surface, the bowel being slung up by a couple of fishing-gut sutures, passing through the mesocolon, each suture being tied on the skin, mattress fashion, on its own side. The bowel was to be opened 48 hours later. The patient was now turned on his face in the reverse Trendelenburg position, the buttocks being so raised that operator and assistant had to stand on small stools. The anus was closed by a silk suture and the anal canal dissected till about 3 inches were displayed. An incision was then made in the middle line over the sacrum and coccyx, stopping short of the perianal incision. The coccyx was removed and from the space thus left a pair of forceps was passed downwards and gripped the anal ligature. Traction on the ligature drew up the dissected anal canal into the space left by removal of the coccyx and careful dissection of the bowel from the prostate was begun, the gland soon showing bare at the bottom of the wound. Freed from the prostate, the bowel was rapidly detached with the perirectal fat from the sacral hollow; the peritoneum was opened and the lateral vessels on the rectum secured. A ligature was then placed round the bowel well above the growth, which was cut away, and the bowel was brought down and stitched to the skin at the anus. To avoid tension some lateral stitches fixed it to the sides of the cavity into which a couple of drainage-tubes and a mesh of gauze were placed, the large wound being reduced by a few separate fishing gut sutures. The anæsthesia of this operation was complete and its performance was marked by the absence of bleeding.

De Martel's Inventions and Methods.

T. De Martel had a list of over two dozen cases for operation, including craniectomies, laminectomies, abdominal and rectal surgery. His book on "Injuries of the Skull," published in the Horizon series, has already been translated into English. De Martel is the inventor of a craniotome and an ingenious crushing clamp for the stomach. In one morning he performed two appendicectomies, resection of a cancerous breast, removal of an ovarian cyst, gastrectomy for cancer, and craniectomy as a decompression operation.

In appendicectomy he simply ligatures the appendix stump after cutting it through with the cautery and drops it back into the abdomen without invagination. In a case of cholecystectomy in a very fat woman, he used Perthe's incision, removing the enlarged gall-bladder rapidly from below upwards. A rubber drain was placed near the stump of the cystic duct, but not fastened to it. Beside the drain a couple of gauze meshes were put in and the wall closed by one layer of through-and-through sutures of aluminium-bronze wire, a method of suture which in a case like this seemed very insufficient to some of the onlookers. In a case of duodenal ulcer he performed exclusion of the pylorus by cutting across the pyloric antrum. Each end of the gastric section was closed and posterior gastro-enterostomy performed on the upper end. De Martel's craniectomies are anæsthetised by about 5 ounces of ether in oil per rectum, then local anæsthesia by novocaine and adrenalin is used in a very thorough way. The condition of a patient two days after a decompression operation was most satisfactory.

In a case of supposed tumour of the spinal cord a physician first gave a brief history of the case, De Martel also making some remarks on the diagnosis. Laminectomy was performed under ether anæsthesia, but no tumour or collection of liquid was found and the wound was closed, De Martel remarking that the condition must have been an intraspinal lesion. At the close of this operation a girl of 22 walked into the theatre before her less fortunate companion had been wheeled out. She had had laminectomy performed two months previously for a tumour in the spinal canal, and she was obviously in a very satisfactory condition, all paralysis having disappeared.

De Martel has recently published his results in 20 cases of tumours of the cord and its membranes, and in this interesting report the details of technique are fully given.[1] Pauchet and De Martel both speak English, so that English-speaking surgeons can always get information on any point.

Anastomosis by Pierre Duval.

Professor Pierre Duval, operating at the Lariboisière Hospital, performed a choledochotomy, an operation for gastric ulcer, and one for intestinal stasis caused by adhesions.

1. *Choledochotomy.*—Duval explained that the patient, a female, suffered from obstructive jaundice, and that the provisional diagnosis was stone in the common duct. The incision was of the Mayo Robson type; the gall-bladder being cleared of adhesions, cholecystectomy was performed from below upwards. The stone, occupying the junction of the cystic and common ducts, was about 1½ in. long, and was quickly removed. Drainage of the duct was by a soft catheter with a mesh of gauze placed beside it; suture of the wall was

---

[1] Bulletins et Mémoires de la Société de Chirurgie, Paris, vol. xlv, No. 2, pp. 511 to 521.

in two layers. At the close of this operation Duval handed round the most curious radiogram of biliary calculi by Beclerc the present writer has ever seen; four to five stones were perfectly visible in the gall-bladder, and lower down and inwards others could be seen in the track of the common duct.

2. *Ulcer of the lesser curve.*—Duval said that a radiogram showed an ulcer in this position and that he intended doing Balfour's cautery operation. A median incision was followed by omental colic separation and exploration of the posterior surface of the stomach showing the ulcer adherent to the liver and pancreas. On attempting mobilisation of the lesser curve the ulcer tore; Duval therefore desisted from further attempts at separation from the liver, and with the cautery simply seared the edges of the large resulting gap. Suture of the gap by some separate catgut sutures with a Reverdin needle was followed by a layer of serous sutures burying the first. He then performed posterior gastro-enterostomy without clamps, and when asked by a spectator what direction he gave to the jejunal loop he replied that it did not matter, as the essential for a successful gastro-enterostomy was a large anastomosis at the lowest part of the stomach near the pylorus. The opening did not appear to be more than one and a half inches long. At the end of the operation Duval explained that he had not wholly done Balfour's operation, which was obvious.

3. *Intestinal anastomosis for post-operative adhesions.*—The patient had a long vertical scar in the left flank, the result of some previous operations. Loops of large bowel were found matted together in the left iliac fossa. The adhesions were separated as far as possible, and as some angulation persisted between the separated loops, Duval performed anastomosis between two loops. He did not use clamps, and sutured the bowel with a fine Reverdin needle, cleaning the cut surface with swabs soaked in ether. He explained that he used this needle even for gastro-intestinal sutures as he was so accustomed to its use. Though a useful instrument in sutures elsewhere, this needle obviously makes a larger hole in the tissues and cannot be manipulated any faster than a straight or conveniently curved intestinal needle used by the fingers.

In connexion with the Congress an interesting exhibition of surgical and electrical instruments was arranged in the hall of the Faculty of Medicine.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Council of the Irish Medical Association.

A QUARTERLY meeting of the Irish Medical Association was held in the Royal College of Surgeons, Dublin, on Jan. 14th, Dr. J. Marshall Day, the President, in the chair. Correspondence was read between the secretary of the Association and the Chief Secretary for Ireland dealing with the difficulties arising out of the Motor Permits Order. The Association had asked for some special consideration in the case of drivers employed by medical men, but the Chief Secretary declined to grant the request. The following resolution was passed unanimously:—

> "The present position regarding the Motor Permits Order seriously interferes with the attendance on sick persons throughout Ireland. The Council of the Irish Medical Association believes that the object of the Order would be best met by a photograph of the driver being affixed to his licence, and requests the Government to adopt this course."

This is the suggestion which has already been put before the authorities by the Traffic Controller for Ireland. A discussion followed concerning the inadequacy of the fees at present paid for examinations for life assurance, and the following resolution was passed:—

> "That the scale of fees for examinations for life assurance shall be as follows: Proposals for £100 and under £500, £1 1s.; £500 and over, £2 2s."

The Council discussed the inadequacy of the remuneration given for attendance on the officers and men of the Royal Irish Constabulary, and a deputation was appointed to wait on the authorities to ask for a reconsideration of the present scale of payments and conditions of service. Discussions took place concerning the working of the Reorganisation Committee and the Irish Public Health Council.

The Royal Academy of Medicine in Ireland and the "Dublin Journal of Medical Science."

The Council of the Royal Academy of Medicine in Ireland has recently acquired the goodwill of the *Dublin Journal of Medical Science* and has decided to make it in future the means of publishing the Transactions of the Academy. Since the formation of the Academy of Medicine in 1882 it has, until 1917, published its Transactions in an annual volume. Since 1917 no issue has appeared. The *Dublin Journal* has a long history. It has reached its 149th volume, and the current issue is No. 576 of the Third Series. With the issue for March it will commence its Fourth Series under its new auspices. The present editor, Sir John W. Moore, has had charge of the journal for nearly 50 years, and much credit is due to him for the high literary standard maintained by the journal and for the determination which has kept it alive through many difficulties. The Council of the Academy has decided to offer the editorship of the journal, when it comes into their hands, to Mr. Arnold K. Henry, F.R.C.S.I.

The Belfast City Council.

At the time before the recent municipal elections there were three medical representatives in the Belfast City Council. Of these, one did not again come forward, and of the other two candidates only one, Dr. J. D. Williamson, was elected.

Jan. 19th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENT.)

Improving the Indian Medical Service.

CERTAIN proposals of the Government of India were sent home some time ago, although the report of the Medical Services Committee has not yet been finally considered. One of the principal grievances of the officers of the service, as is well known, is the difficulty and uncertainty of obtaining leave or furlough home. It is high time that steps were taken to remedy this grievance, not merely from the paramount necessity of relieving the hardships of a class of officers who have rendered splendid service to Empire, but also from the urgency of the problem presented by the difficulty of recruitment. Since August, 1914, the total number of I.M.S. officers has steadily declined from 775 to 732. On the civil side there are now just over 200 officers on duty as against 507 before the war. There were nearly 200 permanent I.M.S. officers employed overseas, principally in Mesopotamia and Egypt, whose services cannot yet be spared by the military authorities. Now, as has already been stated, the total number of I.M.S. officers is less than the total sanctioned pre-war strength plus the 23½ per cent. study and leave reserve. Quite apart from the increase of this reserve, which, it is anticipated, will be among the contemplated improvements, the military requirements of India, due to revised scale of treatment and to the inclusion of the treatment of departmental followers in Indian station hospitals, will necessitate an increased cadre. Leaving out of consideration the 200 officers now serving overseas, some 150 officers are necessary to make up the shortage. It is plain that if the hundred or so European doctors required by recruitment formula—"two Europeans and one Indian"—are to be found, the attractions of the Indian Medical Service must be greatly increased.

Esher Committee on the Indian Military Services.

Commenting on the work before the commission the leading Indian journal says: "We trust that the committee will give the widest possible interpretation of its instructions; for it is high time that the whole military condition in India was reviewed in the light of the requirements of modern warfare and the calls likely to be made on India in the not distant future to bear her share in the carrying out of a general scheme of Imperial Defence. Is the health and comfort of the soldier looked after as it should be? Are military cantonments and hospitals models of their kind? Is electricity in general use in our military barracks and are water pipes laid down in every large cantonment? Has the motor lorry everywhere replaced the bullock-cart and made mobile columns really mobile? The plea that funds are not available cannot be allowed any longer to stand; we must find the funds to make our army really efficient, even if we have to revise all our ideas as to what is necessary and unnecessary from a military point of view. And here the Esher Committee, if it will but devote itself to discovering a solution to this problem, will confer a real benefit on the Government, army, and people of India."

Anti-plague Measures in Secunderabad.

The laying of the foundation-stone of a rat-proof grain market took place a few days ago in Secunderabad. This is one of the effective measures adopted by local administration to combat plague. The building will cost Rs.1¼ lakhs (£12,000), and will include 27 store-rooms in addition to a handsome façade to be occupied by cloth shops; its location in the centre of the town, close to the general market, will render it convenient in every way to the public and also to the merchants.

Cholera near Calcutta.

A virulent type of cholera is reported to have broken out at the coolie depôt near Calcutta. Four or five cases are being reported daily, and some have proved fatal.

Public Health in Calcutta.

The Governor in Council has decided that the time is ripe for a thorough investigation into the existing organisation of the Public Health Department of the Presidency of Bengal. He desires that the organisation should be examined and that proposals should be made with a view to rendering it adequate to discharge the expanding functions which in the near future must inevitably be assigned to it. The Government has accordingly decided to appoint a committee, consisting of the following gentlemen, to advise upon the whole subject, viz.:—Hon. Mr. C. F. Payne, I.C.S., chairman; Dr. C. A. Bentley, M.B.; Sir L. Rogers, Kt., I.M.S.; Sir Nilratan Sarkar, Kt., M.D.; Nawab Khwaja; His Excellency in Council Muhammad Yusuf Khan Bahadur Rai; Jadu Nath Mazundar Bahadur; Dr. J. W. Tomb; and Mr. S. W. Goode, I.C.S., as whole-time secretary. The Committee has been given broad terms of reference, and it is hoped that a comprehensive scheme will be drawn up.

The Health of Baghdad.

Baghdad is, I learn, at present free from any form of serious disease. Influenza certainly is running its course through the town, but it is not of the dangerous nature from which so many suffered last year. The Civil Hospital is making steady progress, and is daily becoming more and more popular with the population. The ophthalmic section, in particular, is doing valuable work, and in consequence of the results which are effected many Arabs who have previously carefully avoided the "nakim" are bringing their children for treatment. The dental section, which has recently started, has already attained a remarkable degree of popularity.

DEATH OF MR. S. RYAN.—Mr. Simon Ryan, who died suddenly at his residence, Ecclesall-road, Sheffield, on Jan. 5th, received his early medical education at Queen's College, Belfast, and gained the Malcolm exhibition at the Royal Hospital, Belfast, in 1886. Later he went to Edinburgh University, and qualified in 1889 with the Scottish triple qualification, obtaining the Fellowship of the Royal College of Surgeons, Edinburgh, in 1903. Mr. Ryan, who had practised in Sheffield for some 30 years, was 61 years of age, and leaves a widow and two sons, one of whom qualified in 1914 and has assisted his father in practice.

Correspondence.

"Audi alteram partem."

THE PREVENTION OF VENEREAL DISEASE.

To the Editor of THE LANCET.

SIR,—The statement of the general secretary of the National Council for Combating Venereal Diseases, published in THE LANCET of Jan. 17th, indicates clearly that the Council is not even now, after so much severe criticism, aware of the actual situation. Between it and the Society for the Prevention of Venereal Disease there is more than a mere difference of opinion as to the best means of controlling venereal disease. Rightly or wrongly, a belief has arisen in many minds that the Council is either very blind to plain evidence, or else is not sincere in the desire, which apparently it now professes, to prevent the spread of venereal disease by any and every means which would be applicable to any other infectious malady. It is necessary to use plain words, for, if the belief be founded on error, then the more plainly it is expressed the more easily it can be rebutted. It is this suspicion which is the controlling factor. It led more than anything else to the foundation of the S.P.V.D. The Council professedly bases its activities on the findings of the Royal Commission of 1913, the Inter-Departmental Committee of 1919, and on Lord Sandhurst's statements in the House of Lords in November last. But surely it is aware of the deep distrust which all these inspired.

The history of the Royal Commission is well known. Seven years before it began its labours two great discoveries had been announced—Ehrlich's discovery of salvarsan and Metchnikoff's discovery that syphilis could be aborted by the early inunction of calomel. The proceedings and Report of the Royal Commission are full of allusions to salvarsan. At the time the Commission completed its labours (1916) 20,000,000 fighting men were being protected by Metchnikoff's discovery, yet during the whole of the proceedings not one question was asked concerning it in its application to man, and in the Report it is alluded to in only a single sentence, which is not even indexed. Some of the medical members of the Commission desired to give prominence to it, but were unable to carry their point.

The Royal Commission expressed the opinion, chiefly on the authority of the late Sir William Osler, that syphilis ranked as about the fourth killing disease, and that about 10 per cent. of the inhabitants of the great towns were actually suffering from it—i.e., about 3,000,000 people in the United Kingdom. Gonorrhœa is five or six times as common. It would appear, therefore, that about every other person, certainly at least every other male, has suffered from venereal disease. For the mitigation of this enormous pestilence the Royal Commission recommended preaching to adults and an extension of treatment by means of salvarsan. In express terms it handed the good work to the National Council. "When we drew up the regulations of the Society (i.e., Council) care was taken to avoid suggesting that means should be taken to prevent infection." But was ever a pestilence stayed by preaching and treatment? Moral lectures given to adults are confessedly futile. Fear of disease does not prevent incontinence, even among medical students, who know so much. An attempt to stay a plague of such dimensions by treating the sick is like trying to empty the Atlantic with a teacup.

The raising of the new armies for the war was accompanied by a vast outbreak of venereal disease among them. We heard little of this epidemic because allusion to it was suppressed for fear of the effect on recruiting, but at one time the Colonial Governments threatened to withdraw their forces unless means were taken to protect them, and in every dominion the main election cry of those who opposed assistance to the mother country was that the young men should not be sent to this cesspool—England. As a consequence, early in 1916—about the time the Royal Commission was issuing its report—the Government was forced to take measures to protect the troops. It is understood that some sort of arrangement was made with "influential people" who opposed "any system of prophylaxis which might be said to afford opportunities for unrestrained vice." Therefore the Government did not supply the troops with "packets" with which they could disinfect themselves immediately after exposure: it established instead "venereal ablution rooms," in which were pails of permanganate lotion and pots of calomel ointment. The men could not disinfect immediately; they had to return to barracks first.

The surgical fevers—septicæmia, gangrene, tetanus, and the rest—are contagious diseases. Every surgeon is of the opinion that whoever delays disinfection for their prevention is a lunatic or a criminal. The venereal diseases are also contagious diseases. They differ from the surgical fevers in that the pathogenic organisms are of exceptional delicacy, in that the time and place of infection may almost always be anticipated, and in that the male organ is so shaped and situated that it is easily disinfected by the individual himself.

Before the war the 1st Battalion Yorkshire Regiment was ordered to Delhi, a hot-bed of venereal disease. The M.O. advised his men to swab themselves immediately after exposure with a solution of permanganate. In four years he saw only six cases of venereal disease, a rate of 1·5 per 1000 per annum. At Mhow venereal disease was reduced to "negligible proportions" by the same means. At Portsmouth an M.O. who had charge of 2000 troops for 28 months also achieved a venereal rate of 1·5. The method spread in the area, and many other M.O.'s obtained similar results. At the local venereal diseases hospital it was found that not one man who had disinfected himself immediately had acquired disease. At Whale Island, the Naval Gunnery School, Surgeon-Commander P. H. Boyden gave bottles of permanganate solution to 496 men, none of whom acquired disease except one who delayed disinfection six hours after exposure. Among the Royal Marine Artillery, who were also taught to disinfect quickly, there were five infections in nine months among nearly 4000 men—a rate approximately of 1·5 per 1000 per annum. Generally speaking, this rate appears to be the normal for troops carefully instructed to practise quick disinfection. Many more instances could be given, but only those which can be exactly verified from official records are quoted.

In 1918 the Government, impressed by the evidence, ordered the provision of prophylactic packets. Protests were immediately raised by those who desired quick disinfection. It was pointed out that it was not "packets," but instruction, that the troops needed. They had disinfectants in abundance. However, whoever was now in charge of the arrangements for preventing disease persisted. After prolonged delay the packets arrived with instructions that they were to be used in the old inefficient way, with delay. Protests were again raised, but were again unheeded. If any officer or man who served during the war be questioned, it will be found in 99 cases out of 100 that he received no instructions whatever. It seemed to the medical officers who were achieving almost perfect results by means of careful instruction and quick disinfection, that someone in authority was inefficient, or else was not desirous of the success of quick disinfection. Meanwhile they had no choice but to persevere and hope that their example would bear fruit later. In the army taken as a whole the venereal rate remained at about 40 per 1000 per annum.

After the end of the war an Inter-Departmental Committee considered the question of the prevention of venereal disease among the civil population, and founded its conclusions mainly on imperfect and ill-considered statistics supplied from the army. Not only did these statistics record the results of incompetent administration, but from the whole results only those were selected which would serve to make the case for quick disinfection appear worst. For example, the high rate of venereal disease among the Australians is mentioned, but nothing is said as to the shocking carelessness of the Administration, nor of the splendid results achieved when care was taken, as, for instance, by Colonel Elgood at Port Said. No stronger condemnation of the administration in the British Army could be penned than this statement of the Inter-Departmental Committee itself: "The returns from individual units appear to show that a reduction is effected only when the medical officer takes a very special interest in the subject and neglects no opportunity of impressing the importance of prompt disinfection on the men under his charge." *Think of this being written of enteric fever or any other disease which was enormously reducing the strength and efficiency of the forces.*

It is not necessary, however, to deal with the Inter-Departmental Committee at length, except to say that indignation at its proceedings led directly to the foundation of the Society for the Prevention of Venereal Disease. It is sufficient to consider the statements of Lord Sandhurst, whose figures are of the same character and derived from the same source as those of the Inter-Departmental Committee. Lord Willoughby de Broke asked for information concerning the Portsmouth area—the area administered by the Assistant Director of Medical Services at Portsmouth—in which careful teaching and quick disinfection had been practised. He wanted to learn about the effects of this quick disinfection, and his object was perfectly understood, if not by Lord Sandhurst, at any rate by the person who supplied him with his figures. Besides the disease contracted by troops resident in the area, much was brought into it during 1919 by drafts, and whole units from elsewhere. Within the area, too, but not in the care of the A.D.M.S., were large bodies of Americans, Colonials, and R.A.F., all of whom had an exceptionally high rate of infection. Lord Sandhurst lumped together all the disease occurring in or imported into the area—which is absolutely the model area for the whole kingdom—and declared that it was two and a half times as high as for the rest of the kingdom. He was immediately called to account, but the Council continues to quote his statements as trustworthy. The remarkable thing is that Lord Sandhurst's arguments make the case even more deadly against the Council than the actual facts. According to him the venereal-rate in the Portsmouth area is about 100 per 1000 per annum. In Portsmouth itself, the only large town in the area, it should be therefore about 150 per 1000 per annum. But among 7000 troops in that town it was reduced to 1·5 per 1000 per annum by quick disinfection and careful teaching. Could anything be more decisive? All that is in this letter and much more has been brought to the attention of the National Council, which still seems to think that the mere opinions of the Royal Commission, the Inter-Departmental Committee, and Lord Sandhurst require only simple quotation, not justification.

We wish to add that, as far as we know, there is no warrant or justification for the secretary of the N.C.C.V.D.'s statement that "the S.P.V.D. consider that immediate self-disinfection is the only measure worthy of consideration," &c., and that the claim made by the N.C.C.V.D. for being the only representatives of those who have had intimate experience of the problems involved in the successful *prevention* of venereal disease is clearly unfounded. For that body is mainly composed of those who have had no experience of immediate disinfection, and have persistently discouraged all trials of it. We are, Sirs, yours faithfully,

H. BRYAN DONKIN.

THE CAUSATION AND PATHOLOGY OF DIVERTICULITIS.

To the Editor of THE LANCET.

SIR,—In reference to the recent discussion on diverticulitis I think it of interest to point out that I described the diverticula and demonstrated their causation in a paper entitled "The Pathology of Extravasation of Urine" in Guy's Hospital Reports in 1885. The paper was written with the object of showing that the universally accepted theory of the causation of extravasation which was put forward by the then great authority on the subject was absolutely false.

The following was extracted from an article written by Sir Henry Thompson in Holmes's "System of Surgery."

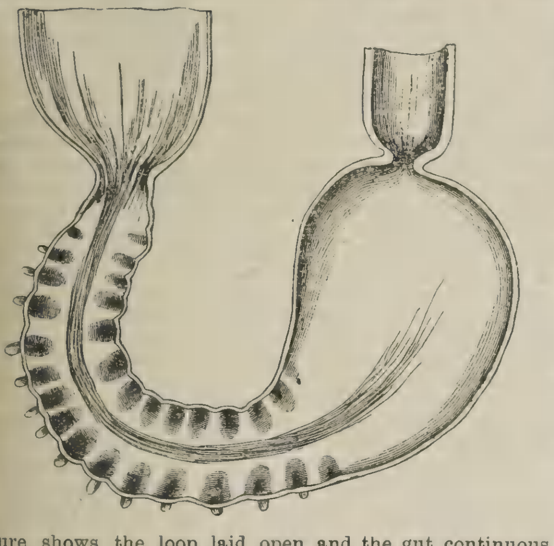
"Extravasation of urine takes place during unrelieved retention by the giving way of the urethra at some point. It is very rare indeed that the bladder itself is ruptured. In either case, however, mechanical distension is not the direct or only cause. Ulceration of the mucous membrane behind the stricture leads to a breach of the urethral walls. The bladder contracting drives the urine with great force into the cellular tissue around, so that it soon reaches the superficial fascia of the scrotum, abdomen, &c."

I do not intend to go into this question in detail here except to state that extravasation results not from any giving way of the wall of an ulcerated urethra, but from the rupture of a periurethral abscess that had burst into the urethra behind the stricture. I was able to demonstrate the truth of this beyond any doubt, as we had at that time a large mortality from extravasation, most of the patients having had a Cock's operation performed on them.

The study of extravasation led me to that of sacculi of the urethra, prostate, bladder, and intestine, and also of aneurysms.

The case of diverticulitis to which I wish especially to call attention illustrates so clearly the manner in which diverticula are formed in the bowel that it requires no further comment from me. The following is an extract from my report on the pathology of the patient's intestine:—

"On opening the sac of the large acquired hernia on the left side, a piece of omentum was found attached to its lowest point. Its upper extremity was free, and presented a cicatricial contraction. Lying on the neck of the sac and adherent to it was the end of a piece of omentum which presented a cicatrix corresponding to that of the lower piece. Occupying the sac was a single loop of large intestine, which with its mesentery was loaded with fat. It was adherent near its neck and posteriorly. The loop of gut measured nearly a foot in length. On laying it open that end which was on the abdominal side of the internal ring was seen to be much dilated, while the proximal end of the loop was very narrow, and presented a double row of sacculi separated by a prominent ridge formed by the band of longitudinal muscle fibres. The figure shows the loop laid open and the gut continuous with either end of the loop. Also the lower row of diverticula, from which the appendices epiploicæ have been removed. Though the diverticula were placed in the appendices epiploicæ their position there was apparently accidental, for the reason that the diverticula, like the appendices, were only seated in the intervals between the longitudinal bands. At the bottom of most of the depressions were small circular openings leading into dilated processes of the mucous membrane covered by a thin layer of the mucous coat. In many of these sacculi the muscle covering appeared to be absent; in character they resembled the diverticula seen in the bladder. The distal half of the loop increased gradually in calibre, losing its sacculated appearance, the prominent ridge of longitudinal fibres becoming indistinct, and then disappearing in the distal extremity of the loop, which was very much dilated. The piece of gut continuous with this in the abdomen opened into the dilated end by a very small constricted orifice, resembling in appearance the œsophageal opening into the stomach. This part of the intestine was contracted and was not unlike the œsophagus, its walls being thick, its calibre small, and its mucous membrane arranged in close longitudinal folds. The contraction of the proximal half of the loop in a transverse and longitudinal direction had resulted in the formation of the prominent longitudinal ridges and the formation of the sacculated appearance. The diverticula of the mucous membrane were evidently produced in the same way, as were the corresponding diverticula in the bladder—namely, by the vigorous contraction of this portion of the loop on its contents, forcing them into the distal half, which on that account became enormously dilated. The very small size of the orifice of communication with gut in the abdomen and its position formed a considerable and a progressively increasing obstacle to the passage of fæces into it."



This man had also a very tight stricture of the urethra, and his hypertrophied bladder presented a large number of diverticula varying in size from a depression to a sacculus as large as a walnut. Many of these vesical diverticula were simply pouches of mucous membrane which projected through the muscle wall, while in others there was a distinct coating of muscle fibre. The fat which was so abundantly present seemed to favour the formation of these herniæ. It is clear from a consideration of the above that the two factors in the development of diverticula are tension and fat, the infection being a natural sequence of stagnation of the contents of the diverticula.

I am, Sir, yours faithfully,

Jan. 18th, 1920. W. ARBUTHNOT LANE.

THE JUSTIFIABILITY OF THERAPEUTIC LYING.

To the Editor of THE LANCET.

SIR,—We have read Dr. C. S. Myers's and Dr. I. G. Cobb's criticism of Dr. Hildred Carlill's treatment of the boy with hysterical sleeping attacks reported in THE LANCET of Dec. 20th, 1919. We both saw the boy several times, and we wish to emphasise the fact that every effort was made to find an underlying cause for his mental state, but without success. It was only after all these measures had been tried and had failed, that Dr. Carlill decided to resort to the procedure which has raised such adverse criticism.

We are convinced that in his conduct of the case Dr. Carlill was actuated solely by the desire to benefit a patient who, as long as he remained uncured, was in danger of meeting an untimely end.

We are, Sir, yours faithfully,
E. A. COCKAYNE,
GEORGE E. S. WARD.

Jan. 20th, 1920.

THE PRIVACY OF VENEREAL CLINICS.

To the Editor of THE LANCET.

SIR,—With reference to your article "The Privacy of Venereal Clinics," and to other comments which have appeared on Mr. Justice McCardie's ruling as to the giving of evidence by a medical officer of a venereal clinic in regard to a patient who had been treated there, is not the essential feature of the case the fact that it was the patient who called the medical officer to give evidence that she herself had been treated for venereal disease? If this is so, the ruling surely involves no breach of the principle regarding secrecy that is guaranteed at venereal clinics, nor should it tend to destroy the trust of the public in venereal clinics. If medical officers were not allowed to give evidence in such cases it would restrict, to the detriment of the patients, the usefulness of such institutions.

The correctness of the above attitude may perhaps be made more apparent if one considers an analogous case. Imagine that a person had been seen to attend a venereal clinic and was wrongfully accused of having been treated for venereal disease. If such a person were not permitted to avail himself of the evidence of the medical officer of the clinic he would be inferentially placed in a very unfavourable position. A very different principle would be involved if a medical officer were called upon to give evidence by one party that another party had been treated for venereal disease; this, of course, would be a gross breach of professional etiquette, and I imagine that in such a case a medical officer would absolutely refuse, at whatever cost, to consent to what would not only be an infringement of the rules of venereal clinics, but a breach of the honourable traditions of his profession.

I am, Sir, yours faithfully,
A. MEARNS FRASER,
Portsmouth, Jan. 18th, 1920. Medical Officer of Health.

*** Certain daily papers missed the significance of the fact, mentioned in our columns and emphasised by Dr. Mearns Fraser, that the petitioner herself obtained the medical evidence.—ED. L.

THE MEDICAL MAN'S INCOME-TAX.

To the Editor of THE LANCET.

SIR,—In THE LANCET for Oct. 19th, 1918, there appeared an article by Mr. John Burns, W.S., entitled "The Medical Man's Income-tax." It is the most comprehensive and explicit paper on the subject that has appeared in my knowledge, and should be at every medical man's elbow when he makes out his annual return.

Among the abatements cited was one that particularly interested me. In a paragraph under "*War Work*" it was stated that the benefit of the reduced rate of tax, *on the pay only*, is available to all who, in the tax year in question, have served in service of a naval or military character in connexion with the war, for which payment is made out of money provided by Parliament. Having served throughout the war as medical officer in sole charge of a military hospital here, the pay for which appointment was of the nature of consolidated pay, and coming by monthly cheque from Eastern Command Headquarters, it appeared to me that I was, under this regulation, entitled to the service rate on this pay. I accordingly made claim to the reduction by appealing in the first instance to the local surveyor of taxes. That official replied (Oct. 21st, 1918) that he had to inform me that the special rates applicable to army and navy pay are only allowed in the case of men actually on active military or naval service. "The fees received by you are assessable at the ordinary rates of tax." This reply was in such flat contradiction to Mr. Burns's statement, made evidently with complete knowledge of the case, that I lodged a formal protest with the surveyor while I inquired further into the matter.

Through the courtesy of the Editor of THE LANCET I got into communication with Mr. Burns. I pointed out to him the discrepancy between the statements in his article and the dictum of the local surveyor, giving him details of the conditions under which I held the appointment. For the zest with which that gentleman leaped into the conflict which ensued for the next six months with the various Government departments concerned I cannot sufficiently express my admiration and thanks. I doubt not there are a large number of medical men entitled to the same relief as myself. It is with the hope that they will at once put in their claims and be as successful as myself that I am writing this communication. But I hope that they will not forget that they will owe their success entirely to the pertinacity and technical knowledge which Mr. Burns freely gave for the medical profession.

The whole correspondence makes quite interesting reading, but as it would fill many pages of your journal, the course of it can only be indicated. A fight with a Government department is as good a game as Rugby, if you know how to play it. But it is a game only experts can play at. As soon as one department is in danger of being tackled the ball is "passed," and the game kept going in the hope that the opposer will tire. But Mr. Burns proved himself a master at the game. The way in which he stuck to the man with the ball and finally brought him down was delightful to me, the onlooker.

The first move was a letter to the Chancellor of the Exchequer fully setting out my case. The reply was a brief note, not from the Chancellor, but from Somerset House, that the Board of Inland Revenue do not regard "temporary civilian doctors employed at war hospitals" as falling under the War Service Relief. Mr. Burns rejoined that he wrote not to the Board of Inland Revenue but to the Chancellor of the Exchequer. He pointed this out to the Board, and again wrote to the Chancellor requesting him to give the matter his personal consideration (3/12/18). On Dec. 30th Mr. Burns writes, "I have at last got the Chancellor of the Exchequer to write upon the subject, although not very fully. I infer that his sympathies are with you, but he treats it as primarily a matter for the War Office. In that I think he is wrong, and I am saying so. I am, however, writing to the War Office, and I am sending a copy of that letter to the Chancellor." There followed (Dec. 30th, 1918) a long and closely reasoned letter to the War Office, in which the whole case was again set out, as being really representative of that of the profession. Pending a reply to this Mr. Burns drafted a series of questions to be put as soon as Parliament assembled to the departments concerned, asking, among other things, if the Treasury would provide funds for a test case being brought to the High Courts. These were kindly put by Sir W. Watson Cheyne soon after Parliament met, but the answers were non-committal.

The grounds of controversy gradually narrowed to a simple issue. The statute gave privileges to two classes of persons: (1) Those actually serving in the naval or military forces of the Crown; and (2) persons engaged in service of a naval or military character in connexion with the war. In refusing to acknowledge that my work was "service of a naval or military character," it was a fair question to ask for the official view as to what constitutes such service when rendered by one who was *not* a member of the military forces of the Crown. In a letter (War Office, Feb. 7th, 1919), for the first time, the official view was forthcoming. The instance given was "mine-sweeping." This was at once seized on by Mr. Burns as "singularly unhappy," for those engaged in mine-sweeping are separately covered by the same enactment as being for "three months master or member of the crew of any ship or fishing boat." *Ergo*, whatever class (2) means, it cannot mean *that*. Again, in the same letter the War Office postulates "active service," thus, as Mr. Burns points out, putting a gloss upon the statute, making an amendment rather than an interpretation of the statute.

Finally (April 24th, 1919) the War Office regrets that "it is not in a position to assist you further." It proceeds that the proper course for your client to adopt, should he wish to pursue his claim to the reduced service rate of tax, is to appeal to the District Commissioners of Income Tax, the authority appointed by law for the purpose. Accordingly I put in an appeal to the District Commissioners. I was not required to appear before them, the appeal being allowed. I have to-day received a draft for the amount—i.e., the difference between the service rate and the ordinary rate on the three years income from the appointment.

I think there may be many medical men similarly circumstanced to myself affected by this decision. One of my colleagues in this town, who through the war served as medical officer of health to the garrison, and also in medical charge of troops, has already had a similar claim allowed.—I am, Sir, yours faithfully,

Felixstowe, Jan. 17th, 1920. C. G. HAVELL.

BRITISH MANUFACTURE OF INSTRUMENTS OF PRECISION:

A PERTINENT QUESTION.

To the Editor of THE LANCET.

SIR,—May I call the attention of the medical profession to what, in my view, is an undesirable condition of affairs in these days when, as we are led to believe, every effort is being made to capture trade in instruments of precision. Many years ago I obtained from the firm of Carl Zeiss and Co. some hand spectroscopes, on the Browning model. These were, as they should be, furnished with a *wave-length* scale which was most admirably adjusted, and enabled the observer at once to read off the position of any absorption bands seen in the spectrum of the object examined. These spectroscopes having been stolen I was forced to obtain some of British manufacture, and to my great regret found that the old and unscientific, because purely arbitrary, scale was affixed to them. Doubtless it is true that by dint of great pains one can manage to construct a wave-length scale curve to coincide with this old scale; but even then one has perforce to refer to the curve at each observation, which causes a loss of time and, too often, a regrettable expenditure of language.

Is it not possible for our British makers of spectroscopes—even the most eminent of them—to take a leaf out of the book of Zeiss and make *modern* instruments?

I am Sir, yours faithfully,

Calcutta, Dec. 18th, 1919. W. D. SUTHERLAND, M.D.

THE NEED OF OPHTHALMIC PHYSICIANS FOR THE ADVANCEMENT OF OPHTHALMOLOGY.

To the Editor of THE LANCET.

SIR,—My paper on the Need of Ophthalmic Physicians for the Advancement of Ophthalmology[1] was read before the Section of Ophthalmology of the Royal Society of Medicine on Nov. 5th last, and adjourned for discussion to the next meeting, Dec. 3rd. The Section asked that the paper should be printed and circulated. This, however, was subsequently vetoed by the Council on its own responsibility. Recognising the many difficulties which were involved in the change of system advocated in my paper, I had prepared a resolution referring the subject to the Council of the Section for consideration and report, and had given notice to the secretary of the Section a week in advance. At the meeting, however, Mr. Holmes Spicer, the President, informed me that he would rule my motion out of order as it did not concern the affairs of the Section, giving me no time to remodel my motion so as to bring it into line with his ruling or to find a seconder to it.

I venture to protest against that ruling, which appears to me against the interests both of the Section of Ophthalmology and of the Royal Society of Medicine. Surely any subject which the *Section* has power to discuss must be one that its *Council* has power to discuss. The Council has never, to my knowledge, been accustomed to take such a narrow view of its powers, but has included all subjects relating to ophthalmology. And again, if the Royal Society of Medicine has no power to discuss such a subject, where can it be discussed? But, quite apart from the general principle, I hold that the ruling is in opposition to the true interests of the Section, the success of whose meetings depends upon the adequate discussion of the subjects brought before it. Quite a large proportion of the papers and cases brought before the Section are on *medical* subjects, read by ophthalmic surgeons to ophthalmic surgeons. Physicians practically do not attend our Section, and if they did they are not familiar with the ophthalmic point of view. Thus these papers have no chance of enlightened discussion, for what surgeon is going to criticise another surgeon's *medical* opinion? The discussions are therefore shorn of much of their medical interest. Thus, in the interests of the Section I hold it is of vital importance that the physician should be brought into closer touch with ophthalmology, and that it is the duty of the Council to consider what steps should be taken to this end. My suggestion of the appointment of physicians (other than consulting physicians) on the acting staff of ophthalmic hospitals may not be the best remedy. It is open to the Council to suggest a better.

At the last meeting of the Section the President appealed to members for papers, stating that the secretaries had none in hand—clear evidence that all is not well with the Section. For there is a wide field for ophthalmic research, totally unexplored by the physician and only superficially cultivated by the surgeon, which would yield an abundant harvest. The gradual exclusion of the physician from our Section is also shown by the fact that both our secretaries are surgeons. In the mother society—the Ophthalmological—physicians took a large and active part in its formation and management, and up to a few years ago one of the secretaries was always a physician. On all these grounds I consider the position of the physician in relation to ophthalmology to be one which is not only of importance to our science, but of vital interest to the Section of Ophthalmology of the Royal Society of Medicine. For the Council to endeavour to burke the question is a dereliction of its duties.

I append a list of the medical subjects brought before our Section since 1912. It will be noted that four only were introduced by physicians, and in four other cases physicians took part in the discussion.

I am, Sir, yours faithfully,

Jan. 6th, 1920. RAYNER D. BATTEN.

List of Medical Subjects.

Disease in the Pituitary Region. J. B. Lawford. (Dr. Grainger Stewart spoke.)

A Case of Double Tubercular Iritis. Edgar Chatterton.

Glaucoma associated with Venous Congestion. Freeland Fergus.

Optic Neuritis, with Symmetrical Loss of the Lower Part of the Field, associated with Diabetes. M. S. Mayou.

Case of Bi-lateral Temporary Hemianopia; Rapid and Permanent Recovery of Vision after the Administration of Thyroid Extract. H. L. Eason.

Iritis, Rheumatic and Toxæmic. W. M. Beaumont. (Dr. F. G. Thomson spoke.)

Double Detachment of Retina in a boy with Albuminuria. Rayner Batten.

Amaurotic Family Idiocy in an English Child. E. A. Cockayne, M.D., and John Atlee, M.D.

Conical Cornea with Raynaud's Disease. C. Wray.

Retinitis of Pregnancy. J. Herbert Fisher.

Case of Pigmented Degeneration of the Retina associated with Epileptic Fits. F. E. Batten, M.D.

Disturbances of Vision from Cerebral Lesions, with Special Reference to Cortical Representation of the Macula. Colonel Lister and Dr. Gordon Holmes.

(1) Dilated Pupil of Argyll Robertson Type. (2) One-sided Internal Ophthalmoplegia. A. Hugh Thompson.

Neuro-retinitis after Chicken-pox. Leslie Paton.

The Retinal Signs of Arterio-Sclerosis Compared with those Due Simply to Increased Blood Pressure. Bardsley.

Discussion on the Ætiology and Treatment of Iritis. (Even here, *no* physician took part.)

Discussion on Nystagmus, held jointly with the Neurological Section.

Case of Pituitary Tumour. A. W. Ormond.

Pituitary Tumour (Hypopituitarism). L. W. Cargill. (Dr. James Taylor spoke.)

Case of Malignant Disease of the Pituitary Body, with Comments. G. Maxted.

Migraine. J. Herbert Fisher. (Dr. Gordon Holmes and Dr. James Taylor spoke.)

An Unusual Case of Ptosis with Bilateral Ophthalmoplegia Externa. M. L. Hine.

Changes in the Sella Turcica in Association with Leber's Atrophy. Dr. James Taylor.

MIND AND ITS DISORDERS.

To the Editor of THE LANCET.

SIR,—With reference to the pathology of some of the psychoses, and the connexion therewith of the psychoanalytic theories, I venture to suggest an hypothesis which I first brought forward at the annual meeting of the British Medical Association in Aberdeen in 1914. I shall try to put it as briefly as follows: Take, for example, a case of recurrent mania or melancholia. The mental condition is probably the result of a toxæmia of some kind. The hallucinations or delusions present may be analysed, and the nature of these and the reason of their existence explained by psycho-analysis. This procedure cannot, however, be expected to remove the illness which is dependent upon the toxæmia. A further illustration. A subject is given chloroform for a surgical operation. During one of the stages he is delirious. If his remarks are carefully noted and he be subsequently analysed the reason why his babbling took the particular form it did will probably be revealed, but the origin of the condition was the anæsthetic. I do not wish it to be understood that I think this hypothesis is applicable to all the psychoses, but a full discussion would far exceed the limits of a letter. With regard to the review which started this correspondence, I must confess that when I read it I was at first surprised, then saddened. It seemed to me most unfair.

I am, Sir, yours faithfully,

R. H. STEEN.

City of London Mental Hospital, Dartford, Kent,
Jan. 19th, 1920.

[1] THE LANCET, Nov. 29th, 1919.

THE INSTABILITY OF ROUS-TURNER BLOOD SUSPENSIONS.

To the Editor of THE LANCET.

SIR,—Professor G. Dreyer and Dr. A. D. Gardner, in their letter in your issue of Jan. 10th, state: "We did not use gelatin because its employment would have rendered our results incomparable with those of Douglas and Bigger, who did not make use of it." In our communication[1] we stated that we used "sheep cells washed and stored in the manner described by Rous and Turner." The method which we used was the one recommended by these authors[2] for the preservation of sheep cells. It is described in detail in their paper and, briefly, in the later paper by one of us (J. W. B.)[3] from which Dreyer and Gardner quote. In it gelatin is used in the washing but not in the preserving fluid.

We regret if our desire to make our paper as short as possible caused Professor Dreyer and Dr. Gardner to follow a method of preservation, different from that employed by us in our experiments.

We are, Sir, yours faithfully,
J. S. C. DOUGLAS,
JOSEPH W. BIGGER.

Sheffield, Jan. 15th, 1920.

URBAN VITAL STATISTICS.

(Week ended Jan. 17th, 1920.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at 16,500,000 persons, the annual rate of mortality, which had been 12·0, 16·2, and 15·8 in the three preceding weeks, fell to 15·6 per 1000. In London, with a population slightly exceeding 4,000,000 persons, the annual death-rate was 15·8, against 15·7 per 1000 in the preceding week, while among the remaining towns the rates ranged from 5·7 in Newport (Mon.), 9·0 in Smethwick, and 9·1 in Swansea, to 22·0 in Bootle, Preston, and South Shields, 22·6 in Tynemouth, and 22·8 in Barnsley. The principal epidemic diseases caused 327 deaths, which corresponded to an annual rate of 1·0 per 1000, and comprised 102 from measles, 75 from diphtheria, 62 from whooping-cough, 59 from infantile diarrhœa, 27 from scarlet fever, and 2 from enteric fever. Measles caused a death-rate of 1·5 in Nottingham, 2·2 in Barnsley, 2·9 in St. Helens, and 4·5 in Bootle; and whooping-cough of 1·3 in Portsmouth, 1·5 in Bootle, 1·6 in Birkenhead, and 2·8 in Gloucester. The 62 deaths from influenza were 11 less than the number in the previous week, and included 19 in London, 7 in Birmingham, and 3 in Oldham. There were 2758 cases of scarlet fever, 1945 of diphtheria, and 1 of small-pox under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, against 2809, 1899, and 2 respectively at the end of the previous week. The causes of 39 deaths in the 96 towns were uncertified, of which 6 were registered in Sunderland, 5 in Liverpool, and 4 in London.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual rate of mortality, which had increased from 13·2 to 16·6 in the four preceding weeks, fell to 16·1 per 1000. The 371 deaths in Glasgow corresponded to an annual rate of 17·4 per 1000, and included 4 from diphtheria, 3 from infantile diarrhœa, 2 each from measles and whooping-cough, and 1 each from enteric fever and scarlet fever. The 80 deaths in Edinburgh were equal to a rate of 12·2 per 1000, and included a fatal case each of diphtheria and infantile diarrhœa.

Irish Towns.—The 119 deaths in Dublin corresponded to an annual rate of 15·0, or 2·3 per 1000 below that recorded in the previous week, and included 2 each from whooping-cough and infantile diarrhœa, and 1 each from measles, scarlet fever, and diphtheria. The 166 deaths in Belfast were equal to a rate of 21·0 per 1000, and included 21 from measles, 7 from scarlet fever, 2 each from enteric fever and infantile diarrhœa, and 1 each from whooping-cough and diphtheria.

STRATTON (CORNWALL) COTTAGE HOSPITAL.—This hospital, which has been enlarged and improved, was formally opened by Sir Croydon Marks, M.P., on Jan. 6th. The hospital was founded in 1866, principally by the exertions of the late Mr. John King, M.R.C.S. An operating-room has been built by subscriptions to commemorate the memory of the late Mr. King, and a new ward containing five beds has been also erected.

Medical News.

UNIVERSITY OF BRISTOL.—At examinations held recently the following candidates were successful:—

SECOND EXAMINATION FOR THE DEGREES OF M.B., CH.B.

Part I.—Alexander Thomas Binnie, Sydney Harold Blacker, Arthur Paul Bodman, Ernest Gustave Bradbeer, Ernest Raymond Clutterbuck, Bertram Austin Crook, Bessie Veronica Frith Dawkins, Helen Mary Dixon, Robert Hugh Dummett, Georgina Roberts Dunn, Frank Robert Edbrooke, Norman Jack England, Prosper Gear Evans, Herbert Melhuish Golding, William Arthur Gornall, John Lysaght Griffin, Rowland Clifford Hatcher, Alexander Gordon Heron, Ernest George Hill, John Angell James, Frederick George Jenkins, Doris Ewing Joscelyne, Patrick Cathcart Joscelyne, Edgar Frederick King, Philip Heygate Knowles, Arthur Henry Marshall, John Raymond Nicholson-Lailey, Kenneth Frederic Platt, Arthur Skardon Prowse, Robert Arthur Sammons, Harry Leslie Shepherd, Arthur Erskine Sherwell, Hugh James Heaven Spreadbury, Herbert Taylor, and Robert Elliot Whitby.

Anatomy (completing examination).—Gilbert Bremridge Bush, Constance Lilian Griffiths, George Stenlake Mundy, and Millicent Taylor.

To Dr. R. T. Leiper, professor of helminthology in the University of London, has been awarded by the Senate of Glasgow University the Straits Settlement gold medal for his work in tropical medicine.

INDUSTRIAL RESEARCH AT GIRTON COLLEGE.—Girton College, Cambridge, has received from "A Friend" £10,000, both capital and interest to be applied during the next 20 years for the encouragement of scientific research by women in mathematical, physical, and natural sciences.

THE twenty-second annual dance given by the Middlesex Hospital will be held on Wednesday, Feb. 4th, from 9.45 P.M. to 3 A.M., at the Hyde Park Hotel, Knightsbridge. Tickets (21*s.* each) can be obtained from the honorary secretaries, Dance Committee, Middlesex Hospital.

THE Great Northern Central Hospital has inaugurated an antenatal clinic, which will be held weekly at the out-patient department on Thursdays. An additional session of the gynæcological department will be held on Thursday mornings, as well as on Monday afternoons, as hitherto.

WEST LONDON POST-GRADUATE COLLEGE.—The following lectures will be given on Fridays during the present session in the lecture room of the Post-Graduate College, West London Hospital, Hammersmith, W.

Jan. 23rd, 5 P.M. Professor W. M. Bayliss: Acidosis.
Jan. 30th, 5 P.M. Mr. MacMahon: The Treatment of Functiona and Organic Affections of Voice and Speech.
Feb. 6th, 5 P.M. Dr. R. Hutchison: Functional Dyspepsia.
Feb. 13th, 4.30 P.M. Mr. Hey Groves: Bone Grafting in the Treatment of Fracture.
Feb. 20th, 5 P.M. Dr. A. C. Jordan: The Radiography of Chronic Intestinal Stasis.
Feb. 27th, 5 P.M. Dr. J. S. Risien Russell: A Diagnosis of Affections of the Cerebellum.
March 5th, 5 P.M. Dr. Donald Hood: Some of the Clinical Aspects of Aortic Disease.
March 12th, 5 P.M. Sir A. Pearce Gould: An Old Clinical Lecture New Edition.
March 19th, 5 P.M. Professor Sir Clifford Allbutt: Kinds of Pneumonia.
March 26th, 5 P.M. Sir W. Arbuthnot Lane, Bart.: Intestina Stasis.

These lectures are open without fee to medical practitioners, who will be cordially welcomed.

ROYAL SANITARY INSTITUTE.—Commencing on Feb. 2nd, 6th, and 9th respectively courses of lectures and demonstrations will be given at 90, Buckingham Palace road, London, S.W., for (1) sanitary officers, (2) meat and food inspectors, and (3) women health visitors and child-welfare workers, the lecture hour in all cases being 6 P.M. Among the lectures for the first course, lasting three months, are Dr. R. King Brown, Dr. A. Greenwood, and Dr. Charles Porter, and the fee is £5 for the complete series. The elementary and theoretical part, however, can be attended at a fee of £3 13*s.* 6*d.* and the practical part for £2 2*s.* Dr. W. J Howarth and Dr. King Brown are among the lecturers for the meat inspectors' course, which lasts for two months, the fee being £4 14*s.* 6*d.*, or, including the practical part of the sanitary officers' course, £5 5*s.* Among the lecturers for the health visitors' course are Dr. J. A. H. Brincker, Dr. G. F Buchan, Dr. R. V. Clark, Dr. L. Fairfield, Dr. A. Greenwood Dr. A. B. Kingsford, Dr. E. F. Palgrave, Dr. Charles Porter Dr. Eric Pritchard, Dr. M. G. Thackrah, and Miss K. M Vaughan. The fee for the complete course, which lasts for two months, is £5 5*s.*, or for the first half, dealing with hygiene and sanitation, personal and general, £3 13*s.* 6*d.*, and the second half, dealing with the special care of the mother and child, £2 2*s.*

Dr. S. R. Alexander, who has continuously ccupied the civic chair at Faversham for the past ten ears, has been admitted to the freedom of the borough.

The Lettsomian lectures of the Medical Society f London are to be delivered by Dr. Herbert Spencer, at 1, Chandos-street, London, W., on Feb. 2nd and 16th and March 1st, at 9 P.M. Dr. Spencer has chosen as his subject he Tumours Complicating Pregnancy, Labour, and the Puerperium. Sir D'Arcy Power's annual oration on May 10th will be on "The Rev. John Ward and Medicine."

Royal Institution.—On Tuesday next (Jan. 27th), t 3 o'clock, Professor G. Elliot Smith begins a course of hree lectures at the Royal Institution on the Evolution of Man and the Early History of Civilisation. On Saturday, an. 31st, Sir Frank Watson Dyson, the Astronomer Royal, delivers the first of three lectures on the Astronomical Evidence bearing on Einstein's Theory of Gravitation; and on Thursday, Feb. 5th, Professor A. E. Conrady commences a course of two lectures on Recent Progress in Applied Optics. The Friday evening discourse on Jan. 30th will be delivered by Mr. S. G. Brown on the Gyrostatic Compass, and on Feb. 6th by Sir Walter Raleigh on Landor and the Classic Manner.

Speeding up our Home Spas.—The Harrogate Corporation announce that they have recently appointed a pathologist and bacteriologist as a consultative authority on all that appertains to the healing value of the waters, and they have also secured the services of an analytical chemist on the baths' staff, with the view of keeping the numerous mineral waters of this well known watering-place under constant scientific supervision. This policy is to be welcomed as promising to reduce the empiricisms of balneo-therapeutic practice.

The Cremation Movement.—Since the establishment of the Woking Crematorium in 1885 the number of bodies cremated has increased every year. 1795 cremations took place in 1918, and 2031 in 1919. According to the Cremation Society of England there are over 70 crematoriums in the United States, where the number of incinerations now exceeds 20,000 per annum. The society points out that no increase has been made in the pre-war charge of five guineas for incineration in London and at the majority of the provincial crematoriums, and that apart from the æsthetic and sanitary advantages of cremation, its economic advantage in saving valuable land for other purposes is also of importance to the community. Life-membership of the Cremation Society can be obtained on payment of the sum of £5 5*s*., and entitles the member to free incineration at any crematorium in Great Britain.

Donations and Bequests.—Dame Amy Fanny Tate, widow of the late Sir Henry Tate, has given, among other bequests, £1000 each to Charing Cross Hospital; the Middlesex Hospital, Cancer Ward; the Hahnemann Convalescent Home, Bournemouth; and the Homœopathic Convalescent Home, Eastbourne; £3000 to the British Home for Incurables, Streatham; £4000 to the Queen Victoria Jubilee Institution for Nurses; £500 to the Brixton Nursing Association, Tulse-hill; £300 to the Baldwin Brown Convalescent Home, Herne Bay; £1000 to the Grand Priory of the Order of the Hospital of St. John of Jerusalem; £100 each to the head nurse of the Sir Henry Tate Memorial Home, Tulse-hill, and the other nurses there; £500 to the executors for the doctors, nurses, and attendants at her last illness.—Mr. J. C. Gould, M.P., has given £10,000 to the Cardiff Hospital.—The late Miss R. J. Horlock, of Clifton, Bristol, bequeathed £1000 to the Bristol Royal Hospital for Children to endow a cot.

Health of Birmingham.—The report of Dr. J. Robertson, the medical officer of health, shows that public health in the year 1919 was better than in the preceding year. The birth-rate was still low, being only 20·7 per 1000 as compared with 27·3 in 1913, but higher than in 1917 or 1918. The death-rate was the second lowest ever recorded in Birmingham, this notwithstanding the severe epidemic of influenza. A death-rate of 13·0 is exceedingly low, being 2·2 better than in 1918, and only second to 12·6 recorded in 1917. Infant mortality showed a great improvement. The rate fell to 85 per 1000 births, much lower than in any previous year, and it is gratifying to know that for many years the rate has steadily declined. The incidence of diarrhœa and enteritis was the lowest ever registered in the city, and there were fewer cases of pulmonary tuberculosis reported last year than in any year since 1910. There is no doubt that in Birmingham tuberculosis is showing definite signs of decline, and this, as also the lower infant mortality, is to be attributed to the work of the different agencies employed by the Public Health Committee. The number of cases of pulmonary tuberculosis notified was 2609 as compared with 2905 in 1918 and 3388 in 1916.

Hospital Problems in Birmingham: An Address by Sir Bertrand Dawson.—Hospital matters are attracting much attention in Birmingham. At the end of 1918 practically every hospital found itself with a heavy deficiency. The General Hospital, for example, spent £18,268 more than its income from all sources; the Queen's Hospital, £6113; the General Dispensary, £3539; the Children's Hospital, £3470; and the Women's Hospital, £4663. The balance-sheets for 1919 are not yet published, but it is known that the total deficiency for all the hospitals will approach £50,000. An increase in annual income of this amount will be necessary to carry on the work upon its pre-war basis, but much greater demands are now made upon hospital accommodation. Compared with other towns Birmingham is badly placed in the matter of hospital beds. Whereas Manchester has 2·30 beds per 1000 of the population, Newcastle 2·26, Bristol 2·13, and Wolverhampton 2·12 beds, Birmingham has only 1·14 beds. At least 1000 new beds are required to meet present requirements. There is also great need for new convalescent homes, which would economise the beds in hospital wards. Recently there was formed a hospital council; through its activities overlapping is avoided and the expenses of administration reduced to a minimum.

On Jan. 15th Sir Bertrand Dawson addressed a large meeting of the Birmingham branch of the British Medical Association upon the future of voluntary hospitals. Laymen interested in hospital management were present. Sir Bertrand Dawson pointed out that the proportion of the community needing hospital treatment in the event of sickness was steadily increasing owing to the cost and complexity of modern treatment and the difficulties of domestic service. Not only were our hospitals inadequate in numbers, but they were not performing the right functions. They were called upon to do too much work and the wrong kind of work. In the future hospitals must be more widely distributed and graded. First should come the primary hospitals, set up in both urban and rural areas, where patients would be referred for further treatment, under the care of their own doctors. Nothing was more important than to give doctors the equipment for good work, and that could only come when they had access to institutions for such patients as required the help, organisation, and equipment of a hospital. The central hospitals should be a court of appeal. To them patients would go because their cases demanded more skill and better equipment than could be obtained in the local hospitals, or because they could serve the cause of medical education. At accessory hospitals—e.g., adapted Poor-law infirmaries—there could be treated cases which were not necessarily of great clinical interest, but which were of enormous importance from the economic point of view. Many cases, such as fistulæ, piles, and septic hands could not now be admitted, owing to the fact that beds were required for major operations. From an economic standpoint this was disastrous. From the educational point of view the work of the different hospitals should be coördinated so that they could widen the field for their students. They could in these accessory hospitals give the students the opportunity of instruction in those diseases which the great majority of them needed most when they went into practice. One of the pressing needs for years had been the establishment of a consultants' service under the Insurance Act. That would necessitate fabric, equipment, and clinics. From present evidence it seemed clear that any new hospitals would have to be maintained by public authority. The voluntary hospitals should aim at maintaining their traditions and acquiesce in peaceful penetration by the State rather than absorption. He was sure it would be a bad thing for the community if absorption took place. If the whole cost of curative treatment was provided free it would impose a very great burden on the State. Experience showed that patients did not object to paying. In the primary hospitals there might be a standard rate for public and private wards, which would include the whole of the hospital equipment, nursing, and maintenance, but not medical attendance. For the central hospitals there could also be a standard rate of admission to the public wards. This would include medical treatment, because the patient would have passed from the care of his own doctor to that of the consultant's.

The late Mr. J. T. Chamberlain.—James Thomas Chamberlain, of the Manor House, Great Shelford, near Cambridge, who died on Dec. 26th, 1919, had retired over 24 years ago after 10 years of practice in Nottinghamshire, removing at first to Harston, near Cambridge, and thence to Great Shelford. He was born on March 15th, 1856, in Leicestershire, and qualified L.R.C.P. & S. Edin., 1886, and L.F.P.S. Glasg. in the same year. He was a medallist in midwifery and diseases of women and children. He had done much quiet but effective work in the village where he resided, and was one of the trustees of the Shelford Charities and a guarantor of the Shelford Nursing Institution. He leaves a widow to mourn her loss.

THE King has appointed Colonel A. L. A. Webb, C.B., C.M.G., R.A.M.C., and Surgeon Vice-Admiral Sir William Henry Norman, K.C.B., Knights of Grace of the Order of St. John of Jerusalem in England.

Bretby Hall, Burton-on-Trent, formerly the seat of the Earl of Carnarvon, has just been bought by the Derbyshire County Council for use as a sanatorium for tuberculous cases. It stands in a park of 700 acres, of which some 440 acres, mostly of sandy gravel, have been obtained.

STAMMERING IN SCHOOL CHILDREN IN BATH.—On the recommendation of the school medical officer for Bath, a class for stammering children, in which the Berguand method may be used, is to be formed.

HOSPITAL SUNDAY FUND AT PLYMOUTH.—As a result of the Hospital Sunday collection in Plymouth, which was observed in October last, the sum of £750 has been received for the South Devon and East Cornwall Hospital, compared with £627 in 1918.

PRESENTATION TO A MEDICAL MAN.—Dr. A. E. Larking, J.P., who has retired after 13 years' residence in Buckingham, was recently presented by over 700 patients and friends with an album containing their names, together with an illuminated address and £50.

DIDWORTHY SANATORIUM, DARTMOOR.—This institution has received a grant of £250 from the King Edward's Hospital Fund for London, in consideration of which ten beds will be reserved for the use of certain London hospitals during 1920.

A LONG APPOINTMENT.—At the last meeting of the Liskeard (Cornwall) board of guardians Mr. W. Nettle, J.P., resigned the post of medical officer to the workhouse and No. 1 district, after nearly 46 years' service. The resignation was accepted with regret, and several of the guardians alluded to Mr. Nettle's valuable services.

DEATH OF DR. A. N. LEDINGHAM.—Alexander Napier Ledingham, who died at his residence in Bayswater from heart failure on Jan. 13th, studied medicine at Glasgow University and at University College, London. He graduated M.B., C.M. at Glasgow in 1880 and five years later the F.R.F.P.S. Glasgow. In 1891 he obtained the D.P.H. of the English Conjoint Board. Dr. Ledingham was surgeon to the British India Steam Navigation Company and superintendent of the Queensland Government Emigration Service. Formerly he was resident surgeon to the Glasgow Maternity Hospital and to the Glasgow Royal Infirmary.

NURSES REGISTRATION (SCOTLAND) ACT, 1919.—The Scottish Board of Health are taking steps towards the constitution of the General Nursing Council for Scotland established by the Nursing Registration (Scotland) Act, 1919. On the first constitution of the Council 13 of the 15 persons composing the council are to be appointed by the Scottish Board of Health. Four are to be appointed after consultation with persons and bodies having special knowledge and experience of training schools for nurses, of the work of matrons of hospitals, of general and special nursing services and of general and special medical practice, and nine of the persons to be appointed by the Board of Health must be, or must have been at some time, nurses actually engaged in rendering services in direct connexion with the nursing of the sick. The Board, anxious that the new council should be representative, invite suggestions for membership of the council, but all recommendations should be accompanied by a statement of the special qualifications and experience of the persons suggested.

THE LATE DR. H. W. DARRELL.—By the death of Harrington Wyndham Darrell, who died on Jan. 10th from pleurisy and pneumonia at the age of 56, a well-known figure is removed from Norwich medical circles. He was born at Devonshire, Bermuda, and educated at the University of Toronto, where he obtained his M.D. degree. He also studied at the London Hospital, qualified as L.R.C.P. Lond., and settled in Norwich about 35 years ago. Dr. Darrell built up a large practice, which included many panel patients. He held the appointments of Poor-law medical officer, and surgeon-accoucheur to the Norwich Lying-in Charity. A Conservative and a keen tariff reformer, he was for many years a member of the Norwich City Council. He was a recognised expert on horses, his stud of trotting horses and ponies being well known locally; he was also a member of the Norfolk and Norwich Kennel Club, and possessed a variety of large and small dogs. Ornithology was also one of his hobbies, and his special study of foreign birds brought him some general recognition as an authority on this subject. As might reasonably be expected, a man of such varied interests was very popular, and his funeral was largely attended.

The Services.

ARMY MEDICAL SERVICE.

Major-Gen. Sir H. N. Thompson, K.C.M.G., is placed on the half-pay list.

Temp. Col. C. M. Wenyon, C.M.G., relinquishes his commission and retains the rank of Colonel.

Col. F. W. Begbie, C.B.E., retires on retired pay.

ROYAL ARMY MEDICAL CORPS.

The undermentioned relinquish the acting rank of Lieutenant-Colonel: Majors J. H. R. Winder and R. W. D. Leslie; Capt. E. W. Wade; Temp. Capt. R. Jamison (on ceasing to be specially employed).

Capts. W. K. Campbell, J. F. Bourke, A. Jackson, and Temp. Capts. R. Nichol, J. Porter, W. Brown relinquish the acting rank of Major.

Temp. Capt. (acting Major) D. O. Riddel relinquishes the pay and allowances of his acting rank.

J. A. Martin and J. A. Cowan to be temporary Captains.

Temporary Lieutenants to be temporary Captains: P. Johnson, W. L. Young, J. H. Rodgers, C. K. T. Hewson, P. P. Galea, F. C. S. Bradbury, H. G. Watters, H. H. McClelland.

Officers relinquishing their commissions:—Temp. Major F. C. Purser (and retains the rank of Major); Bt. Major S. P. Hodkinson (retains the Brevet rank of Major); Temp. Capt. A. Peden. Temporary Captains granted the rank of Major: G. Jackson, S. S. Dunn, T. M. Bellew, W. H. Alderton, P. J. Lane, W. Gemmill, J. G. Duncanson, R. MacDonald. Temporary Captains retaining the rank of Captain: J. P. McGreehin, R. W. L. Todd, P. C. Cole, C. L. Stewart, B. E. Laurence, B. Dunlop, A. Davidson, W. H. Bush, A. J. Dempsey, J. Russell, J. J. Dowdall, M. R. V. Ford, L. T. Stewart, R. M. Wilson, W. K. Connell, J. McPolin, I. S. James, S. J. Cowell, C. R. Denny, E. Gordon, A. Dick, A. Scott, E. D. Wortley, P. Davies, J. A. D. Radcliffe, H. J. Gater, S. P. Moore, G. O. Connell, L. C. Johnston, R. C. Maclachlan, C. N. Coad, A. F. Flower, W. Hornsby.

SPECIAL RESERVE OF OFFICERS.

Capt. W. Donald relinquishes the acting rank of Major.

TERRITORIAL FORCE.

Capts. (acting Majors) M. Coplans and E. A. Houchin relinquish the acting rank of Major on ceasing to be specially employed.

1st London Sanitary Company: Lieut. F. C. Cook to be Captain.

2nd London Sanitary Company: Lieut. S. Shaw to be Captain.

ROYAL AIR FORCE.

Medical Branch.—J. D. Keir (Surgeon Commander, R.N.) is granted a temporary commission as Lieutenant-Colonel.

Capts. H. Munro, J. A. Johnson, and S. A. Nield-Faulkner are transferred to the unemployed list.

H. J. Swan (late Flying Officer, R.A.F.) is granted a temporary commission as Flight Lieutenant.

THE HONOURS LIST.

The following awards for war services are announced:—

C.B.E.—Temp. Lt.-Col. R. Row, I.M.S.; Capt. D. R. R. Singh. I.M.S.; Mr. C. H. Elmes, O.B.E., officiating Health Officer, Port of Calcutta, Bengal.

O.B.E.—Miss R. Balmer, Hon. Capt. R.A.F. Med. Serv.; Flight-Lieut. R. L. Roe, R.A.M.C.; Mr. C. H. Lincoln, M.B.E., Asst. Surg., Ind. Med. Dept., acting Consul for Arabistan, Persian Gulf.

M.B.E.—Khan Bahadur Mir Diwan Ali, Civil Surg., Multan, Punjab; Mr. G. N. Coombes, Chief Med. and Sanit. Officer of the Cochin State, Madras; Mr. J. D. O'Donnell, Chief Med. Officer, Kolar Gold Field, Mysore.

BROUGHT TO NOTICE.

The names of the following (all of the R.A.M.C. except where otherwise stated) have been brought to the notice of the Secretary of State for War for valuable services rendered on hospital ships during the war:—

Capt. I. M. Byers; Temp. Capt. (acting Maj.) W. A. Clayton; Maj. E. L. D. Dewdney (T.F.); Maj. C. L. Dunn, I.M.S.; Temp. Capt. H. B. Emerson; Temp. Capt. J. H. Glover; Capt. J. W. Grice; Temp. Capt. W. R. G. Hamilton; Temp. Maj. J. G. Heath; Temp. Capt. T. Heywood; Temp. Capt. W. P. Jones; Temp. Capt. H. A. Lane; Temp. Capt. J. M. Lazenby; Temp. Capt. G. W. P. Maitland; Temp. Capt. (acting Maj.) H. McIntyre; Temp. Maj. R. T. Meadows, D.S.O.; Temp. Capt. (acting Maj.) H. H. O'Heffernan; Surg.-Maj. B. Pares, C.M.G., D.S.O., R.H. Gds.; Lt. (acting Capt.) E. H. Rainey; Temp. Maj. P. J. A. Seccombe; Temp. Capt. R. E. Smith; Temp. Maj. T. Walcot; Temp. Maj. A. W. Wilcox; Lt.-Col. H. A. Williams, D.S.O., I.M.S.

The names of the following (all of the R.A.M.C. except where otherwise stated), brought to notice for distinguished

nd gallant services and devotion to duty, are to be added to he lists already published dealing with the spheres of perations detailed:—

France.—Temp. Capt. H. Body; Col. N. Faichnie; Maj. J. H. urley; Capt. D. C. Scott.

Egypt.—Temp. Capt. W. I. Adams; Capt. (acting Lt.-Col.) J. lackwood; Lt. (temp. Capt.) W. M. Cameron; Temp. Capt. T. L. lark; Temp. Capt. W. E. R. Dimond; Lt.-Col. (acting Col.) C. arner, C.B.E.; Temp. Capt. F. W. Grant; Capt. D. R. Hennessy; t.-Col. P. S. Lelean, C.B.; Temp. Capt. F. A. L'Estrange; Capt. . H. Maingot; Capt. S. A. Mann; Temp. Capt. T. D. Miller; Temp. apt. G. C. Ramsay; Capt. P. W. Ransom; Capt. (acting Maj.) A. E. ichmond; Capt. P. P. J. Stewart; Temp. Capt. S. M. Vassallo; emp. Capt. M. J. T. Wallis; Capt. C. H. Welsh; Capt. . B. Willan; Temp. Capt. H. G. E. Williams. *Austr. .M.C.*—Maj. (temp. Lt.-Col.). J. R. Mc.N. Beith; Lt.-Col. . B. Blackburn, O.B.E.; Maj. (temp. Lt.-Col.) M. W. Cave; Capt. . A. Comins; Capt. C. R. Hodgson; Maj. E. K. Parry, M.C.; Maj. . Sutton; Capt. W. G. H. Tregear. *New Zealand M.C.*—Lt.-Col. . H. Walton. *I.M.S.*—Capt. A. W. Duncan; Capt. (acting Maj.) . L. Duncan; Temp. Capt. C. M. Ganapathy; Temp. Lt. G. A. ildreth; Capt. (temp. Maj.) R. F. D. MacGregor, M.C.; Maj. cting Lt.-Col.) J. Mc. A. Macmillan; Capt. A. Seddon; Temp. t. D. S. Otto.

Italy.—Temp. Capt. (acting Maj.) J. C. L. Day; Temp. Capt. acting Maj.) H. E. Gamden; Lt. W. R. McLinden.

Mediterranean Lines of Communication.—Col. J. C. B. Statham, .M.G., A.M.S.

Mesopotamia.—Temp. Capt. G. A. Back; Temp. Capt. B. E. A. att; Capt. A. B. Black; Temp. Capt. N. G. Braham, M.C.; Capt. . Brawn; Capt. (acting Maj.) E. Butler; Temp. Capt. L. D. allender; Temp. Capt. A. L. Candler; Capt. (acting Maj.) J. W. annon; Capt. R. Colley; Capt. W. H. Dye; Temp. Capt. H. Findlay; apt. (acting Maj.) J. F. Grant; Temp. Capt. N. Gray; Capt. (temp. aj.) T. J. Hallinan; Capt. J. S. Hopwood; Lt. W. M. Jones; apt. J. LeM. Kneebone; Lt. L. K. Ledger; Temp. Capt. J. N. Lyons; apt. (acting Maj.) C. E. W. McDonald; Temp. Capt. M. D. ackenzie; Temp. Capt. (acting Lt.-Col.) T. H. Martin; Capt. C. K. owll; Lt.-Col. A. R. O'Flaherty; Capt. A. B. Preston; Capt. (temp. aj.) H. G. Robertson; Capt. R. Rodger; Temp. Capt. B. T. aunders; Temp. Capt. R. G. Smith; Temp. Capt. P. Talbot; Temp. t. W. B. Vaile; Capt. (acting Maj.) A. Wilson; Temp. Capt. G. S. Woodnan. *I.M.S.*—Lt.-Col. A. E. Berry; Maj. (acting Lt.-Col.) E. W. C. radfield, O.B.E.; Capt. (acting Maj.) R. A. Chambers; Temp. apt. B. R. Chandorkar; Capt. (acting Maj.) P. D. Chopra; Capt. . C. De; Temp. Capt. S. B. Gothaskar; Lt.-Col. (temp. Col.) E. V. ugo, C.M.G.; Capt. (acting Maj.) E. W. O'G. Kirwan; Temp. Capt. . G. Mukharji; Maj. (acting Lt.-Col.) M. J. Quirke.

Salonika.—Capt. L. B. Clarke; Temp. Capt. W. D. Cruickshank; emp. Capt. J. R. Davies; Capt. G. Hardwike; Capt. (acting aj.) I. Jones; Capt. P. Seymour-Price; Capt. C. G. Skinner; apt. (acting Maj.) D. G. Stoute; Temp. Capt. A. C. Sturrock.

The names of the following have been brought to notice or gallant and distinguished services rendered at Aden uring the period from Sept. 1st to Dec. 31st, 1918:—

Lt.-Col. T. H. Foulkes, I.M.S.; Maj. (temp. Lt.-Col.) I. M. Macrae.

TERRITORIAL DECORATION.

The King has conferred the Territorial Decoration upon he undermentioned officers:—

Army Medical Service.—Col. P. C. Burgess.

Royal Army Medical Corps.—Capt. (acting Major) A. L. Whitehead, 2nd Northern General Hospital; Capt. G. J. R. Lowe, th Northern General Hospital; Lieut.-Col. A. G. Hay, 3rd Scottish General Hospital; Capt. and Brevet Major K. W. Monsarrat, 1st Western General Hospital; Lieut.-Col. F. E. Fremantle, General List; Major W. D. Watson, 1st East Anglian Field Ambulance; Major A. E. Kidd, 3rd Highland Field Ambulance; Major J. Wood, 1st West Lancs Field Ambulance; Capt. F. W. K. Tough, 3rd West Lancs Field Ambulance; Major W. A. Burns, 2nd Lowland Field Ambulance; Major J. H. Dixon, 5th London Field Ambulance; Lieut.-Col. J. Allison, attached Northumbrian Yeomanry; Major P. McK. Terry, attached Wessex Division Ammunition Column, R.F.A.; Lieut.-Col. F. W. Gibbon, attached Tyne Electrical Engineers; Major (acting Lieut.-Col.) J. Scott, attached 5th Battalion, Royal Scots; Major W. Haig, attached 6th Battalion, Royal Highlanders; Major J. Middleton, attached 5th Battalion, Gordon Highlanders.

THE LATE DR. J. W. HEMBROUGH.—John William Hembrough, who died on Jan. 13th after undergoing an operation, had been medical officer of health for Northumberland for the past 26 years. A native of Lincoln, he studied medicine at St. Bartholomew's Hospital, London, where he held several resident posts. He qualified L.S.A. in 1865 and M.R.C.S. Eng. in the following year, and was health officer to the Tynemouth rural sanitary authority before becoming county officer, later obtaining the M.D. Durh. and the D.P.H.

SUDDEN DEATH OF MR. C. M. BERNAYS.—Charles Murchison Bernays, who qualified L.R.C.P. Lond., M.R.C.S. Eng. in 1906, was found dead on Jan. 6th at the Royal Victoria Hospital, Dover, where he was house surgeon, a few minutes after attending a casualty case. After qualifying, he started practice at Shirley, Birmingham, but joined the Royal Army Medical Corps on the outbreak of war, and served in a front line clearing station in France from 1914 to 1917, where in August of that year he was badly gassed. His death was due to hæmorrhage as a result of this gassing.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than* 9 *o'clock on the Thursday morning of each week, such information for gratuitous publication.*

CORFIELD, C. R., L.M.S.S.A., has been appointed Second Anæsthetist to the Northern Hospital for Women and Children, Manchester.

SALMOND, R. W. A., M.D., Ch.M., Honorary Radiologist to University College Hospital, and Lecturer in Radiology at the Medical School.

VLIELAND, C. J., M.D. Durh., M.R.C.S., L.S.A., Medical Officer of the New Clinic for the Treatment of Venereal Disease at the Royal Devon and Exeter Hospital.

University of Cambridge: PALMER, W. G., of St. John's College, Demonstrator of Chemistry; THACKER, C. R. A., of Sidney Sussex College, Demonstrator of Physiology; and SWAN, M. B. R., of Gonville and Caius College, Demonstrator of Pathology.

Certifying Surgeons under the Factory and Workshop Acts: SELLORS, T. B., M.D. Durh. (Essex), MACCARTHY, J. T. (Coolrain), PRETTY, K., M.B. Camb. (Ipswich), DOUGLAS, J. H., M.D. Glasg. (Whithorn).

Vacancies.

For further information refer to the advertisement columns.

Barnsley, Beckett Hospital.—H.S. £200.
Bedford County Hospital.—H.S. and H.P. £175 and £150 respectively.
Belgrave Hospital for Children, Clapham-road, S.W.—Asst. P.
Birkenhead Borough Hospital.—Two Hon. Asst. M.O.'s.
Birmingham City Mental Hospital, Rubery Hill, near Birmingham.—First and Second Asst. M.O.'s. £500 and £400.
Birmingham, City Fever Hospital, Little Bromwich.—Asst. M.O. £300.
Birmingham General Hospital.—H.P., Obstet. H.S., and H.S. £100. Clin. Path. £600.
Bradford City Education Committee, Medical Inspection of School Children.—Asst. Sch. M.O. £600.
Bradford Union, St. Luke's Hospital.—Asst. Res. M.O. £400.
Bristol, Beach House Estate Sanatorium.—Res. Supt. M.O. £800.
Bristol General Hospital.—Senr. R.M.O. £300.
British Guiana.—Asst. M.O. £400.
Camberwell Borough.—Asst. M.O.H. £550.
Carlisle, Cumberland and Westmorland Mental Hospital, Garlands.—Jun. Asst. M.O. £350.
Chartham, near Canterbury, Kent County Mental Hospital.—Jun. Asst. Third M.O. £300.
Colchester, Essex County Hospital.—H.P. £200.
Cornwall County Council, Truro Venereal Clinics.—Part-time M.O.'s.
Darlington General Hospital.—H.S. £250.
Derbyshire Education Committee.—Sch. M.O. £500.
Dorchester, Dorset County Council Education Committee.—School Dentists. £400.
Dover, Royal Victoria Hospital.—H.S. £180.
Dreadnought Hospital, Greenwich.—H.S. £50.
Dudley County Borough.—M.O.H. and Sch. M.O. £800.
Dudley, Guest Hospital and Eye Infirmary.—Vacancy on Hon. Surg. Staff. Also two Hon. P.'s.
East Suffolk County Education Committee.—Dentist £400.
Elizabeth Garrett Anderson Hospital, Euston-road.—Jun. Asst. P., Path., Asst. Path. Also Clin. Asst. £1 1s. per attendance.
Farringdon General Dispensary, 17, Bartlett's-buildings, Holborn Circus, E.C.—Hon. P.
Gilbert and Ellice Islands Colony and British Solomon Islands Protectorate.—Sen. M.O.'s. £600 each.
Gold Coast and Sierra Leone.—Dent. S. £500.
Hospital for Sick Children, Great Ormond-street, London, W.C.—H.S. £50.
Kincardine Education Authority.—Asst. Sch. M.O. £450
Lancaster County Asylum.—Asst. M.O. £300.
Leamington Spa, Borough of.—M.O.H. £650.
Leasowe, Cheshire, Hospital for Children.—Junr. M.O. £200.
Leeds Infirmary, Indoor Institutions, Beckett-street.—Second Asst. M.O. £300.
Leeds Public Dispensary.—Hon. Radiologist.
Lewes, East Sussex County Council Education Committee.—Jun. Asst. Sch. M.O. £450.
Lincoln County Hospital.—Jun. H.S. £150.
Lindsey County Council.—Asst. Tuberc. O. and Asst. Sch. M.O. £450.
Liverpool Stanley Hospital.—H.P. and S. £150 each.
London County Council Mental Hospitals Service.—Fifth Asst. M.O.'s. £300.
London Hospital Medical College, Mile End, E.—Lecturer on Neuroses and Psycho-Neuroses.
Manchester, Ancoats Hospital.—H.P. £150.
Manchester Children's Hospital, Pendlebury, near Manchester.—Res. M.O. £150. Asst. S. £50.
Margate, Royal Sea-Bathing Hospital for Surgical Tuberculosis.—Res. S. £200.
Metropolitan Ear, Nose, and Throat Hospital, 2, Fitzroy-square, W.—Clin. Assts.
Metropolitan Hospital, Kingsland-road, E.—Asst. P.
Middlesex County Council.—Temp. Tuberc. M.O. £600.
Miller General Hospital for South-East London, Greenwich-road, S.E.—Res. Cas. O. Also H.S. £100.
Newcastle-upon-Tyne, Hospital for Sick Children.—Junior Res. M.O. £200.
Newcastle-upon-Tyne, Royal Victoria Infirmary.—Specialist M.O. £500. Two Surg. Specialists. £125. Jwo Junr. M.O.'s. £450 and £218 8s. Female Junr. M.O. £327 10s.

New Zealand, Auckland Hospital.—Bact. and Path. £900.
Norwich City.—Asst. M.O.H. £300.
Nottingham Children's Hospital.—Female Res. H.S. £200.
Nottingham City Education Committee.—Jun. Asst. Sch. M.O. £500.
Nottingham General Hospital.—H.S. £150.
Oldham County Borough.—Asst. M.O. £400.
Oxford, Radcliffe Infirmary and County Hospital.—H.P. Cas. H.S. £200.
Paddington Green Children's Hospital, London, W.—S. to Eye Dept., P. to Skin Dept., and P. to Out-patients.
Peterborough Infirmary.—H.S. £150.
Plymouth, South Devon and East Cornwall Hospital.—H.S. £200. H.P. £140.
Prince of Wales's General Hospital, Tottenham, N.—Hon. Asst. P., Hon. P. to Children's Dept., and Clin. Assts.
Queen's Hospital for Children, Hackney-road, Bethnal Green, E.—Clin. Assts.
Reeth Union and Rural District Council, Yorkshire.—M.O.H. £170.
Royal Free Hospital, Gray's Inn-road, W.C.—Asst. M.O.'s in Venereal Diseases (Female) Dept. £250 and £150 respectively.
Royal Waterloo Hospital for Children and Women, S.E.—Hon. Ophth. S. and Hon. S. to Out-patients.
St. Bartholomew's Hospital.—Asst. Physician-Accoucheur.
St. Mary's Hospital, Paddington.—First Asst. Pathol. £500.
St. Pancras Borough Council.—Asst. M.O. £450.
Salisbury Municipality, Rhodesia, S.A.—M.O.H. £600
Sheffield Royal Hospital.—Asst. Cas. O. £120.
South London Hospital for Women, South Side, Clapham Common, S.W.—Female Clin. Assts.
Straits Settlements.—Res. M.O. £840.
Straits Settlements and Federated Malay States.—M.O.'s.
Swansea County Borough.—Asst. M.O.'s. £600 and £500.
University of London, South Kensington.—Examiners.
Victoria Hospital for Children, Tite-street, Chelsea, S.W.—S. to Out-patients.
Wakefield, West Riding County Council.—School Oculist. £550.
Wallsend Borough.—M.O.H. £800.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Newmains, Duncannon, and at Rochdale.

Births, Marriages, and Deaths.

BIRTHS.

BIGGER.—On Jan. 16th, at a Nursing Home, the wife of Walter G. Bigger, D.S.C., M.B., B.Ch., St. Thomas's Hospital, of a daughter.

BONNEY.—On Jan. 10th, at Vicarage-gardens, Kensington, the wife of Ernest H. Bonney, M.R.C.S., L.R.C.P., of a son.

COLLINGRIDGE.—On Jan. 13th, at The Manor House, Goudhurst, Kent, the wife of W. R. Collingridge, M.R.C.S., of a daughter.

KENNEDY.—On Jan. 11th, at Wantage, Berkshire, the wife of W. D. Kennedy, M.B., of a son.

MARRIAGES.

SILLEY—BOSWELL.—On Jan. 15th, at St. Martin's Parish Church, Scarborough, Herbert Henry Silley, M.R.C.S., L.R.C.P., to Katharine Mary, eldest daughter of the late Mr. and Mrs. E. W. Boswell, of Norwich.

SUNDERLAND—SMITH.—On Jan. 15th, Reginald Henry Sunderland, M.R.C.S., L.R.C.P., of Bradford, to Grace Clarissa Smith, of Highgate, Walsall.

SWAN—KELLY.—On Dec. 10th, 1919, at the Roman Catholic Church, College-road, Malvern, by the Rev. J. Jordan, Harold J. Swan, M.B., B.Ch., of Terenure, Dublin, to Marcella Bertile Kelly, M.B., B.Ch., of Ballymote, Co. Sligo.

DEATHS.

ATKINSON.—On Jan. 14th, at his residence, Butts Park, St. Tudy, Cornwall, Charles Henry Fairbank Atkinson, O.B.E., M.R.C.S., L.R.C.P., Surgeon-Lieutenant, R.N.V.R.

CALEY.—On Jan. 15th, following an operation, Guthrie Neville Caley, M.D., M.S., of Colville House, Ealing, aged 58 years.

LEDINGHAM—On Jan. 13th, of heart failure, Alexander Napier Ledingham, M.B., C.M., F.R.F.P.S. Glasg., and D.P.H. Lond.

TURNER.—On Jan. 16th, at Stanton, Anerley, S.E., John Sidney Turner, J.P. (Kent), F.L.S., F.Z.S., M.R.C.S., aged 76 years.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

BOOKS, ETC., RECEIVED.

BAILLIÈRE, TINDALL, AND COX, London.
Letters of a Widowed Physician to His Daughter at Puberty, Maturity, Marriage, and Motherhood. Pp. 64. 2*s.* 6*d.*

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.
THURSDAY, Jan. 29th.—Papers:—Prof. W. Bateson: The Genetics of "Rogues" among Culinary Peas. (Pisum Sativum.)—Mr. L. T. Hogben: Studies on Synapsis. I., Oogenesis in the Hymenoptera (communicated by Prof. E. W. MacBride).—Mr. H. Onslow: On a Periodic Structure in Many Insect Scales, and the Cause of their Iridescent Colours (communicated by Prof. F. G. Hopkins).

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

Friday, Jan. 30th.

SOCIAL EVENING: The next Social Evening will be on Friday, Jan. 30th, at 8.30 P.M. Sir D'Arcy Power has kindly agreed to give a twenty minutes' talk (illustrated) on "The Fees of Our Predecessors."

The Library will be open, and Dr. Andrew Balfour, Dr. F. W. Cock, Dr. W. J. R. and Mrs. Simpson, and Dr. Jane Walker will exhibit objects of interest. Music and light refreshments. It is hoped there will be a good attendance of Fellows and their friends (including ladies), who will be cordially welcomed.

The President, Sir Humphry Rolleston, and Lady Rolleston will receive the guests at 8.30 P.M.

MEETINGS OF SECTIONS.

Monday, Jan. 26th.

ODONTOLOGY (Hon. Secretaries—G. Paton Pollitt, W. Kelsey Fry, J. Howard Mummery): at 8 P.M.
Paper:
Mr. S. F. St. J. Steadman: Dental Sepsis in Children, its Consequences and Treatment.

Tuesday, Jan. 27th.

MEDICINE (Hon. Secretaries—W. Cecil Bosanquet, J. H. Thursfield): at 5.30 P.M.
Paper:
Dr. W. H. Willcox: Typhus and Relapsing Fever in Mesopotamia and Northern Persia.
Dr. Arkwright and Dr. Ledingham will speak on the bacteriology.

Thursday, Jan. 29th.

BALNEOLOGY AND CLIMATOLOGY (Hon. Secretaries—J. Campbell McClure, C. F. Sonntag, F. G. Thomson): at 5.30 P.M.
Discussion:
On "The Merits and Defects of the British Health Resorts," to be opened by Dr. Neville Wood.

THERAPEUTICS AND PHARMACOLOGY.—Members of this Section are cordially invited to attend and to take part in the above Discussion.

Those desiring to speak are requested to send their names to Dr. C. F. Sonntag, 80a, Belsize Park-gardens, N.W. 3.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.
MONDAY, Jan. 26th.—8.30 P.M., Demonstration of Pathological and Medico-Legal Specimens by Dr. J. L. Dimond, Dr. J. Freeman, Dr. B. Spilsbury, Dr. C. E. Lakin, Dr. A. Fleming, Dr. Elsworthy, and Dr. Greenfield.

HUNTERIAN SOCIETY, at the School of Oriental Languages, Finsbury-circus, E.C.
WEDNESDAY, Jan. 28th.—9 P.M., Paper:—Dr. A. E. Gow: Treatment by Protein Shock.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.
Six Hunterian Lectures on John Hunter's Observations and Discoveries in Anatomy and Surgery (illustrated by his specimens and preparations).
MONDAY, Jan. 26th.—5 P.M., Prof. A. Keith: IV., His Contributions to Our Knowledge of the Kidneys, Bladder and Urethra, and Diseases connected with these Structures.
WEDNESDAY.—5 P.M., Prof. A. Keith: V., His Contributions to Our Knowledge of the Genital and Reproductive Systems.
FRIDAY.—5 P.M., Prof. A. Keith: VI., His Contributions to Our Knowledge of the Eye, Ear, and Nose.

UNIVERSITY OF LONDON.
Advanced Lectures in Physiology to Students of the University and others interested in the subject.
A Course of Eight Lectures on Physiologically Balanced Solutions will be given by Dr. W. L. Symes in the Physiological Laboratory of the University, South Kensington, S.W.
TUESDAY Jan. 27th.—5 P.M., Lecture I.
A Course of Eight Lectures on the Reaction of the Blood and Acidosis will be given by Dr. J. W. Trevan, at St. Bartholomew's Hospital, West Smithfield, E.C.
WEDNESDAY, Jan. 28th.—4.30 P.M., Lecture I.
A Course of Eight Lectures on the Regulation of Respiration will be given by Dr. M. S. Pembrey and Mr. J. H. Ryffel at Guy's Hospital, Borough, S.E.
THURSDAY, Jan. 29th.—4.30 P.M., Lecture IV.

LONDON HOSPITAL MEDICAL COLLEGE (UNIVERSITY OF LONDON), Mile End, E.
A Course of Instruction on the Diseases of Children, open to Post-Graduates and to Students of the Hospital. (The lectures will be illustrated by lantern slides.)
MONDAY, Jan. 26th.—9.15 A.M., Lecture III.:—Dr. Thompson: Organic and Functional Nervous Diseases, Meningitis and Mental Deficiency. (At the Anatomical Theatre.)
WEDNESDAY.—10 A.M., Clinical Demonstration:—Dr. Miller. (At the Children's Out-patient Department.)
SATURDAY.—10.15 A.M., Lecture IV., Dr. Hutchison: General Diseases. (At the Anatomical Theatre.)

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL (University of London).

A Post-Graduate Course of Lectures on Syphilis will be given by various members of the staff of King's College Hospital during the ensuing year :—

Friday, Jan 30th.—9.15 p.m., Lecture I.:—Dr. W. d'Este Emery: Pathology and Pathological Diagnosis; Methods of Collecting Material for Spirochætes and for Wassermann Reaction; Interpretation of Results.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART POST-GRADUATE COURSE, Westmoreland-street, W.

Monday, Jan. 26th.—11 a.m., Out-patients: Dr. Goodall. 2 p.m., In-patients: Dr. Moon.

Tuesday.—2 p.m., Out-patients: Dr. R. Wells. 3 p.m., In-patients: Dr. Gibbes.

Wednesday.—2 p.m., Out-patients: Dr. Moon. 5.30 p.m., Lecture :—Dr. Price: The Pulse in Diagnosis (1).

Thursday.—10 a.m., In-patients: Dr. Hamill: 2 p.m., Out-patients: Dr. Price.

Friday.—2 p.m., Out-patients: Dr. Gibbes. 2.30 p.m., In-patients: Dr. Wells.

Saturday.—10.30 a.m., In-patients: Dr. Hamill.

ROYAL INSTITUTE OF PUBLIC HEALTH, in the Lecture Hall of the Institute, 37, Russell-square, W.C.

Special Course of Lectures and Demonstrations on Tuberculosis for Medical Men and Women qualifying to become Tuberculosis Officers, General Practitioners, and others. Bacteriological Demonstrations will be given in the Laboratories of the Institute, and visits arranged to Sanatoriums, Tuberculosis Dispensaries, &c.

Thursday, Jan. 29th.—5 p.m., Lecture III.:—Dr. O. May: Tuberculosis in Relation to Life Assurance.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

Tuesday, Jan. 27th.—2 p.m., Demonstration :—Dr. J. Metcalfe: The X Ray Treatment of Diseases of the Thyroid Gland. 4.30 p.m., Lantern Lecture :—Lieut.-Col. R. H. Elliot: The Treatment of Glaucoma.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, W.C. 1.

MEDICAL SCHOOL.

Monday, Jan. 26th.—2–3.30 p.m., Out-patient Clinic: Dr. Collier. 3.30 p.m., Dr. S. A. Kinnier Wilson: Examination of Nervous System and Interpretation of Physical Signs. III.

Tuesday, Jan. 27th.—2–3.30 p.m., Out-patient Clinic: Dr. Grainger Stewart. 3.30 p.m., Ward Cases: Dr. Risien Russell.

Wednesday, Jan. 28th.—2 p.m., Mr. Scott: Auditory Vertigo and Forced Movements. 3.30 p.m., Dr. Greenfield: Pathological Demonstration.

Thursday, Jan. 29th.—2–3.30 p.m., Out-patient Clinic: Dr. Farquhar Buzzard. 3.30 p.m., Dr. S. A. Kinnier Wilson: Examination of Nervous System and Interpretation of Physical Signs. IV.

Friday, Jan. 30th.—2–3.30 p.m., Out-patient Clinic: Dr. Gordon Holmes. 3.30 p.m., Ward Cases: Dr. Tooth.

Saturday, Jan. 31st.—9 a.m., Surgical Operations.

Fee for Post-Graduate Course £7 7*s*. C. M. Hinds Howell, Dean.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

Friday, Jan. 23rd.—5 p.m., Special Lecture :—Prof. W. M. Bayliss: Acidosis.

Saturday.—10 a.m., Dr. A. Saunders: Medical Diseases of Children.

Monday.—5 p.m., Mr. Addison: Club Foot.

Tuesday.—5 p.m., Mr. Banks Davis: Common Affections of the Middle Ear—Treatment.

Wednesday.—5 p.m., Mr. Souttar: Clinical Surgery.

Thursday.—5 p.m., Dr. G. Stewart: Encephalitis Lethargica.

Friday.—5 p.m., Special Lecture :—Mr. MacMahon: The Treatment of Functional and Organic Affections of Voice and Speech.

ROYAL COLONIAL INSTITUTE, at the Central Hall, Westminster, S.W.

Tuesday, Jan. 27th.—3.30 p.m., Paper :—Dr. L. W. Sambon: Tropical and Sub-Tropical Diseases.

ROYAL INSTITUTION OF GREAT BRITAIN, Albemarle-street, Piccadilly, W.

Tuesday, Jan. 27th.—3 p.m., Lecture :—Prof. G. E. Smith: The Evolution of Man and the Early History of Civilisation. I., Man's Origin.

UNIVERSITY OF SHEFFIELD—FACULTY OF MEDICINE POST-GRADUATE DEMONSTRATIONS, at the Sheffield Royal Hospital.

Monday, Jan. 26th.—3.30 p.m., Dr. Nutt: Localisation of Foreign Bodies.

Tuesday.—4 p.m., Dr. Hay: Methods of Examination of Eye (continued).

Wednesday.—3.30 p.m., Dr. Wilkinson: Enlarged Tonsils and Adenoids.

Thursday.—3.30 p.m., Dr. Skinner: Urticaria: Purpura, &c.

Friday.—4 p.m., Dr. Hay: Ocular Sequelæ of General Diseases.

UNIVERSITY OF BIRMINGHAM—FACULTY OF MEDICINE, in the Anatomical Theatre, Edmund-street, Birmingham.

Post-Graduate Course of Lectures on Venereal Disease :—

Wednesday, Jan. 28th.—4.15 p.m., Mr. B. Ward: Gonorrhœa in the Male. (Lecture II.)

MANCHESTER ROYAL INFIRMARY POST-GRADUATE CLINIC.

Tuesday, Jan. 27th.—4.30 p.m., Lecture :—Mr. W. H. Hey: Surgical Treatment of Incurable Cancer.

SALFORD ROYAL HOSPITAL and ANCOATS HOSPITAL POST-GRADUATE DEMONSTRATIONS, at the two Hospitals alternately.

Thursday, Jan. 29th.—4.30 p.m., Mr. Douglas: Clinical Demonstration. (At Ancoats Hospital.)

Notes, Short Comments, and Answers to Correspondents.

PUBLIC HEALTH IN BOMBAY, 1918.

The population of Bombay at the Census taken in 1911 was found to be 979,445, and on this figure the ratios of sickness and mortality are still calculated, but Dr. J. A. Turner, the then health officer, reports that since that year "the city's population has vastly increased; besides the natural increase, we have to take into account the increase due to adventitious causes, which may be roughly put down at 200,000 to 300,000." The ratios of disease incidence and mortality require, therefore, to be materially modified. "The outstanding feature of the year was a series of epidemics, which followed one another in quick succession, lasting altogether for over 39 weeks, and were responsible for an appalling increase in mortality."

Birth and Death Ratios.

The birth-rate is reckoned as 22·18 per 1000 and the general death-rate at 59·61, the respective decennial averages (1908–17) having been 18·72 and 34·02. Dr. Turner, however, reckons the true birth-rate to have been 30·12 and the true death-rate 56·28. The infant mortality is estimated at 434·82 per 1000 births (including those unregistered), compared with 304·25 in 1917 and 278·48 in 1916; the total number of infantile deaths was 12,829, of which 4648 were due to respiratory diseases, 3069 to debility, and 2033 to affections of the nervous system. Of 14,442 infants born in one-roomed tenements 76·72 per cent. died, of 2117 born in two-roomed tenements 49·88 per cent. died, while of 4051 infants born in hospitals only 7·92 per cent. died, thus clearly proving that "the appalling mortality" is to a very great extent preventable. Much good work is being done by municipal nurses and health visitors under the scheme inaugurated by Lady Willingdon in 1914; which, moreover, now supplies pure pasteurised milk, not only for the children born in the three maternity homes that have been established, but also for those born under the supervision of the health visitors or municipal midwives; milk to the value of about 700 rupees (say, £70) being distributed every month. It is now proposed to open infant welfare centres in various parts of the city to give advice to mothers and medical aid to infants and to establish day nurseries.

The total number of deaths registered was 58,388 (compared with 33.390 in 1917); this gives a ratio of 59·61 per 1000, considerably higher than the decennial average of 34·02, and higher than in any year since 1905, when it was 61·54. But, as Dr. Turner points out, 3274 of these deaths (including 1230 deaths in war hospitals) occurred among new arrivals not belonging to Bombay; by deducting these, and adding the deaths of Bombay inhabitants that occurred in their houses up country, a corrected total of 55.128 deaths gives a ratio of 56·28 per 1000 on the 1911 population. "Such an estimate is desirable, as it marks a greater approximation to the truth than the bare statement of the number of deaths in the population." It is often said that statistics may be made to prove anything, but qualifications of this kind are absolutely necessary to obtain as near an approach to accuracy as is practicable. Of the total mortality of 58,388, about 40 per cent. was due to respiratory diseases (23.487 deaths, of which 10,107 occurred in September and October). The ratio was 23·97 per 1000, compared with 9·42 in the preceding quinquennium; presumably it was connected with the influenza epidemic. During September the total deaths in the city rapidly increased from 102 on the 10th to 712 on the 30th. On Oct. 6th there were 768 deaths, of which 161 were recorded as influenza, and 461 as due to respiratory diseases. During the worst plague epidemic the highest total mortality on a single day had been 433 on Feb. 16th, 1900. Great efforts were made to meet the emergency by the Medical Relief Committee of the Corporation and the Municipal Commissioner. Posters and leaflets were circulated urging the people to go to hospital on the appearance of sickness, and offering free treatment, milk, and "pneumonia jackets." Temporary or "table" dispensaries were put up in the poorer parts of the city to the number of about a hundred; temporary hospitals were opened by different communities, Parsees, Jains, and others in various parts of the city. Special wards were placed at the disposal of the health authority in various hospitals; the military authorities lent the use of 400 beds, and also lent hospital orderlies and ambulances and cots; the Western India Turf Club lent their offices as an intelligence bureau; the Red Cross Society supplied sleeping-suits. By such energetic and efficient action the progress of the disease was arrested after 62 days. The actual number of deaths above normal for this period was 20,258, averaging 326 per day—that is, in a *yearly* ratio of 108·17 per 1000 of the estimated population (or of 121·48 per 1000 of the population according to last census).

Tuberculosis and Other Fevers.

Tuberculosis caused 2513 deaths (2·56 per 1000), a higher incidence than in 1917 (2·16), and the quinquennial mean (1·99). Mussalmans suffered most (3·99), and next to them Eurasians (3·82); Parsees suffered least (0·96), and next to them Jews (1·36) and Europeans (1·42). The King George V. Anti-Tuberculosis League carries on both prevention and treatment in coöperation with the Health Department. Enteric fever, "malaria," and "ague and remittent" are classed, together with scarlet and relapsing fevers, under the head of "All fevers." From the combined diseases there were 4553 deaths, compared with 2449 in 1917; the enteric deaths were 125, those from "malaria" were 200, while from "ague and remittent fever" there were 4219, compared with 2012 in 1917, and 2132, the quinquennial average. A severe outbreak of cholera (the worst that has been experienced within the last 30 years) commenced in December, 1918, and lasted until the end of February, 1919; there were 396 cases in December and 973 in January and February, amounting to 1369 during nine weeks. The case-mortality was 56·9 per cent. in 1918 and 52·8 in 1919. More than half the deaths occurred within 24 hours of admission to hospital, the patients being already semi-moribund. Dr. N. H. Choksy, assistant health officer in charge of the Arthur Road Hospital for infectious diseases, states that the relative fatality of the disease varies considerably with the social condition of the patient; among Parsees it has been found to be 28 per cent.; Europeans, 31·0; Mahommedans, 47·5; and Hindus, 53·4 (statistics of 1910 to 1919, including two epidemics).

Plague.

The same officer reports on the work of the Maratha Plague Hospital, which was also used for the treatment of infectious diseases, supplementary to the Arthur Road Hospital; 328 cases of plague were admitted, of which 263 were fatal (80·1 per cent.). The treatment of this disease by subcutaneous injections of colloidal preparations has now been carried out during two full epidemic periods, 107 cases having been so treated during the year under report out of the total 328 admissions; all moribund and semi-moribund cases, convalescent and semi-convalescent patients, and all whose illness had lasted six or more days were excluded, and the treatment restricted "to the most acute cases from the first to the fifth day of illness who clinically exhibited some chances of recovery." Of the 107 patients thus treated, 75 died and 32 recovered, giving a case-mortality of 70 per cent. By grouping these cases with those similarly dealt with in 1916 and 1917 it was found that of a total of 295 the case-mortality was 64·4 per cent.; in 222 cases treated in a similer manner by the Plague Commission in 1909–12 the case-mortality had been 66·2 per cent. The best results were obtained with collosol iodine (106 cases with 59·4 per cent. case-mortality), collosol argentum (93 cases, 64·5 per cent.), and iodeol (63 cases, 65 per cent.).

Conclusions.

In the concluding paragraphs of this very able report Dr. Turner mentions that, as far back as 1914, he pointed out that the expenditure on public health administration was, in proportion to the population, less than it had been in 1901; that proposals for improvement had been made, approved, and sanctioned, but not carried out; that the Health Department had been starved financially, and that no improvement could be made in the city unless a larger view is taken of the situation. The population has increased from 776,000 in 1901 to over 1,200,000 in 1919; the rateable value has risen from 286 to 754 lakhs of rupees, while the expenditure on public health works has decreased from 28 per cent. to 17 per cent. of the total. We regret to learn that this is Dr. Turner's last report as executive health officer. Though Kipling says that "East is East and West is West, and never the twain shall meet," as a matter of fact they do meet in Bombay, where the great majority of people who visit India make their first acquaintance with the "gorgeous East." The sanitary welfare of Bombay is a matter of importance to the whole Indian Empire. If the civil authorities neglect to act on the recommendations of their skilled and experienced adviser on matters affecting the public health they assume a very grave responsibility, for which, sooner or later, they will undoubtedly have to give an account.

NORWICH NON-MEDICAL CORONERS AND NECROPSIES.

THE attitude of a non-medical coroner to the performance of necropsies on persons who have died suddenly has recently aroused some interest in Norwich. A woman, aged 75, had been for some time last summer under the treatment of a doctor. On the morning of Jan. 6th she complained to her son of having had a bad night, and said she was suffering from pain in the chest and "wind round the heart." Shortly afterwards she went out to a shop to buy meat, and while there she collapsed and fell. The police ambulance was sent for, and the policeman in charge, believing the woman to be dead, took her to the Norfolk and Norwich Hospital, where the house surgeon pronounced life extinct. At the subsequent inquest the house surgeon stated that he had performed a post-mortem examination, and that the cause of death was valvular disease of the heart. The city coroner, Mr. W. N. Ladell, commented on what he considered the irregularity of the proceedings. He said that if a person was found dead the police had no business to remove the body to the hospital; that this woman should have been removed to her home and a doctor—the police surgeon if possible—called in to pronounce whether life was extinct; and then that his (the coroner's) instructions should have been awaited. The coroner considered that no post-mortem was necessary in this case, as the woman had been attended by a doctor, who could have been called. He stated that in future no post-mortem was to be made in similar circumstances without instructions from the coroner. As no such instructions had been given, he refused to allow the house surgeon a fee for the post-mortem, though he paid him his fee for giving evidence.

BOILING WATER FOR INDIGESTION.

AN inquest was recently held at Hayle, Cornwall, relative to the death of a man, aged 44 years. Evidence showed that the deceased "sipped a cup of boiling water to cure indigestion." Medical evidence stated that "death was due to suffocation, owing to œdematous laryngitis caused by drinking boiling water," and the jury returned a verdict that death was due to misadventure.

MONTHLY VITAL STATISTICS OF LONDON.

To the Editor of THE LANCET.

SIR,—In the table of Analysis of Sickness and Mortality Statistics in London during November, 1919, which you published in THE LANCET of Dec. 13th, 1919, I observe that the figures are apparently based on the "Estimated civil population of London in 1917." This basis was commenced to be used first in THE LANCET of March, 1918, and some of those who follow the tables may be wondering why, with the end of the war and demobilisation, this old basis is still being used.

I am, Sir, yours faithfully,

Jan. 17th, 1920. ENQUIRER.

*** For some time past now the official weekly returns issued from Somerset House have explained this apparent anomaly by printing the following footnote, which will answer our correspondent's question:—

> The estimates of population refer to the year 1917, and are based on the returns furnished under the National Registration Act, 1915, and under the scheme for rationing of sugar. It is necessary for the present to continue the use of the estimates of population as in 1917, because those for 1918, although they might now be used, would necessarily differ more from the facts of the present time than the earlier estimates. The main change which occurred between mid-1917 and mid-1918 was further depletion of the male civilian population by enlistment, and as this has now been more than made good by demobilisation, it follows that the 1917 estimates, though they understate the present population, do so to a less extent than would those for 1918.—ED. L.

An Address

ON

THE POSITION OF THE MEDICAL PROFESSION IN RELATION TO NATIONAL PHYSICAL EDUCATION.

Delivered before the Royal Society of Medicine on Wednesday, Jan. 21st, 1920,

BY K. DIGBY BELL, M.R.C.S., L.R.C.P.LOND.,
SURGEON COMMANDER, ROYAL NAVAL SCHOOL OF PHYSICAL AND RECREATIONAL TRAINING, PORTSMOUTH.

THE study of physical education has been my hobby since 1906, when I was first appointed on the staff of the R.N. School of Physical Training at Portsmouth. At that time I realised that the subject was essentially one worthy of the full attention of the medical profession. Since 1906 the Admiralty has given me many opportunities of studying the subject theoretically and practically outside the navy as well as in it, under varied conditions and in many countries. I have had a year's course at the Central Gymnastic Institute at Stockholm. Of the several billets I have held I feel the most interesting and important has been that to which I was appointed during the four and a half years of war.

In 1914 (after the ship I was then serving in, *Audacious*, had been sunk by mines) I was appointed as one of the medical officers in *Iron Duke*, the flagship of Admiral Sir John Jellicoe, and remained on in that ship when Admiral Sir David Beatty took over the command of the Grand Fleet. I was fortunate enough to be taken over in 1917 to *Queen Elizabeth* when the flag was transferred to that ship. I combined with my duties of junior medical officer in the ship the position of adviser in physical training matters to the Commander-in-Chief. Hence I was kept in constant and close touch with the sports and recreations of the Fleet.

The development of physical training in the navy started in 1902, when the Admiralty decided it was necessary to have a Central Headquarters School of Physical Training in the navy for the purpose of training officers and petty officers to be instructors. After full discussion and inquiry the Swedish system was chosen as being the most suitable for practical application to a large number of men and boys, and for the training of an all-round type of physique. In 1903 the services of Mr. Broman, who was a third-year graduate of the R.G.C.I. of Stockholm, were obtained. He gave his services for six weeks to introduce to the navy the Swedish system of gymnastics. From that date until the commencement of the war the work done at the Headquarters School of Physical Training has been progressive.

At the commencement of hostilities in 1914 the Physical Training School at Portsmouth was closed, so the supply of instructors was cut off.

RECREATION A NECESSITY.

During the war many valuable lessons have been learned by everybody, and especially has this been the case with regard to our methods of physical training. Up north in the Grand Fleet the spectre we had to consider seriously was the possible onset of a depression due to the incessant nervous strain and ghastly monotony. There we had our men-of-war crowded to their utmost limit with virile human beings, buoyed up with the daily hope that with to-morrow would come "The Day." That to-morrow gradually became weeks and months, and the months extended to over four years, with the ever-haunting thought that another winter was coming on. When it is realised that the mere sight of a tree filled thousands of men with a thrill of intense joy; that to get mud on their boots even once a month was a thing to be proud of to those whose blood called for natural exercise; that they lived in a home in which they could never get away by themselves for one moment's peace; the sort of restless monotony of their lives is not difficult to appreciate. That this monotony cannot be said to have affected the morale of the sailor to any extent was due in great part to the ever-watchful care and forethought of those in charge of units and squadrons in the Grand Fleet. The lesson learnt was that recreation, and more recreation, of a simple and attractive nature for *all* on board ship was wanted. It was always possible to keep the 10 per cent. who excelled at games amused and energetic. They would roller-skate, box, dance, or do anything to keep themselves fit and cheery when weather and other conditions made landing impossible. But it was the 90 per cent. who did not excel at games on whom we had to concentrate, in order to kindle enough energy to shake off the dull and listless mood into which they were unconsciously drifting. Recreational committees were formed and schemes worked out to assist those ships less fortunately equipped and situated. Physical training began to be looked upon in a much bigger light; the study of amusements of a healthy and stimulating nature for the whole community was embodied in it; the need for that psychological element of personal touch between officer and man was never more apparent. So when the Physical Training School was revived at Portsmouth early last year, 1919, the subject had also to be reviewed afresh.

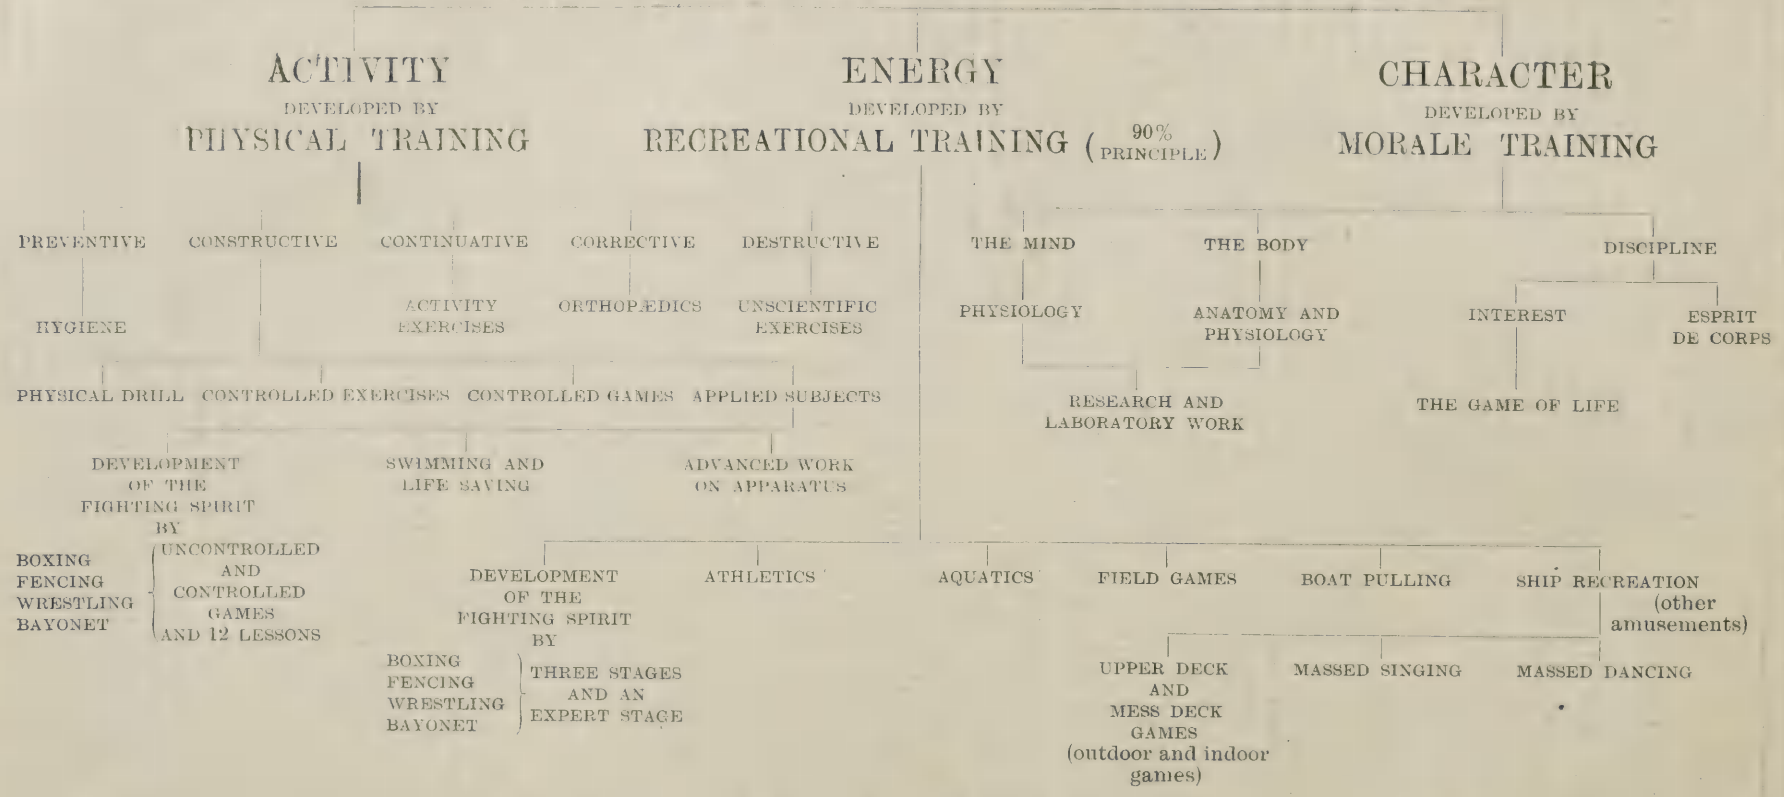
This element of recreation had also been realised as an integral part of the scheme of training in our armies at home and abroad. That exceptionally fine system of treating the trench-weary soldier had been inaugurated by Colonel R. Campbell, D.S.O., at his headquarters of Physical and Bayonet Training at St. Pol. It had to be realised that physical education embodied a larger field of study and research now than was ever believed in pre-war days.

EXPLANATION OF SCHEME OF PHYSICAL EDUCATION.

I will try to deal with the result of war experience with regard to the reconstruction of our ideas. I particularly wish to place before you a chart of physical education. It is naturally incomplete, but I think it is admirably suited to form the basis of a national scheme of physical education, and will endeavour to prove this. At present we are using it as the groundwork of our scheme for training the officers now under instruction at the R.N. School of Physical and Recreational Training (see chart attached).

We divide physical education into three main headings: (*a*) activity developed by physical training; (*b*) energy developed by recreational training; (*c*) character developed by morale training; and though for the purposes of description I shall run quickly over the branches radiating in sequence from each main heading, yet it must be understood that every portion of the chart is interdependent, the development of character being an object of the recreational training just as the recreational

PHYSICAL EDUCATION



THE GAME OF LIFE

1. RULES—
   1. DON'T PLAY FOUL
   2. DON'T CHUCK THE SPONGE UP
   3. GO ALL OUT TO WIN
   4. PLAY FOR YOUR SIDE and NOT FOR YOURSELF

2. REQUIREMENTS—THE ACHIEVEMENT OF THE HIGHEST HUMAN ENDURANCE THROUGH

1. STOMACH	FOOD	
2. HEALTH	FULL BODILY MOVEMENT	
3. SENTIMENT	SONG and DANCE	
4. HAPPINESS 5. COMRADESHIP	INDOOR and OUTDOOR RECREATION	ON THE 90% PRINCIPLE

3. ACQUIRED BY—SIMPLICITY and ATTRACTIVENESS

4. RESULT—MENTAL AND PHYSICAL ACTIVITY LEADING TO PERFECT MORALE

training is, after all, an essential part of physical training.

Activity is health—the two are inseparable. We all of us realise that as long as a child is active he is in good health; we become anxious at once if his activity wanes or is replaced by listlessness.

(A) *Physical Training.*

So we study activity in our development of physical training which deals with measures which are: Preventive, Constructive, Continuative, Corrective, Destructive.

Preventive measures are dealt with by lectures on the anatomical and physiological hygiene of the body, pointing out those elements of daily existence which are harmful to the development of a healthy and active frame. Anatomy and physiology naturally come prominently under this heading.

Constructive measures speak for themselves. They involve the application of bodily exercise to the young to ensure as perfect a body as it is possible to acquire. The subject is dealt with under the following headings: (*a*) *Physical drill.* This may be defined as the application of any bodily movement to produce a spectacular effect rather than a constructive effect. An instructor can apply drill, but a teacher works for the constructive effect on the bodies and minds of those he is training. (*b*) *Controlled exercises* embody the minute study of the application of the Swedish system of gymnastics made attractive so as to suit the characteristics of our nation. (*c*) *Controlled games* consist of a large series of those games, taught in the uncontrolled stage under recreational training, which a teacher may wish to employ in his gymnastic table to provide an attractive setting for constructive exercise. (*d*) *Applied subjects* are the connecting link between physical and recreational training, but more easily dealt with under the former heading.

Continuative.—No system of education which dose not ensure continuity should be worthy of consideration.

It is necessary to understand the difference between what may be called educative physical training—that is to say, the definite constructive development of the bodies of young and growing people, and the maintenance of physical fitness in the fully developed bodies of those of maturer age. There comes to the latter, sooner or later, a desire for physical improvement, and with it a conviction that some form of daily exercise is necessary to ensure bodily health and activity. Activity exercises have been compiled for this purpose. They are simple in character, take two minutes to do, and provide full and free movement of the body in an interesting and attractive form.

Corrective.—Orthopædics is a subject which at once calls for the knowledge and assistance of the medical profession and for the research work embodied in the last heading on the chart.

Destructive.—A teacher of physical education should know what evil effects may accrue from an injudicious use of bodily activities. This subject is dealt with by lectures and practical demonstrations of such unscientific exercises, done with or without apparatus, which can be proved to be destructive both anatomically and physiologically.

B. *Recreational Training.*

Here we have an essential element in the scheme of physical education. It is the very foundation of the science. It provides measures for dealing with all types of pure recreation, and must be applicable to the majority rather than the minority. We all know the inestimable value of the sports and games in our own schools and universities. But there are those whose football and cricket consisted more often of noisy squabbles and fighting than of playing for their side; whose only chance of learning something of our so-called national sports was by watching a football match where 22 paid players performed and thousands looked on.

Recreation develops energy, and energy is dwindling because more people are willing to watch than to take part; 10 per cent. wish to play and 90 per cent. are content to watch.

This term—the 90 per cent. principle—is used in connexion with the recreational training scheme depicted on the chart, and requires brief explanation. It is agreed that perhaps 10 per cent. of the population have a natural tendency to excel at sports and games. In the past the needs of these have been specially catered for. The 90 per cent. have never indulged systematically in sports and games, principally because they have not had the opportunity, or possibly they have been discouraged by their lack of ability to compete with the 10 per cent. This scheme of recreational training applies principally to the 90 per cent., and provides for them an immense range of physical and recreational activities, a new and hitherto undeveloped incentive to enjoy them, and an organisation whereby the utmost advantage as regards development of energy and character may be secured. The six subheadings, development of the fighting spirit, athletics, aquatics, field games, boat-pulling, and other amusements, must be understood to cover something quite apart from their everyday meaning. A Recreational Training Handbook, which deals only with this subject, has been compiled, though not yet published, and contains these six sections:—(i.) Energy exemplified. (ii.) The classification of physical effort. (iii.) The standardisation of all physical activities (300 and more types to date). (iv.) The method of rewarding 90 per cent. (collective) effort. (v.) The introduction of the scheme. (vi.) Musical activities. The headings on the chart under which this recreational training is developed speak for themselves.

The development of the fighting spirit is obviously fostered by the practice of certain sports involving the use of weapons. From a national rather than a naval point of view such pastimes may be considered inadvisable. It may be said they produce the idea of a hateful militarism, the savour of war. The heading could be left out, or the subjects taught could be those which develop the spirit of self-defence. Be that as it may, the methods of teaching the sport chosen are conducted on the same lines, first as an *uncontrolled* game, then *controlled*, with at first one simple rule which must be kept, then another rule, and so on until the game is completely controlled, the pupils themselves acting as judges to see fair play or to penalise any breach of the rule. The next stage is that of *90 per cent. contests*, in three degrees, and an expert stage, so that *all* can compete without having their interest in the game cramped by the 10 per cent. who excel. *10 per cent. competitions:* Championships as usually held to-day. In this manner athletics, aquatics, fixed games, boat-pulling, ship recreation (which in a national scheme would read other amusements) are also conducted.

For example, let us suppose a school wishes to run an athletic sports meeting at which *every single boy* is to compete, and his individual effort is so marked as to have an important bearing on the result for his house.

We look at our Classification of Physical Effort in the Recreational Handbook to choose an event from each heading, so that the programme of sports will be representative of all the necessary degrees of effort, of which we find 11 headings. Now for one of these (the agility part of our programme) we may choose the 100 yards race. Every boy has to run and the time he takes to cover the 100 yards is converted into a percentage on a known factor of skill, which represents his share towards the aggregate marks of his house. Then by a simple score-sheet (the arrangement of which is all explained in detail) the average marks of the whole team or house are arrived at, and every single competitor can feel he has done his bit, and thus energy and his desire to "go all out" for his side is cultivated and encouraged.

Massed Singing and Dancing.

Of the heading "ship recreation or other amusements" I would like to add a few remarks. For upper deck and mess deck games could be substituted outdoor and indoor games (of which we have collected a great number). In massed singing we have a really interesting psychological element. We sing when we are happy and cheerful, and by encouraging massed singing we can intoxicate crowds into being happy and cheerful. Music deals with the sentimental side of a nation's character, and true sentiment is an overpowering force which can be guided for good or evil. Patriotism and love of our Alma Mater are developed and stimulated by suitable songs, and for this reason the subject is revived here. The bluejackets simply revel in participating in our musical activity evening at our Portsmouth school, and sing folk-songs and sea chanties with great zest.

Massed dancing is another way of dealing with sentiment. The war opened our eyes to the power of dancing as a recreation; evening after evening on the upper deck of our big ships we could hear over our heads the swish and stamp of the feet of hundreds of sailors pacing out the D'Albert or Valeta. That dancing appeals to the mass of our nation is more and more apparent. I am not alluding to the Jazz craze, but to the more stately and graceful dances, and the simple country, Morris, and sword dances.

C. *Character Developed by Morale Training.*

Herbert Spencer wrote: "Of the ends to be kept in view by the legislator, all are unimportant compared with the end of character making—this alone is national education." The development of character permeates the whole of this scheme of physical education. In the scheme shown it is dealt with under headings which are particularly the work of the medical man. Lectures on psychology and on the psychology of teaching are given. Lectures, assisted by the microscope, magic lantern, and specimens, deal with the simple truths of cell life, of elementary botany, and of reproduction. The sex question is developed at some length. I am one of those who have learned by experience the importance of instructing the young, simply and normally, to know the truth about their bodies, thus cultivating self-reverence and self-control.

These subjects are all included under the headings on the chart—the mind, psychology, the body, anatomy, and physiology. Though the subject is dealt with here in as practical a manner as possible, it is realised that in a national scheme, where its survival in a nation must be aimed at, the study of character would be further developed under other headings—e.g., religion, idealism, ethics, &c. Research and laboratory work is needed, and will undoubtedly come.

Discipline is a subject of the utmost importance these days, when both employer and employed should be trained to understand its intricate nature.

We deal with it on the lines of *esprit de corps* and interest as opposed to a discipline by fear of punishment, as far as the young are concerned. The last item on the chart is put down as "The Game of Life" for want of a better title. It embodies in it the whole ideal of this system of physical education; it must be not only understood, but brought into every development in order to ensure success. Its spirit is being inculcated into the youth of the nation by the "Boy Scouts" movement. I cannot help feeling myself that had it been embodied into our whole educational system for the last 10 years or more, the industrial unrest of to-day and the use of the strike weapon might never have shown themselves.

WHY WE ARE A C 3 RACE.

Such are the lines on which we are trying to reconstruct our methods and teaching at the Naval Physical and Recreational Training School at Portsmouth, and anyone desiring to come and see the work in practice will be welcomed.

That some system of national physical education is necessary to-day has been made only too forcibly apparent to us all. It must have been a shock to every thinking man to realise that during the critical days of the last year or two of the war only 36 per cent. were fit to fight. Certain words used by General Sir H. S. Horne, speaking at Bradfield College early last year, have never to my knowledge been contradicted, though I had hoped they might be. The papers quoted him as having said: "It was utterly scandalous that the British should have ranked at the bottom—he had not the figures, but he believed at the bottom—of the list as regards physical fitness of the nations from whom they were able to obtain statistics during the war."

I personally feel there are three great reasons why we found ourselves to be a C 3 race: (1) We have allowed the spirit of competition to concentrate on the training of a few specialists in one or other of our national sports, to the detriment of the mass of less fortunate citizens, who are not considered worthy of attention, as they perhaps do not shape well. I pointed out in a lecture to the United Services Medical Society in 1909 that specialising in one or other kind of sport was one of the evils gradually depressing the all-round physique of the whole nation. I said then that if we were to go to war it would be the all-round physique we should want, and want in vain, and unfortunately I have not been proved wrong. (2) The fact that the subject of physical education has not been taken up seriously by the nation, but has been left to private enterprise and so-called experts in various methods. The instructors have often had only a few weeks' instruction in how to conduct stereotyped exercises. So far as men are concerned, the Swedish system of gymnastics has never been appreciated in this country. There are several women's colleges where two years' training was the minimum, and this is now being extended to three years. The type of instructor employed is another point in this connexion. We need the university student, the officer rather than the man, and, moreover, central control by the Government is essential. (3) The most important reason for our physical deficiency, in my opinion, is the fact that the subject has not been studied sufficiently by doctors. Our medical schools teach anatomy and physiology more with the ultimate object of curing disease than of preventing it.

The chart I place before you to-day is far from being my work or that of any medical man; but it is the result of 17 years' practice and constant study on the part of a retired naval officer of the combatant branch—Commander B. T. Coote—who is at present assisting us at Portsmouth in the capacity of civilian adviser to our school. The teachers (where there are any) and the instructors at our boys' schools in nearly every case have no medical training, nor even in most cases the support of the school doctor. I hold that until the movement is taken up wholeheartedly by the medical profession it will lack the public support essential to its success.

NEED OF A SYSTEM OF PHYSICAL EDUCATION.

This brings me to the crucial point which I have set myself to place before you. The country urgently needs a more comprehensive and a better organised system of physical education, and, gentlemen, it is up to our profession to see that it gets it. I do not presume that you should go away with the idea that this chart depicts *the* system that is wanted; I place it before you for want of anything better. It certainly treats the subject in its proper sphere of importance and magnitude, and it forms a basis for thought and future development when more research is devoted to the subject. I do not wish to infer that the navy alone realises the necessity for recreational training. The army and Air Force have adopted such methods for some time past, and we are all working on the same ideas for one national object. The Board of Education also has recently published a new syllabus of Physical Training for Schools (1919) giving suggestions to their teachers in which the importance of games of all sorts is distinctly realised, and a certain number of indoor and outdoor games are suggested. But a central controlling body of this huge branch of preventive medicine is needed to-day. We have now a Ministry of Health. Could not this or another Government body be approached by a strong appeal from the medical profession of Great Britain for: (1) The formation of a National Council of Physical Education to study and elaborate the lines our national system of physical education should take; (2) the formation of a British Physical Educational Association on some such lines as our present British Medical Association, to control all members practising physical education in Great Britain; (3) the formation of a Central Gymnastic Institute where teachers of physical education could be educated on such lines as would be directed by the national council, and obtain the certificate of the association mentioned above.

The matter is urgent. The Prime Minister himself coined the expression that we are a C 3 nation from the facts given him by the medical profession, and he said we must become an A 1 nation if we want to remain a great empire. But a lethargy seems to overshadow the question as to who is to take action. Early last year the headmasters of our big public schools included the subject of physical education in their Annual Conference. The President of the Conference says:—

> "I approached the Board of Education in my capacity as chairman of the Headmasters' Conference to push for proper Government control with regard to training experts of physical education—i.e., the necessity for a National College of Physical Education. I was given clearly to understand that the Board of Education could not view matters in this light and considered such a development should be left to private enterprise."

Last May the United Services held a Physical Training Conference at which were present representatives of our colonies and a member of our Board of Education. There were many issues under discussion, but the most important one was round the problem of creating a central organisation such as a Physical Training University for the Empire as a whole, to embrace all classes, civil and military. The proceedings ended in the formation of a subcommittee consisting of one member from each of the Services with the representative of the Board of Education to sit as chairman (subject to approval of the Board of Education), and I had the honour of being elected as the naval representative. This subcommittee was to prepare a paper to be submitted to the main conference with a view to its being put before the Government. This subcommittee was to be called as soon as information was received that the Board of Education had sanctioned their representative sitting as its chairman. That was on May 20th, 1919. It is now Jan. 21st, 1920, and no subcommittee has been called. Who is to take action? The headmasters have failed, the desire of the United Services met with no response; but the medical profession may succeed in awakening the country to the necessity of such a measure of preventive medicine.

An Address

ON THE

INDICATIONS FOR CÆSAREAN SECTION.

Read before the Midland Obstetrical and Gynæcological Society at Derby on Dec. 2nd, 1919,

BY H. BECKWITH WHITEHOUSE, M.S. LOND.,
F.R.C.S. ENG.,

HONORARY ASSISTANT GYNÆCOLOGIST, GENERAL HOSPITAL,
BIRMINGHAM.

GENTLEMEN,—In 1752 Mauriceau, in his "Diseases of Women with Child," referred to the operation of Cæsarean section as "a damnable policy martyring and killing the mother to save the child, and never to be done till the mother was dead." In 1910, or 158 years after Mauriceau's very plain-spoken observation, Amand Routh published his report upon Cæsarean Section in the United Kingdom before the Fifth International Congress of Obstetrics and Gynæcology at Petrograd. For the purpose of this investigation Routh collected material from over 100 obstetric surgeons, and was able to accumulate details of 1282 cases. The paper may claim, therefore, to represent the current views relating to this operation in the United Kingdom at that time. Almost ten years have elapsed since its publication. Nearly five of these years have been occupied by war, but throughout this period, although very little has been published, the science and art of obstetrics has continued and, we hope, progressed. During and after years of conflict the lives of mother and child are of the highest national importance. The present appears an opportune time, therefore, to discuss the indications for an operation designed to eliminate maternal and fœtal mortality. Are the risks of Cæsarean section lessened, and have its indications become extended as the result of the publicity of Amand Routh's paper?

In every obstetric operation, whether it be performed by nature *per vias naturales* or by the surgeon, certain postulates must be fulfilled before an unqualified success can be claimed. These may be enumerated as follows: 1. There must be no maternal mortality. 2. There must be no maternal morbidity. 3. A living and viable child must be born. The factors which demand consideration, therefore, in discussing the indications for Cæsarean section compared with other methods of delivery in difficult labour are, on the one hand, maternal mortality and morbidity, and on the other fœtal viability.

The first observation that I would make is that I believe the popularity of Cæsarean section amongst obstetric surgeons is increasing. No figures have recently been published, but information obtained from various sources goes to show that the method of delivery is not approached to-day with the same feeling of apprehension that it engendered a few years ago. It is probable that if a similar investigation was now conducted as that by Routh barely ten years ago a much greater fund of material would be available. With increasing confidence and detailed technique the mortality of Cæsarean section also appears to be diminishing, and it is more than possible that an era will arrive when the operation is considered to be the safest mode of delivery in the majority of cases of complicated labour.

Broadly expressed, the indications for classical Cæsarean section, and it is with this operation alone that the paper is concerned, may be divided into two groups.

(*a*) Cases where a definite obstruction to the passage of the child exists, either from disproportion between the fœtal and maternal bony parts, malpresentations or neoplasms, &c.

(*b*) Cases where urgent delivery is called for in the absence of previous dilatation of the birth canal either for the sake of (1) the mother, as in eclampsia; (2) the child, as in placenta prævia.

THE PLACE OF CÆSAREAN SECTION IN CONTRACTION OF THE PELVIS.

What is the present-day view with regard to Cæsarean section as the method of treatment in cases of pelvic contraction? The three other modes of procedure available are: (1) induction of labour before term, (2) symphysiotomy or pubiotomy at term, or (3) craniotomy. A few years ago we used to direct our conduct by the measurement of the conjugata vera. If the latter measured 2½ inches to 3 inches Cæsarean section was the method preferred, provided the membranes were intact. If, however, it measured over 3¼ inches and the head presented, the indication was to induce labour at the thirty-fifth week. Personally, I lay less and less stress upon pelvic measurements and place more and more importance upon Müller's method of adapting the fœtal head to the pelvic brim. It appears futile and grossly unscientific to pin one's faith upon a measurement when after all it is but relative to another factor which is unknown. Müller's method is of great value in estimating the moment when it is advisable either to induce labour or to decide upon a section later on. This raises the problem as to whether after all we *are* correct in inducing labour. The maternal mortality of induction is certainly nil, whilst in Routh's series of cases the maternal mortality of uncomplicated Cæsarean section is 2·9 per cent.; in other words, that of other gynæcological cœliotomies. However, the fœtal mortality in induced labour is still considerable. Thus Eden states that out of 309 cases of pelvic contraction at Queen Charlotte's Hospital during the four years 1905–1908 101 had a premature labour induced by Krause's method. The fœtal mortality was 13 per cent. The average weight of the infant was from 5 to 5½ lb. The argument therefore resolves itself into whether we are to risk a possible maternal mortality of 2·9 per cent. for the sake of lowering the high fœtal death-rate of 13 per cent? Personally I am of the same opinion in this respect as Hastings Tweedy, and think that induction is not advisable. A woman risks a mortality of 2 per cent. to get rid of a fibroid; why should she not therefore risk a similar mortality for the sake of a healthy living child at term?

Pubiotomy and symphysiotomy will never, I believe, have a wide application owing to the high maternal mortality and morbidity. Thus in Munro Kerr's series of 275 cases of symphysiotomy from all sources the maternal mortality was 6·5 per cent. and the fœtal mortality 10 per cent., not very encouraging, to say the least. Herbert Spencer has published considerable data relating to the morbidity of pubiotomy, quite sufficient anyway to discount any possible advantages of the operation.

I turn now to the vexed question of the place of Cæsarean section in those cases where the membranes have ruptured and delivery has been attempted per vaginam—in other words, the so-called "suspect cases." This group is, and as long as it occurs will always be, a stigma upon the medical profession. If women were properly examined during the later months of their pregnancy disproportion between the fœtal head and the pelvic brim would be discovered, and these cases would not occur. Every case of obstructed labour at term from this cause is a reflection upon the obstetric skill and care of the medical attendant. The risk of Cæsarean section, once repeated and persistent attempts at delivery by high forceps have failed, is magnified nearly 15 times. In Routh's figures the mortality of the operation in cases where attempts have been made to deliver by forceps or where repeated examination has taken place is 34·3 per cent. Simple rupture of the membranes without examination is not such a grave accident, although serious enough. The mortality in such patients is 10·8 per cent. What is the alternative procedure? It is, of course, craniotomy, with its maternal mortality of 8 per cent. and a morbidity of 20–30 per cent. If the child is dead there is, of course, no question as to which is the proper procedure. What is to be done, however, when the child is alive? Personally, I would not perform craniotomy upon a living child. I have been confronted with the problem upon two occasions recently, and in each case I deliberately chose to deliver by the abdominal trans-peritoneal route, previously employing Maxwell's method of intra-amniotic lavage with saline. I was lucky in that both mothers recovered without morbidity. In a case obviously septic my practice would be to drain the pelvis into Douglas's pouch, with possibly a lateral rubber drain into each flank. I await discussion of these points with considerable interest, as I recognise that I am on highly debatable ground.

INDICATIONS OF CÆSAREAN SECTION FOR UTERINE HÆMORRHAGE.

Ante-partum uterine hæmorrhage occurs, of course, in the form of accidental hæmorrhage and bleeding due to placenta prævia. Has Cæsarean section a place in the treatment of either condition? In the case of concealed accidental hæmorrhage with a tense tender uterus with inertia the operation is most certainly called for. Most people are agreed that in order to save the mother Cæsarean supravaginal hysterectomy is the correct procedure. The mortality of the complication is high, and the only method of reducing it is to proceed at once to Cæsarean hysterectomy without attempting other methods and wasting valuable time.

What is to be done, however, for placenta prævia? The maternal mortality is not great, varying in different clinics from 2·5 to 3·5 per cent. In a series of 41 cases recorded by Hastings Tweedy during the seven years of his mastership of the Rotunda Hospital two mothers died. The fœtal mortality is, however, appalling. Thus, in Tweedy's series of 41 cases 24 of the children were born dead. This high fœtal mortality is, of course, due to two factors; the first is the separation of the placenta and the interference with the fœtal circulation; the second is the method of treatment by version and bringing down a leg, a method designed to save the mother at all costs at the expense of the child. When Amand Routh published his report ten years ago the general opinion of British obstetricians was that as a routine treatment of placenta prævia there was no place for Cæsarean section. This opinion was expressed in a discussion upon a paper read by Dr. Henry Jellett, and the only recognised indication for Cæsarean section was "where the cervix was so rigid and undilatable that the treatment by bi-polar version as first suggested by Braxton Hicks was impossible." As I have already stated, however, no treatment is satisfactory which does not bring maternal and fœtal mortality to its lowest limit. The arguments advanced in favour of bi-polar version are all to the credit of the mother and to the debit of the child. Is this right, and if wrong, can it be altered? It appears to me that if by means of an operation with a mortality of little more than 2 per cent. we can afford a saving of fœtal life and lower the terrible fœtal mortality of the generally accepted method of bi-polar version that operation ought to receive more attention. Kronig and Sellheim publish 26 cases of Cæsarean section for placenta prævia with no maternal mortality, and, mark this, no fœtal mortality. In the available statistics every attention is paid to maternal mortality, and it is argued that as the existing method of delivery is so safe for the mother, why alter it? The infant is quite a secondary consideration. I would combat this argument in the strongest terms. If a method is available in which, without imposing undue risk upon the mother, the child may also be saved, then, in my opinion, that method should be adopted. In other words, if in a case of placenta prævia the child is alive and of a viable age I would unhesitatingly resort to Cæsarean section in preference to risking the child's life by bi-polar version. The indication for the operation will depend, therefore, entirely upon the date at which the placenta calls for evacuation of the uterus. If hæmorrhage occurs at a period before there is a reasonable chance of the child surviving, and, of course, if it is so severe as to have caused fœtal death, then bi-polar version is the operation of choice.

THE INDICATION FOR CÆSAREAN SECTION IN ECLAMPSIA.

The third and last group to which I wish to draw your attention is the place of Cæsarean section in the treatment of ante-partum eclampsia. The argument in favour of rapid evacuation of the uterus in this condition must rest, of course, upon the concession that the placenta is the source of the toxæmia. If this is granted, and there are many points in its favour to which I need not refer on this occasion, then Cæsarean section offers the safest method of conserving the lives of the mother and child. Eclampsia is a serious disease, and *general* statistics show that it is accompanied by a maternal mortality of from 20 to 30 per cent. The fœtal mortality is also high, about 39 per cent. The majority of cases of eclampsia occur in primiparæ before the onset of labour. The cervix is undilated, and if evacuation of the uterus is necessary and advisable the alternate modes of delivery are either accouchment forcé or vaginal Cæsarean section. Accouchment forcé is to be condemned. It is unscientific, and the results of the procedure are bad. Vaginal Cæsarean section, on the other hand, does not appear to offer the same advantages as the abdominal route. Access, especially in primiparæ, is not good, and consequently the operation is not so rapid. Added to which, there is liable to be more bruising of the soft parts and consequent risk of sepsis. There appears to be a special predisposition of the tissues to septic infection in cases of eclampsia, and for this reason the method of rapid delivery which is least liable to bruising and sepsis is best. The vagina is not so easily rendered sterile as the abdomen, in the emergency attached to any obstetric operation for eclampsia. For these reasons I believe the abdominal method to be the best route.

I am one of those who believe that rapid evacuation of the uterine contents is an all-important factor in the treatment of eclampsia, but I also believe that it should form the *earliest* method employed. Here I differ from the view generally held and advised by Dührssen and Bumm—viz., that it is inadvisable to empty the uterus by abdominal or vaginal Cæsarean section "after the first fit," as 75 per cent. recover without such operation. This figure, 75 per cent. of recoveries without operation, looks well, but what of the other 25 per cent.? Is not the first eclamptic convulsion the danger signal? If so, why delay and temporise with methods designed to combat the toxæmia already existing? Surely the ideal treatment is to remove at once the source of the toxæmia and then fight the latter with every available means. The Rotunda method of treatment by gastric and enterolavage combined with morphia and the administration of sodium bicarbonate is undoubtedly good, with a mortality of only 6 mothers in 74 cases, as published by Hastings Tweedy. Might it not be even better, however, if combined with immediate evacuation of the uterus upon the first indication of the disease? Dührssen and Zweifel have stated that improvement is greater in eclamptic patients after artificial than after spontaneous delivery. Is it not possible that in the latter the toxæmia is greater owing to the longer retention of toxic material?

The present general high mortality associated with eclampsia probably exists because treatment is not standardised and every man is a law unto himself. My own practice is to combine the Rotunda treatment with immediate evacuation of the uterus upon the first indication of the condition. If labour is not in progress and the cervix is undilated I always resort to Cæsarean section as being the most rapid and the safest method.

CONCLUSION.

In conclusion I may say that for the purpose of this paper I have referred to principles and not enumerated cases. As a matter of interest, however, I may state that on looking through my case-histories for the past 12 months I find that I have performed Cæsarean section upon 11 occasions. The indications were as follows:—

Indications.	Cases.	Maternal mortality.	Fœtal mortality.
Pelvic contraction: Flat pelvis	2	Nil.	Nil.
,, ,, Round ,,	5	,,	,,
Placenta prævia (central)	1	,,	,,
Eclampsia	3	,,	1

The maternal mortality was therefore nil, and one baby only was lost. This baby died upon the fifth day, and its death was due, I believe, to neglect upon the part of a nurse. Four of the cases of Cæsarean section were performed in the patients' own houses and as emergencies without any preparation, such as is the usual routine before a pre-arranged abdominal section. There was no mortality and no morbidity, which goes to prove that the operation may be performed with safety provided that adequate surgical principles are observed at the time.

There were two cases of maternal morbidity, both in nursing homes. One was a case of eclampsia in which the patient's doctor had ruptured the membranes before admission. The other was a case of flat pelvis, where intra-uterine sepsis occurred on the eighth day, in spite of the fact that no vaginal examination had been made prior to operation and the membranes were intact. In this instance the infection was traced to a nurse with a septic finger who was attending the patient. Both patients, however, recovered, and the morbidity cannot be attributed to the choice of the method of operation.

CEREBRO-SPINAL FEVER IN INFANTS AND YOUNG CHILDREN:

ITS TREATMENT AND AFTER-EFFECTS.

BY HELEN M. M. MACKAY, M.D. LOND., M.R.C.P.,
ASSISTANT PHYSICIAN, QUEEN'S HOSPITAL FOR CHILDREN;
BEIT MEMORIAL RESEARCH FELLOW.

EIGHT cases of cerebro-spinal meningitis in children under 8 years of age came under my care between September, 1916, and July, 1917. The series, though short, is, I think, one of considerable interest, and illustrates some of the main points with regard to this disease in young children.

Method of Treatment.

All these patients were treated by repeated lumbar puncture and the intrathecal injection of polyvalent antimeningococcal serum prepared by the Lister Institute. A general anæsthetic was rarely administered. There was not a single death, though some were very severe chronic cases of the posterior basic type.

The plan followed, speaking generally, was to continue the administration of serum daily until no meningococci could either be found in direct films or grown in culture from the cerebro-spinal fluid, and to continue lumbar puncture as long as th intrathecal pressure remained excessive. Exceptions to this plan of treatment are mentioned below The dose of serum given varied according to th quantity of fluid withdrawn and the intratheca pressure. As much as 20 c.cm. was given, in single dose, to an infant of four months.

The series is too short a one for any generalisations, but I attribute the recovery of these cases t two causes: (1) The efficacy of the serum administered, and (2) the large number of lumbar puncture performed.

Mortality and Sequelæ in Young Children.

Before the introduction of serum treatment th mortality in infants ranged, according to Flexne from 90 to 100 per cent.[1]; whereas F. E. Batten give the following figures for endemic posterior basi meningitis in London: "15 per cent. recover com pletely, 35 per cent. survive, but exhibit som permanent defect, either mental impairment, hem plegia, diplegia or blindness, while the remainin 50 per cent. prove fatal."[2]

Dr. Josephine Neal, in a series of 76 childre under one year treated with serum, had a mortalit of 50 per cent. Others record a mortality of fro 48·6 per cent. to 64·2 per cent.[1]

An adult who recovers seldom shows any pe manent after-effects of the illness,[3] but it is othe wise in young children, partly because they s frequently come under treatment late in the diseas on account of the not uncommon insidious onse and the difficulty in diagnosis, and partly becaus in their case the cranial capacity is not a fixe quantity, and therefore the increase in pressure i more gradual than in the adult.[4]

Necessity for Repeated Lumbar Puncture.

In chronic meningitis the intrathecal pressur appears to remain persistently high for a greate length of time than in acute cases; consequentl I believe it is absolutely necessary in most cases posterior basic meningitis to practise prolonge lumbar puncture in addition to the administratio of serum, although I am aware that variou authorities have stated that harm might resu from a large number of lumbar punctures.[5] If th is to be performed daily for many days, it is bes to dispense with a general anæsthetic wheneve possible on account of the disturbance to feedin thereby involved.

The cases given below have all been examine about two years after the attack of meningitis wit a view to ascertaining the after-effects, if any, le by the disease.

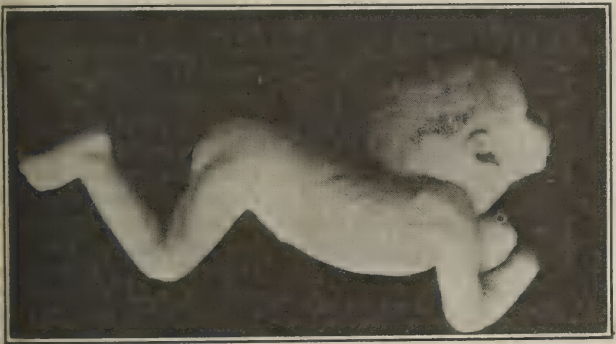
CASE 1.—Charles W., then aged 2 years 9 month was admitted to the Royal Free Hospital on Jan. 6t 1917, on the sixth day of his illness, and was a in-patient for 43 days. On admission he was we nourished, T. 101°, P. 92, unconscious, with gener rigidity and head retraction, herpes round the mout and furred dry tongue. The cerebro-spinal fluid wa turbid with a large deposit of polymorphonuclear pu cells and many intra- and extra-cellular mening cocci. Lumbar puncture was performed daily, with on exception, from the sixth to the twenty-third day illness, and again four times subsequently—20 lumba punctures in all. He was given seven doses of serum followed by the administration, commencing on th twenty-first day of illness, of an autogenous vaccine. lumbar puncture as late as the thirty-eighth day illness revealed a fluid which, though normal i character, was still under considerable pressure, but o the forty-second day only 2 c.cm. were withdrawn. Th temperature (excepting for a serum reaction from th twenty-fifth to the twenty-ninth days of illness), wa ractically normal after the fourth day in hospital. On scharge, the forty-eighth day after the onset of disease, e child was in a very drowsy, semi-stuporous, mental ate, and unable to sit up. His vision was apparently ormal, but he was, so far as could be ascertained, one deaf—he took no notice when a cab-whistle was own behind his back. I considered him one of the ilures of serum treatment, as I believed all mental velopment was likely to be arrested.

In July, 1919, he was seen again, when he was a well-veloped, intelligent, though shy child of 5 years old, ft. 9½ in. tall (average for age 3 ft. 5½ in.). He is not tually stone deaf, but for what he understands of the oken word he is apparently almost entirely dependent lip-reading, and is consequently, as his teacher ports, slightly backward in attainments for his age. iss E. Lowry, M.B., who kindly sent me a report on the r condition, says that the tympanic membranes are rmal in appearance. She was not able to ascertain her satisfaction what degree of bone conduction was esent, but it appeared to be fair. Mr. Malcolm epburn examined the boy's eyes, and reported that e appearance of the optic discs was normal (no record vision is possible).

It will be seen that in this case deafness (pre-umably a nerve deafness), is the only disability ft, yet in spite of this the child understands early all his mother says to him, and is himself le to talk, although it has been stated that below the age of 7 or 8 years permanent deafness sually leads to an associated mutism ; even though eech has begun it usually disappears."[6]

CASE 2.—Arthur M., then aged 8 months, was lmitted to the Royal Free Hospital on March 13th, 17, about three weeks after the onset of his illness, d was an in-patient for three months. On admission was absolutely unconscious, with general rigidity, ad lay in the typical attitude of head retraction with exion of all the joints of upper and lower limbs. trasbismus and inequality of pupils were present. The ild was fairly well nourished. The fontanelle barely lmitted the tip of the finger, and consequently anges in intra-cranial pressure could not be estimated palpation. Cerebro-spinal fluid was withdrawn nder considerable pressure ; it was slightly turbid and icroscopically showed polymorphonuclear cells and umerous meningococci, chiefly extra-cellular. Lumbar ncture and the injection of serum were performed daily r seven days, by which time meningococci had dis-opeared from the cerebro-spinal fluid. On the eighth y only 1 c.cm. of blood-stained fluid was withdrawn ery slowly, although lumbar puncture heretofore had vealed a fluid under pressure. The three subsequent mbar punctures were dry, and it was supposed that lhesions had developed preventing the outflow of fluid. ead retraction increased after admission till the ciput touched the back, strabismus was marked, and there was difficulty in swallowing and progressive wasting feeds by mouth were supplemented by nasal feeding for over six weeks. The temperature only once reached 100°, on the third day in hospital; on the whole it showed little variation from the normal. The photograph of the child shows his condition on about the fiftieth day of disease.

FIG. 1A.

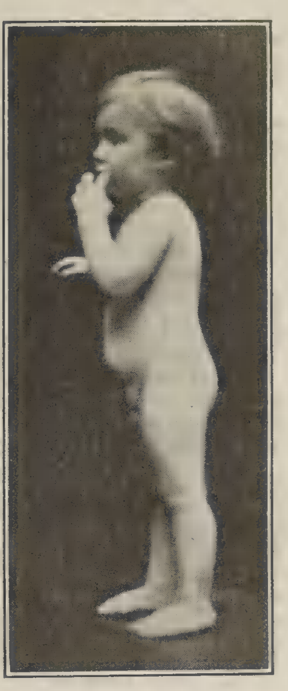


CASE 2 (Arthur M.).—Aged 9 months, about fiftieth day of illness. The wasting was much more marked than is apparent in this photograph.

After about four weeks in hospital spontaneous, though slow, improvement set in. Recovery was much delayed by an attack of diarrhœa and vomiting. Emaciation was extreme, his weight fell from 17 lb. 8 oz. to 11 lb. 14 oz. When he left hospital there was slight head retraction and he was not able to sit up in bed and took but little notice of his surroundings. However, six weeks later, at the age of 12 months, he was doing well in all respects ; all head retraction had disappeared, he was strong and gaining weight, and took took an interest in all he saw.

His mother gives the following account of his recovery. For some weeks at least after leaving hospital the child did not recognise her, but he steadily improved. He was clean in his habits at about 15 months. He began to talk at 18 months and spoke well at 2 years. He did not walk steadily however, until he was 2½ years old. He is now (July, 1919) 3 years 2 months old, is well developed for his age, and appears thoroughly intelligent. Hearing is normal, and apparently the only disability now present is some strabismus. Mr. Hepburn states that this condition appears to be due to an error of refraction, for which he has ordered glasses. The discs are rather pale, but there is nothing to indicate that this is a pathological, not a normal, pallor. (The mother states there was no squint before the attack of meningitis.)

FIG. 1B.



The same case aged 3 years 2 months. Physical and mental development normal —the only disability is a squint, stated by the mother to date from the meningitis.

It seems probable that this was not a true case of blockage of the outflow of fluid from the ventricles to the spinal canal, but that the failure to obtain fluid at subsequent lumbar punctures was due to hæmorrhage caused by pricking a vessel on the previous occasion. This is a not infrequent occurrence in young children. During convalescence as much as 30 c.cm. was withdrawn. This case also illustrates the very slight amount of pyrexia sometimes present in chronic cases.

CASE 3.—Ernest W., aged 4 years, was admitted to the Royal Free Hospital on March 26th, 1917, on the twenty-third day of his illness, and was an in-patient for nearly five months. On admission he was extremely wasted and white. The temperature varied from 97° to 102° F., the pulse was very poor, 120 to 168 or more. He lay on his side scarcely moving, head retracted, back arched, unconscious, and eyes half shut. His limbs, however, were flaccid. There was well-marked evidence of rickets with bowing of the legs. The cerebro-spinal fluid showed polymorphonuclear pus cells and isolated pairs of intracellular meningococci Twenty-five lumbar punctures were performed in all ; one daily till the fifteenth day after admission (thirty-eighth day of disease), and after that at longer intervals until the seventy-third day of disease. 30–60 c.cm. were generally withdrawn each time during the first 15 days, and as a rule 30–40 c.cm. at each of the subsequent lumbar punctures. The high intrathecal pressure persisted for over six weeks after the commencement of treatment—i.e., nine weeks from the onset of illness. Nine intrathecal doses of serum were given, and an autogenous vaccine was also injected. Cultures made from the fluid withdrawn on the forty-fourth day of disease grew a few colonies of meningococci after 48 hours' incubation, but the temperature was normal on the forty-fifth day, and, as no meningococci were found in the fluid from subsequent lumbar punctures, no more serum was given. The cerebro-spinal fluid, though still under increased pressure, was normal in character on the fifty-second day.

The course of the disease for about the first 80 days in hospital was thoroughly unsatisfactory. At first the child's general condition became steadily worse, and when the temperature became normal there was still no improvement. Emaciation was extreme, the pulse feeble, rapid and irregular, the head was retracted till the occiput touched the back, there was now great general rigidity, strabismus, and also incessant twitching of the face and of the right arm and leg for days on end. For 45 days nasal feeding was employed, at first to supplement nourishment by mouth, but for more than half that time it was the only method of feeding used as the patient was unable to swallow. On the eighty-eighth day after admission, 111th day of illness, he swallowed food again for the first time.

From about this time on he steadily improved; the twitching ceased, the rigidity and head retraction diminished, and nutrition improved. Concurrently the hairs on the trunk and limbs took on rapid growth, so that he was soon covered with quite a thick coat of hair, similar to that sometimes found in marasmic children, but much thicker than in any other case I have seen. After improvement set in a partial paralysis of the left side of the face became apparent. During the last few weeks of his stay in hospital the child would frequently scream, sometimes for several hours at a time, but apart from this he lay like a log in bed from morning to night, taking absolutely no notice of his surroundings.

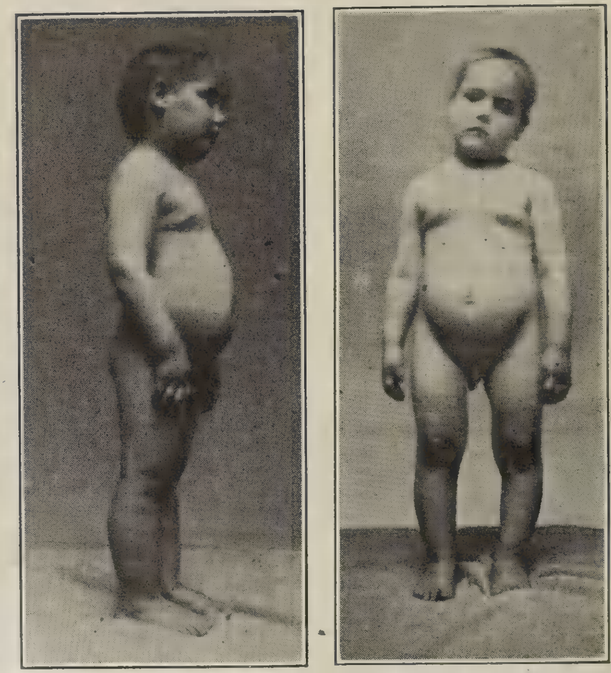


FIG. 2A. FIG. 2B.

CASE 3 (Ernest W.).—Aged 6 years 3 months. The photographs show the obesity (probably due to hypopituitarism resulting from meningitis), the tilting of the head to the left, and the rachitic bowing of the legs.

The history for the first six months after discharge is given by the mother: For about one week after going home he screamed constantly. Ten to fourteen days after discharge he pointed at something he wanted—this was the first sign of intelligence he gave. After this his mental faculties developed like those of an infant learning for the first time. One month after discharge he began to talk, two months later he was talking as well as before his illness "excepting for a stutter." He was clean in his habits from about the same date onwards. Five to six months after leaving hospital he could walk. Later he attended out-patients, and at that time he was enormously stout, presumably on account of insufficiency of the posterior lobe of the pituitary body due to the very chronic meningitis. He has now, July, 1919, entirely lost his thick coat of hair. He is still stout, though less so than before, his weight is 3 st. 11 lb. (average for a 6 year old, 3 st. 3 lb.), his height is 3 ft. 4½ in. (average for age, 3 ft. 8 in.). Hearing is normal; there is no obvious defect of sight. Mr. Hepburn reports "slight blurring of edge of disc above on temporal side, but nothing much; rest of disc normal."

He is a good-tempered child, stolid, and rather shy. A neighbour tells me he is quicker and more intelligent than a 5 year old adopted sister. He is certainly backward for his age (6 years 2 months). He cannot, for instance, count objects, although he can repeat his numbers correctly; but, on the other hand, he is capable of doing errands, and is occasionally successful in performing the "triple errand" of the Binet-Simon tests for a child of 7 years old. The day before he last attended his mother sent him to buy old potatoes, and the child recognised and refused to take new potatoes which were offered him in the shop. The paralysis of his face and the squint have disappeared, but he seldom uses the right hand and arm, which are slightly weaker than the left (probably now on account of want of use). He frequently carries his head not quite upright; the left ear is approximated to the left shoulder. The bowing of his legs noticed at the time of his admission to hospital is now extreme.

Like the first two cases described, this patient shows both the marvellous extent to which recovery may take place in an apparently hopeless case and also the persistence of high intrathecal pressure in chronic cases. If such a case were to come under my treatment now I should continue the administration of serum for a longer period. In this patient no organisms were found after the forty-fourth day of the disease, but as the intrathecal pressure remained high and improvement did not set in until after the 100th day it seems probable that meningococci persisted for some considerable time after the forty-fourth day, and were finally overcome by the resistance of the patient himself. Aaser grew meningococci from the cerebro-spinal fluid of a child with hydrocephalus more than two years and eight months after an attack of posterior basic meningitis at the age of 9 months, and he considers that hydrocephalus occurring after cerebro-spinal meningitis is really evidence of a chronic inflammatory process going on in the meninges.[7]

Treatment with pituitary extract has been commenced in the hope of improving his mental and physical development. As a rule, motor palsies disappear, as they have in this case.

CASE 4.—Mary S., aged 5 months, was admitted to the Royal Free Hospital on May 19th, 1917, about the tenth day of illness, and was an in-patient for over nine weeks. The onset of illness had been very insidious. On admission there was a bulging fontanelle, slight head retraction, and rigidity of the hamstrings. The temperature was 100·4° F. and the pulse 160. The patient was small for her age and weighed 9 lb. only. At the first lumbar puncture 7 c.cm. of blood-stained fluid was obtained containing meningococci, but after this little or no fluid could be obtained from the spinal canal (except on the seventeenth day of illness, when 10 c.cm. came out slowly), though lumbar puncture was attempted on ten occasions, the last shortly before the child's discharge. On the fourteenth day of illness head retraction was marked and bulging of the fontanelle extreme. Ventricle puncture was performed, and 35 c.cm. of slightly turbid fluid, containing great numbers of extra-cellular diplococci, was withdrawn, and 10 c.cm. of serum injected. On the sixteenth day 40 c.cm. of clear sterile fluid was withdrawn from the ventricle, and 10 c.cm. of serum injected. Next day 10 c.cm. was withdrawn by lumbar puncture as mentioned above, and 4 c.cm. of serum was injected. This was the last dose of serum given.

The temperature became normal about the nineteenth day of illness, but hydrocephalus steadily increased until there was very wide separation of the bones at the cranial sutures. Strabismus was marked, and there was much screaming, frequent vomiting, diarrhœa, and great wasting. 50 to 110 c.cm. of fluid was withdrawn at each subsequent ventricle puncture. Twenty-one ventricular punctures were performed in all, the left ventricle being tapped on each occasion, and the needle, so far as possible, passing through the same puncture hole and in the same direction with a view to causing as little damage as possible to the brain substance. After the last ventricular puncture, on the fifty-third day of illness, the puncture wound remained open, allowing a continuous escape of fluid in sufficient quantity to soak through a dressing of gauze and wool in a few hours' time. The wound did not heal for four or five days. The temperature for a few days was unsettled, but henceforth the fontanelle was level and no longer tense. The child began to improve, apparently as a result of the relieved pressure, and when discharged a fortnight later she was taking her feeds well, there was no vomiting, and she was gaining weight. Head retraction was still present.

This case was complicated by an effusion into the left knee-joint, and the knee was twice aspirated and turbid yellow fluid withdrawn. This was accompanied by pyrexia lasting about ten days.

The mother states that head retraction persisted for about two and a half months after discharge, and the child could not sit up unaided for about five months—i.e., until she was 1 year old. She did not walk well until 2½ years of age. For some months she was under treatment at St. Thomas's Hospital for rickets, and there seems little doubt that her backwardness in walking was largely due to this disease. When 1 year old she could say one or two words, but her progress in talking has been slow. On the other hand, she could sing "The Wearing of the Green" and one or two other songs with a good idea of tune before she was 2½ years of age.

When seen in September, 1919, when she was 2 years 9 months old, she would often pronounce a whole sentence clearly, though at other times she might repeatedly utter one of which not a single word was intelligible. She passed successfully nearly half the Binet-Simon tests for a child of 3 years of age. From the mother's account it appears that, though the child is now backward, her progress has been much more rapid since the improvement of the rachitic condition. Her physical development, including the shape of the head, is normal. The circumference of the head is 19¾ in., the normal for 3 years being 19 in. There was some enlargement of the radial epiphyses, and very marked bowing of the femora, the convexity forwards. Strabismus was still present. She generally fixed objects with the left eye. Ophthalmoscopic examination has not been made.

It may be interesting to compare with this a case recorded by Netter, in which chronic meningococcal meningitis in a child, aged 21 months, was complicated by blindness. Improvement in vision in this case coincided with the relief of intracranial pressure brought about by a lumbar-puncture wound remaining open and the fluid escaping into the tissues of the back.[8] Such cases suggest the possible benefit that might attach to the establishment of continuous slow drainage into the subcutaneous tissues by surgical means before permanent hydrocephalus is established. In cases where drainage is established by accident the risk of secondary infection must, of course, be considerable.

Cases of recovery after ventricular puncture are comparatively rare. Dr. Josephine Neal states that in her series of 76 cases of epidemic cerebro-spinal meningitis in children under 1 year 11 developed a block preventing the outflow of fluid from the ventricles, and 6 of these were treated by ventricular puncture, but all proved fatal. Another case treated by ventricular puncture recovered, but ther seems some doubt as to whether there was in this case a true block. As an indication of the danger of and the damage to brain substance which may result from ventricular puncture, this author quotes the case of a child of 7 months so treated, who at the age of 4 years was a helpless imbecile. But from the account given it would seem more probable that this condition resulted from the hydrocephalus itself.[1]

Fairley and Stewart also comment on unfavourable results obtained by ventricular puncture. "Ventricular puncture and decompression by trephining was performed in nine subacute or chronic cases with signs of internal hydrocephalus. All terminated fatally, but in several cases the patient's life was prolonged. It is noted that 3 out of 19 cases of internal hydrocephalus recovered spontaneously."[illegible]

The occurrence of a synovial effusion into the knee-joint in this case is of interest. I believe it is rare for the joint to be attacked in infants. Osler and Still state that a joint affection when it occurs in infants is generally periarticular, and, according to Rolleston, it is usually the joints of the hands and feet that are affected in infants.

CASE 5.—Stanley C., aged 4 months, was admitted to the Royal Free Hospital on June 28th, 1917, on the third day of his illness, and was an in-patient for 36 days. On admission he had a temperature of 104·2°, pulse 160, respiration 80, tense bulging fontanelle, very slight rigidity of the neck, and occasional twitching of the limbs. Lumbar puncture revealed a turbid fluid with many meningococci.

This case showed a recrudescence. The temperature remained practically normal from the eighth to the twelfth day in hospital, cocci had disappeared from the fluid and the administration of serum was stopped. From the thirteenth to the seventeenth day pyrexia was again present, and cocci reappeared in the fluid. Twenty lumbar punctures were performed, but four were dry. Thirteen doses of serum were given. Normal fluid was obtained under normal pressure on the twenty-first day. The child was discharged apparently recovered.

He was seen again in June, 1919, when he was 2 years and 4 months old. He now has severe rickets with much bowing of the legs. His weight is 1 st. 9 lb., instead of the normal 2 st. 1 lb. He learned to walk after the age of 2 years, and can now only say a few single-syllable words. He understands simple commands and appears fairly bright. He comes from a poor home, where there is often insufficient food, and is the eighth child of the family, of whom only one other is surviving, and it seems probable that his general backwardness is due to causes other than the meningitis.

In this case, as in Case 3, more serum appears to have been indicated at first. Possibly it would be a safe rule always to give at least two doses of serum after meningococci have ceased to be found in the cerebro-spinal fluid, as thereby one might lessen the chance of a recrudescence, which presumably is always due to the survival of a few organisms in some part of the central nervous system.

Case 6.—James D., aged 4 months, was admitted to the South Western Hospital, Stockwell, on Sept. 24th, 1916, and was an in-patient for 57 days. He was certified as a case of scarlet fever, and had a history of four days' malaise. On admission there was nothing to suggest scarlet fever, excepting a flushed skin and slight pyrexia. There was constipation, but no vomiting or rigidity of the muscles of the neck or limbs, and the fontanelle was level. On the tenth day of illness the child lay with his head slightly retracted, and next day, though tension at the fontanelle was still normal, there was in addition slight rigidity of the cervical muscles and hamstrings. Lumbar puncture was performed (eleventh day of illness); 6 c.cm. of turbid fluid were withdrawn under normal pressure, and the same quantity of serum was injected. A very few intra- and extra-cellular meningococci were found in the fluid. The fontanelle was not tense at any stage of the illness. Ten successful lumbar punctures were performed (on several occasions no fluid could be obtained), and seven doses of serum given, the last on the twenty-fifth day of illness. Latterly, the child appeared to be growing worse in spite of the serum and consequently no more was given, although meningococci were found in the fluid withdrawn on the thirty-first day. About this stage diarrhœa supervened and rendered the outlook still more unfavourable. On the thirty-fourth day the injection of vaccine was begun. Three different vaccines, prepared from three different strains (type unknown) were given, one dose of each, followed up by an autogenous vaccine. On the thirty-sixth day the fluid appeared practically normal, although the child's condition was growing worse, and two days later there was present the so-called "undulating type" of respiration (respiration resembling the Cheyne-Stokes type, except that no periods of complete apnœa occur), and the pulse was very feeble, although the fontanelle remained level. However, from the fortieth day onward improvement was steady and rapid, and on the forty-ninth day all rigidity had disappeared, and the child was obviously thriving.

The boy's general development, mental and physical, is now (September, 1919) excellent. He began to walk before he was 1 year old and to talk at about 1½ years, and is a bright, intelligent little chap of 3.

This case is of interest for several reasons: (1) It came under observation early, apparently during the pre-meningitis stage, but was not diagnosed until the eleventh day of illness, the first day on which there was any rigidity of the cervical muscles. It is a good illustration of the difficulty of early diagnosis in infants. (2) It was atypical in that throughout there was no obvious increase in intracranial pressure—I believe a very unusual phenomenon. Dr. Neal reports absence of a bulging fontanelle in 5 out of 76 cases.[1] (3) Serum treatment with the Lister polyvalent serum produced no visible improvement; very possibly the strain of meningococci was different from that present in the other cases. Unfortunately, the type was not ascertained in any case belonging to this series. (4) The child abruptly began to improve on the fortieth day (although undulating respiration had supervened), just before the injection of the first dose of autogenous vaccine, possibly, of course, as a result of the strain of organisms in the third dose of stock vaccine. (5) Improvement, when it began, was much more rapid than in mos of the cases of the series in whom treatment wa commenced late. Possibly the rapid improvemen was associated with the previous absence o increased intracranial tension.

Case 7.—Ernest S., aged 7 years, was admitted to th Royal Free Hospital on March 17th, 1917, on the secon day of illness, and was an in-patient for about fiv weeks. The onset of the disease was sudden, accompanied by vomiting and convulsions, and on admissio he was semi-conscious and presented a typical pictur of cerebro-spinal meningitis, with marked head retraction. He had herpes on the lips and developed similar eruption on the cheek and forefinger. N organisms were found in the direct films, but mening cocci were grown in culture. Ten lumbar puncture were performed and nine doses of serum were give The patient was rational, and fluid was sterile an nearly clear on the sixth day of illness, but, as th temperature had not settled, treatment was continue for a few days longer. A serum rash appeared on th eleventh day. Rigidity of the neck had almost dis appeared by that time, and he made an uninterrupte recovery. He is now 10 years old, and his teache states that his intelligence is normal for his age.

Miss Lowry reports that he has very slight deafness the middle-ear type. He has adenoids and the righ tympanic membrane is scarred. His mother says tha after discharge he complained of headache, and sti does so at times. It is hoped that the early removal his adenoids will cure the headache.

This case presents a fairly typical picture cerebro-spinal meningitis in an older child at a age when early diagnosis is as a rule much easie and shows the increased rapidity of recover usually consequent on early treatment.

Case 8.—John J., aged 7 years. This case shoul perhaps, not be included in the series, as, although or or two pairs of diplococci were found in direct filn made from the slightly blood-stained fluid obtained the first lumbar puncture, no meningococci were grow in cultures. However, he had meningismus accom panied by well-marked optic neuritis, and made a uninterrupted recovery under treatment with lumba puncture and intra-thecal administration of ant meningococcal serum. Many observers record a sma percentage of cases which are almost certainly cases meningococcal meningitis, but in which the diagnos has not been clinched by growing the organisms fro the cerebro-spinal fluid, and consequently I inclu this case, though I recognise that the diagnosis is op to doubt.

This child is now (July, 1919) a quick, healthy-looki boy of 10, and Mr. Hepburn reports: "Vision in ea eye 6/6, discs perfectly normal and a good colour a well defined." It was not possible to test his field vision. Different observers have placed the inciden of optic neuritis at very different figures. Rollest states that it is usually regarded as infrequent, a that it is especially related to the septicæmic type infection,[10] whereas Fairley and Stewart place it 41 per cent.[11]

Conclusions.

The knowledge which I, personally, have deriv from following up these patients is that no matt how hopeless a chronic case of cerebro-spin meningitis may seem, the patient may with adequa treatment make a complete, or almost complet recovery. So far as can be judged at present, a the children described above should develop in useful members of society. I ascribe these go results largely, as already stated, to the continuan of lumbar puncture as long as the intrathec pressure remained excessive.

To summarise results. Of the 8 cases, 5 (Cas 1, 2, 6, 7, and 8) are now healthy, well-develop children with normal mental faculties, althou suffer from a disability—i.e., deafness (Case 1) d strabismus, stated by the mother to date from e meningitis (Case 2). As an indication of the verity of the disease in Case 1 it will be remem- red that as late as the forty-eighth day he was still mi-stuporous and unable to sit up. The same int is illustrated in Case 2 by the photograph d the fact that he required nasal feeding for over x weeks. Case 6 was also a severe chronic case, t in this instance the intrathecal pressure was ver high.

The three remaining patients (Cases 3, 4, and 5) e mentally backward, but it is difficult to say to hat extent this is due to the rachitic condition om which they have all suffered. In Case 5 both e physical and mental backwardness may, I lieve, be wholly ascribed to rickets, whereas th diseases were probably factors in the produc- on of the present mental condition of the other vo cases. In Case 3 treatment was not begun ntil the twenty-third day, the child was unable swallow for over three weeks, and at the end of ve months in hospital he appeared demented, yet ow the only after-effects are some backwardness, diposity, and a very slight localised muscular weak- ess, probably now merely the result of disuse. In ase 4 there was internal hydrocephalus and l ventricular punctures were performed, but the nly after-effects now apparent are some back- ardness and strabismus.

I regret that I have not had the opportunity of sting this method of treatment sufficiently often obtain statistics thereon, and it is, of course, npossible to generalise from such a small number f cases, but in view of the striking recoveries escribed above it would seem worth while giving rolonged lumbar puncture (in addition, of course, the administration of anti-meningococcal serum) more extensive trial in chronic cases with a ersistently high intracranial tension, as, though oubtless practised by some, it is not, I think, the ethod of treatment in general use.

Permission to publish the cases was kindly given y Dr. Foord Caiger, Dr. J. W. Carr, Dr. Hazel hodak, Dr. A. Phear, and Dr. P. W. Saunders, nder whose charge the patients were admitted to ospital. I should also like to express my indebted- ess to Mr. Hepburn for his kindness in examining he children's eyes; to Dr. Eleanor Lowry, who xamined the ears; to Dr. Mary Schofield, and Dr. athleen Armstrong, who carried out the examina- ion of the cerebro-spinal fluid; to Dr. Nora Crow, ho spent much time and trouble in obtaining the hotographs illustrating this paper; and to Dr. hodak, who has very kindly assisted me in ollowing up Case 4, which was admitted to the oyal Free Hospital under her charge. My special hanks are also due to Dr. J. W. Carr, who was, I elieve, the first to point out the relationship etween the posterior basic meningitis of infants nd epidemic meningitis,[12] for his encouragement, nd the interest he has shown in this investigation.

ŒDEMA AS A SYMPTOM IN SO-CALLED FOOD-DEFICIENCY DISEASES.

BY A. DOUGLAS BIGLAND, B.A., M.D., M.R.C.P.,
HONORARY CAPTAIN, R.A.M.C.; HONORARY PHYSICIAN, DAVID LEWIS NORTHERN HOSPITAL, LIVERPOOL; LECTURER IN CLINICAL MEDICINE, UNIVERSITY OF LIVERPOOL.

THROUGHOUT the whole world, at different times and in many diverse places, epidemics have broken out, having as their main feature a more or less extensive dropsy. As might be supposed, these epidemics occurring so diffusely have been described independently by many observers. Having observed one such epidemic on a small scale, it appeared to me that a correlation might be made between this and other similar outbreaks with the view to determining, if possible, a common ætiological factor, or, at least, to make a short comparative study of such conditions.

It is proposed first to give a brief account of the various epidemics, and then discuss their possible common origin.

I. *Œdema occurring in Turkish Prisoners of War in Egypt.*

In August, 1916, I was appointed one of the medical officers at a prisoner of war hospital in Cairo. The prisoners consisted mainly of Turks with a sprinkling of Arabs. Some of them were admitted direct from the various fronts where they had been captured, while others had been stationed for a longer or shorter period in one or other of the big prison camps in the Cairo district.

Almost immediately certain outstanding features among a proportion of the cases presented themselves. 1. Certain cases died apparently from dysentery, which when examined post mortem revealed very slight intestinal lesions; cases which, in the vivid language of the fifth year medical student, should not have died. So marked was this that one had recourse to a metaphysical explanation based upon Mahomedan ideals and the fatalism of the East. 2. The great emaciation presented by some of the patients resembling nothing so much as the appalling pictures indelibly associated in one's mind with Indian famines. 3. The extraordinary degree of anæmia noticed especially in malarial cases. Some of these had a red cell count of only a little above 1,000,000 and a very low hæmoglobin percentage. 4. The presence of œdema varying from a slight pitting about the shins to a condition of general anasarca involving all the serous cavities.

It was supposed after further observation that these striking facts could be explained on the assumption that we were dealing with ordinary tropical pictures of disease aggravated by a common factor underlying them all. The above conditions having been brought to the notice of the headquarters staff, Brevet Major P. Manson-Bahr was detailed to study the matter. In this work I assisted him.

It was found that a few of the cases were suffering from malignant malaria, but the cachexia was so extreme that one felt that this was not the only cause. Then it was thought for some time that beri-beri might be the true diagnosis. In fact, certain observers diagnosed the cases as such. But upon further observation it was found that there were no heart symptoms and that there was no definite neuritis. It is true that some of the cases presented absence of knee-jerks, but this could be explained by the general asthenia. Also the vague pains and tenderness in the legs noted from time to time were in all probability of psychic origin. In fact, the condition only resembled beri-beri in the presence of œdema. It was remarked at the time that the only known clinical picture resembling this was that of so-called "epidemic dropsy" described in India.

In the autumn of 1916 pellagra was first noticed among the Turkish prisoners. Immediately on this discovery it was felt that the œdema must have some food deficiency as its explanation. This will be referred to later in the general discussion.

I have full notes on 24 of the œdema cases before the outbreak of pellagra. The main features are set out as follows:—

I. *Extent of the Œdema.*

General anasarca, including serous cavities	8	Legs and face	4
Feet and legs	11	Legs and sacral region	1

II. *Previous Dysentery or Malaria.*

Malaria only	3	Both malaria and dysentery	8
Dysentery only	10	Neither malaria nor dysentery	3

III. *Anæmia.*

R.B.C. 1,500,000 and below ...	4	Anæmia nil or slight	17
R.B.C. 1,500,000–2,500,000 ...	3		

IV. *Variation in Knee-jerks.*

Normal	16	Sluggish	3	Absent	5

Of these 24 cases 8 died, the remainder being discharged from hospital as cured. Later it was attempted to trace these 16 "cures" with the view to seeing how many had developed pellagra. All could not be found, but 4 had developed in the meantime true pellagra.

Post-mortem examinations were performed on the 8 fatal cases (for three of these I am indebted to Major Manson-Bahr). The results may be summarised as follows: Bacillary dysentery lesions in the intestines were present in all 8 cases. Ascites was noticed in 5, pleural effusion in 3, and pericardial effusion in 1 case. All the organs appeared small; the heart showed the condition known as "brown atrophy" in 7 of the cases. Only in 1 was there a fatty liver; in others this organ was small. Tuberculous bronchial glands were present in 2 cases.

Œdema has not hitherto been recorded as a clinical feature of pellagra, so it is fitting that the following facts concerning its incidence in these cases should be noted. 64 cases of true pellagra were studied from many aspects; it is only my intention here to deal with the one symptom—œdema.

V. *Incidence of Œdema in Pellagra Cases.*

Œdema observed	36	No œdema observed or mentioned in history	21
Œdema in history only	7		

VI. *Extent of the Œdema* (36 cases).

General anasarca	7	Legs and face	0
Legs and feet	29	Legs and sacral region	0

VII. *Incidence of Previous Malaria and Dysentery.*

Malaria only	1	Neither malaria nor dysentery	30
Dysentery only	25		
Malaria and dysentery	8		

VIII. *Time Relations between Onset of Œdema and Pellagrous Skin Manifestations.*

Total pellagrins with œdema	43	Œdema synchronous with rash	15
Œdema before rash	24	Œdema after rash	4

Careful blood counts were made on 25 cases:—

IX. *Blood Pictures.*

R.B.C. 1,500,000 and below ...	2	R.B.C. up to 3,500,000	9
R.B.C. up to 2,500,000	2	R.B.C. above 3,500,000	12

The absolute leucocyte count in the majority approximated to normal, but a relative lymphocytosis was present in some. Of the 25 cases, 17 had a lymphocytosis of over 30 per cent. and 10 over 40 per cent.; the highest count was 60 per cent. Eosinophile cells showed on the average 1·5 per cent., the highest count being 6 per cent. The colour index in 14 of the cases was normal, in 5 below 1 and in 6 higher than 1. No organic disease of the heart, no kidney disease, no marked diuresis, and no bradycardia were observed in these cases. Diarrhœa, of course, was common to all, and the blood pressure of the pellagra patients was found to be very low. Of these 64 pellagra cases, 25 died.

This, then, is a brief account of the œdema epidemic as it occurred among Turkish prisoners of war during the autumn, winter, and spring of the years 1916–17. The question of pellagra itself will be dealt with in a subsequent paper.

II. *War Œdema in Europe.*

This condition was first observed in January, 1917, among prisoners of war camps and in large towns throughout Germany. Its onset was apparently sudden, with œdema occurring as a rule in the feet and legs, but occasionally in the thighs and trunk. In more than one-half some degree of facial swelling was noticed; in one-sixth there was œdema of the hands, and in one-ninth ascites was also present. There were no cardiac symptoms, except marked slowing of the pulse, and the urine contained no albumin. The blood showed a reduction in R.B.C. of from one to two million. Diarrhœa was fairly common. It appears that as soon as the patient was put to bed a marked diuresis occurred and the œdema rapidly disappeared. Remissions and recurrences were fairly common.

War œdema then appeared in Vienna with great suddenness. Schiff[1] drew attention to the similarity of this condition and beri-beri and other diseases depending upon a failure of vitamines. Baucke[2] described a series of cases where the œdema was only on the face, and in extreme cases on the neck and backs of the hands. This he attributes to the sun's rays, which were very intense at the time. Bradycardia again was a pronounced feature.

Schittenhelm and Schlecht[3] observed more than 200 cases of war œdema in men from 19 to 33 years of age. In these bradycardia was associated with an extremely low blood pressure. All the men were in a state of malnutrition, as shown by complete absence of fat and a considerable reduction of albumin, as shown by the very low concentration of the serum on refractometric examination of the blood.

The disease was then remarked in the reconquered Italian territory. Cases were described by Pighini.[4] No men in the prime of life were affected, and the food conditions were very bad.

In Bohemia the condition was studied by von Jaksch.[5] In 1917 "hunger œdema" was discovered in 22,842 persons, of whom 1028 died. He found in the blood a lymphocytosis to be not uncommon. Jansen[6] found that R.B.C. varied from 1·5–4 millions, that the colour index was often higher than 1, and that there was a relative lymphocytosis of 30–55 per cent.

His[7] has noted that war œdema occurred in Turkey among starving persons and convalescents, and also as an independent disease.

Another very important point observed in some of the cases was the presence of certain skin manifestations. Petenyi,[8] working at Budapest, in 106 cases found only 3 with normal skins. In all the rest the skin was extremely dry, and presented more or less considerable desquamation. Reach[9] noticed much pigmentation of the scrotum in his cases.

As regards the ætiology of war œdema many explanations have been advanced. It appears that men were more affected than women, and young children not at all. By far the most accepted explanation of the condition is one based upon a food-deficiency factor. Some workers regard previous dysentery, typhus, relapsing fever, and tuberculosis as a cause, but such are in a small minority. Von Jaksch[5] states that the disease appears whenever the calories in the diet fall below 1400, and that a deficiency of carbohydrates and fat is the cause. In August, 1917, when the affected districts received an adequate supply of potatoes war œdema began to diminish. Most workers agree to a great diminution of albumin in the body in this disease, together with marked wasting of all the organs, including endocrine organs, in post-mortem examinations.

Regarding the actual cause of the œdema itself two theories are brought forward: (1) that toxic products of albuminoid metabolism may damage the endothelial lining of the blood-vessels, and so cause œdema; or (2) that it is due to a calcium deficiency which apparently increases the permeability of the vessel wall.

III. *Epidemic Dropsy.*

This condition was first described in India during the cold season of 1877–78. In the following summer it disappeared, but broke out again in the cold season of 1878–79. This second outbreak was spread over a wider area, the first having been observed only in the region of Calcutta. Again, in the cold months of 1879–80 the epidemic was observed, and this time over a still wider area. It vanished during the hot weather of 1880. About the same time isolated outbreaks occurred elsewhere in India and a similar condition appeared in Mauritius.

Apparently the subject was then forgotten, and no further outbreaks were recorded for 20 years. In 1901 cases of epidemic dropsy again made their appearance in Northern Calcutta. These were pronounced to be the same as had occurred in previous epidemics. In 1902 there was an outbreak in Bengal, and again another in Calcutta in 1908–09. This last was fully reported upon by Major Greig,[10] to whose careful observations much of the present note is due.

The initial symptoms are pyrexia, gastro-intestinal disturbances, paræsthesiæ, and deep-seated pains throughout the body. Dropsy was an initial, or, at all events, an early symptom. It was noticed chiefly in the lower limbs, occasionally in the arms, body, and serous cavities, and rarely in the face. Vomiting and diarrhœa were common early symptoms, and dysentery sometimes occurred during the course of the disease. In a considerable proportion of the cases, according to Macleod,[11] the skin surfaces became erythematous or affected with an urticarial, scarlatinal, or morbiliform rash. Eczema, desquamation, and excoriation were sometimes observed later. Anæmia was a constant feature, so much so that in Mauritius the disease was known as "acute anæmic dropsy." Greig[10*] and Megaw[12] found an increase in the lymphocytes, both relative and absolute.

Greig, in his conclusions on the Calcutta outbreak in 1908–09, states:—

> 1. That no causa morbi is to be found in the blood, œdematous fluid, excreta, &c. of epidemic dropsy cases.
> 2. That the features of epidemic dropsy very closely resemble those of "ship beri-beri."
> 3. That the evidence points to epidemic dropsy being non-infectious.
> 4. That there is evidence to show that epidemic dropsy is a nutritional disease, and is brought about by a one-sided dietary.
> 5. That the two severe outbreaks of epidemic dropsy in Calcutta and Bengal ...... have been correlated with a sustained high price of food grains during the period, and the cessation of these epidemics has synchronised with the fall in the price of food.

IV. *Ship Beri-beri and Scurvy.*

Ship beri-beri might be described as beri-beri without neuritis. Thus Nocht,[13] working in Hamburg, and the Norwegian Ship Beri-beri Committee,[14] state that symptoms of neuritis of the limbs are comparatively rare. Nocht only found neuritis in 4 of his 34 beri-beri ships, while the Committee only observed it in 4 out of 57 ships. Holst[15] agrees with Nocht that ship beri-beri is a food disease "showing a marked congruence with scurvy."

After the occupation of Rangoon in 1826 Waddell[16] noticed that the troops were affected with scurvy. He wrote: "In all the worst cases the feet became œdematous, and however apparently mild the other symptoms might have been, this affection was an almost certain prognostic of approaching anasarca, hydrothorax, and death." He also adds that diarrhœa was a common symptom in these cases.

Norman Chevers[17] apparently also was acquainted with a malady similar to epidemic dropsy and the above conditions. To this disease he gave the name "Morbus Bengalensis." He describes it thus: "Throughout his daily work, the powerful influence of this condition of chronic semi-starvation, not merely in the poor Bengali himself but throughout his entire race and generation, is constantly obtruding itself upon the physician who says: 'This man's constitutional malady is malnutrition, anæmia, asthenia, complicated with fever, dysentery or what not.'" As Greig well says: "If we replace Chevers's 'what not' with the symptoms swelling of the feet and breathlessless, a fairly complete description of the features of epidemic dropsy results."

V. *Œdema in East Africa.*

This section of the paper is supplied by E. S. Stubbs (M.D., Ch.B., B.Sc., late Capt., R.A.M.C.). Unfortunately, his important communication is somewhat long, so I have taken the liberty of abstracting it. He describes a condition diagnosed beri-beri which was prevalent among native troops in Jubaland (on the northern border of British East Africa). The diet of these troops had been at times without fresh food, and consisted chiefly of polished rice. In 1917 a paper on cases of beri-beri in a barrier hospital in German East Africa was circulated, but apparently the general opinion was that the disease was ankylostomiasis and not beri-beri at all. Captain Stubbs met a medical officer who was himself convalescent from the disease.

Apparently, among European troops in East Africa there were no cases of unexplained œdema except the above-mentioned cases of so-called beri-beri. "Most of my work," writes Captain Stubbs, "was with native carriers, chiefly Kavirondos and Kikuyus. I was at once struck by the great number of cases showing anæmia and persistent œdema of gradual onset. Examination of the urine often showed albumin, sometimes a trace, sometimes a large quantity. I came to consider that the great majority of these cases were ankylostomiasis." The reasons adduced for this conclusion may be summarised as follows: (1) The great amount of ankylostome infection present as gauged by stool examinations and by post-mortem findings; (2) most of the patients, though not all, improved considerably under anthelmintic treatment. The arguments against a food deficiency disease (beri-beri) were: (1) The diet which the patients had been enjoying for some weeks was regarded as sufficient to make good any former deficiency; (2) neuritis was not a prominent symptom, though the complaint of pains in the limbs, especially at night, was very common.

When shown photographs of pellagrins Captain Stubbs stated that the appearances did not seem unfamiliar to him, though he would not like to lay too much stress on this point. He concludes his remarks as follows: "The outstanding fact in the East African native hospitals was this, the death-rate was high. For months in 1917 there were 8–25 deaths a day in 1000-bedded hospitals. Yet in the majority of these cases there was no dramatic illness to account for death, unless it might be a terminal broncho-pneumonia. The patients commonly had no raised temperature and no definite dysentery, just a chronic diarrhœa of perhaps three to four motions a day. They were usually very anæmic, and frequently had œdema of the feet. Their food did them no good; they became emaciated and died. We regarded the deaths as due to chronic dysentery and helminth infection, especially ankylostomiasis; often they were the subjects of chronic malaria as well. Post mortem frequently chronic ulceration of both bacillary and amœbic types were seen. Another feature was the presence of excess of fluid in the pericardium and pleural cavities, with which there was associated a remarkable smallness of the heart and kidneys."

Factors in Causation.

Having now described the diverse epidemics in which dropsy was the prominent symptom, there yet remains the task of elucidating, or at any rate correlating, the facts disclosed. I propose to discuss the various factors that have been mentioned from time to time as causing the above conditions.

1. *Malaria.*—Manson,[18] when discussing malarial cachexia, says: "As a consequence of defective nutrition from prolonged anæmia and recurring fever, the muscular tissue of the heart in chronic malaria may degenerate, the ventricles dilate, and in time the lower extremities become œdematous." Hulse[19] is of opinion that epidemic dropsy is nothing but malarial cachexia.

Against this view I advance the following arguments. Malaria was not mentioned by other observers as a causative factor, and yet the picture of malarial cachexia must have been an extremely common one to most, especially the workers in India. To my mind, it is inconceivable that this should have been overlooked, were it indeed present. It is not probable that the outbreaks of epidemic dropsy in German towns, for example, were due to such a factor. Again, not all the cases had anæmia, which is a constant in malarial cachexia. Moreover, I have notes of five cases of severe malaria anæmia who never showed any œdema whatever. I append their blood counts:—

Case 1:	Hb. 50 per cent.:	R.B.C., 1,500,000.
,, 2:	Hb. 70 ,,	R.B.C., 2,800,000.
,, 3:	Hb. 60 ,,	R.B.C., 1,500,000.
,, 4:	Hb. 60 ,,	R.B.C., 1,400,000.
,, 5:	Hb. 60 ,,	R.B.C., 1,700,000.

Again, in my own series of cases it will be seen that of the 24 dropsy cases only 11 showed evidences of malaria, and out of 64 pellagrins only 9. It should be stated here that malaria was diagnosed in the fatal cases by the post-mortem appearances of the spleen and their clinical condition before death, while in the living the diagnosis depended upon blood examinations, presence of excess of large mononuclear cells, and from typical attacks of pyrexia, &c. In my opinion, therefore, some of the cases of œdema may have been due to malarial cachexia, but the majority were not.

2. *Dysentery.*—This condition is very much more difficult to exclude than malaria, for the reason of its extreme frequence in connexion with epidemic dropsy. As far as one can see in all the epidemics throughout the world gastro-intestinal symptoms of all grades of severity were almost constantly associated with the œdema.

In my own series of 24 dropsy cases 18 had dysentery, and of 64 pellagrins 33 showed evidence of the condition. The majority of them were of the bacillary type. In Manson's book on Tropical Medicine I can find no reference to œdema as a sequel of either type of dysentery, though Davidson[20] mentions dropsy of the legs as a result of the disease. It will be granted, I think, that this statement is not tantamount to saying that epidemic dropsy outbreaks are caused by dysentery, at most it is an association only. The reason of this coincidence can be explained in three possible ways: (1) Epidemic dropsy occurs frequently in those places where dysentery is also common; (2) both diseases are associated with periods of food stress, as, for example, during wars and famines; (3) if a man who has been starved, at any rate as regards certain articles of food, then develops dysentery, his system is immediately drained of most of its nourishment, and at the same time he is starved in hospital for therapeutic reasons. At first he was only a candidate for one of the food deficiency diseases; now he is fully qualified. That epidemic dropsy and dysentery are associated cannot be denied, but that the latter is the cause of the former is not proven.

3. *Scurvy.*—Except in ship beri-beri this disease appears to be a rare event in epidemic dropsy. In the Cairo cases I have notes of two prisoners who had bleeding gums, but it is doubtful whether they were really suffering from scurvy at all. In any case neither of them showed any œdema. It is only fair to state, however, that the late Colonel F. M. Sandwith, when he came to visit the Prisoners of War Hospital in Cairo, was of the opinion that the œdema was scorbutic in origin. With every respect to the memory of this great worker I must say that I could find no evidence whatever for his statement.

4. *Ankylostomiasis.*—It is evident that Captain Stubbs, in his observations on the East African outbreak, is of the opinion that his cases of epidemic dropsy had ankylostome infection as an ætiological factor. Possibly in his cases this was true, but in the majority of outbreaks no mention of intestinal parasites is made. In my own cases not one showed evidence of ankylostomiasis, though the worms in post-mortem cases and the ova in the stools of the living were searched for repeatedly with every care. The absence of eosinophilia in these cases also is against such an infection. I think it may be truly said that in the vast majority of cases ankylostomiasis is not the cause of epidemic dropsy.

5. *Beri-beri.*—Without doubt throughout the world, even by experienced observers, the diagnosis of beri-beri has been confused with that of epidemic dropsy. The class of person commonly

attacked and the associated œdema are facts which apparently lead many into the trap. In my opinion, the absence of true neuritis and the comparative rarity of heart attacks in epidemic dropsy should point to a true diagnosis. That the two diseases are related may be allowed, but that they are separate clinical entities, so far as our present knowledge goes, is practically certain.

6. *Epidemic dropsy a food-deficiency disease.*—There yet remains the discussion as to whether epidemic dropsy is not, after all, a food-deficiency disease. Before dealing with this section I should like to make it quite clear that I regard all the above-described epidemics as similar in constitution and origin. Of so much there can be no doubt. When we consider the œdema, and the absence of renal or cardiac causes to explain it; when we notice the absence of neuritis, the presence of diarrhœa, emaciation, anæmia, and relative lymphocytosis; when we find the curious wasting of all the organs post mortem and try to explain the seemingly causeless deaths, we must be struck by the fact that we are here dealing with a definite clinical entity. As in clinical signs and symptoms so in outward circumstances do we notice the same similarity. Whenever there are wars, famines, and long voyages in ill-equipped ships; wherever persons are housed together under relatively bad conditions, as in asylums and prisons; wherever the population lives on a minimal or one-sided dietary liable at times to be reduced to a fraction above nothing, there we have the conditions for the development of food-deficiency diseases and there we have epidemic dropsy.

Epidemic dropsy and pellagra.—Two matters alone remain for discussion. Firstly the relation between epidemic dropsy and pellagra. To the best of my knowledge, in none of the epidemics of pellagra was œdema mentioned as a symptom of the disease. In Italy pellagra has decreased to a remarkable extent, while epidemic dropsy has made its appearance. Among Turkish prisoners of war in Egypt the pellagra epidemic was preceded by the epidemic of œdema, and even the pellagrins themselves in many cases showed dropsical symptoms. The presence of skin eruptions in some cases of war œdema in Europe is of great interest in this connexion. When I examined the Armenian refugees at Port Said, many months after the pellagra outbreak there had ceased, I was unable to find any "relics" of the disease at all until I happened upon a girl with marked œdema of the legs; on looking up the records I found that she had had pellagra in the last outbreak. Frequently, while in Egypt, I said to myself, "Europe will be full of pellagra." As a matter of fact, it was full of war œdema.

The Mechanism of Œdema Production.

The second matter requiring attention is the exact mechanism of œdema production in these cases. I mention three possible explanations. 1. In cases that die of epidemic dropsy there is found marked wasting of all the organs, even of the heart. The individual in such cases must have been living on his own body protein. It is suggested that toxic products of albuminoid metabolism damage the endothelial linings of the vessels, thus giving rise to œdema. 2. That the œdema is due to a deficiency in calcium salts. 3. Recently much attention has been directed to the effects of starvation on the ductless glands or endocrine organs. The Committee of Inquiry into Pellagra among Turkish Prisoners of War in Egypt[21] advanced the theory that many of the symptoms of pellagra are due to adrenal insufficiency. The close similarity between this and Addison's disease is certainly evidence in favour of the theory. More recently most interesting work has been done by McCarrison[22] on the pathogenesis of deficiency disease. By starving birds and also by feeding them on vitamine-free diets he found a similar result—viz., that all the endocrine organs atrophied except two: the pituitary remained the normal size, while the suprarenals were markedly hypertrophied. Some of the birds showed symptoms closely resembling those of war œdema. McCarrison states that "œdema has invariably (100 per cent.) been associated with great hypertrophy of the adrenal glands; 86 per cent. of all cases having great hypertrophy of these organs had œdema in some form." Again, "the œdema of inanition and of beri-beri is believed to be initiated by the increased intracapillary pressure which results from the increased production of adrenalin, acting in association with malnutrition of the tissues." In passing it is interesting to note that "œdema of the auriculo-ventricular junction" was found in these cases. This may be a possible explanation of the bradycardia in some of the war œdema cases.

It is conceivable, therefore, from the above considerations that epidemic dropsy is a condition due to affection of the suprarenal glands as a result of inanition arising from starvation, complete or partial. It may be that the suprarenals hypertrophy at the expense of the other endocrine organs, and by their increased function give rise to dropsy. Possibly, also, this hyperactivity may in time give place to a suprarenal insufficiency as exophthalmic goitre gives place to myxœdema. This second condition may be pellagra.

Whatever the true explanation may be, it is extremely probable that food deficiency, together with disordered function of certain endocrine organs, play a large part in the causation of epidemic dropsy and pellagra.

In conclusion, I must thank Lieutenant-Colonel P. S. Vickerman, late O.C. No. 2 Prisoners of War Hospital, Cairo, for his unfailing kindness and assistance in the making of these observations.

THE LATE MR. J. S. TURNER.—John Sidney Turner, J.P. for the County of Kent and for many years chairman of the Kennell Club, died on Jan. 16th at the age of 76. He received his medical education at Guy's Hospital, and qualified by taking the M.R.C.S. Eng. and the L.S.A. in 1864. After holding a house appointment at Guy's he subsequently became prosector of anatomy at the Royal College of Surgeons of England, afterwards becoming consulting surgeon to the Norwood Cottage Hospital. He was a Fellow of the Linnean Society, a member of Council of the Lister Institute of Preventive Medicine, and a Fellow of the Royal Society of Medicine. Mr. Turner, who was editor of the "Kennel Encyclopædia," was well-known in dog-breeding circles as judge, referee, and exhibitor

THE TREATMENT OF CHRONIC GONORRHŒAL RHEUMATISM BY VACCINES GIVEN INTRAVENOUSLY.

BY ARCHIE R. FRASER, M.D. ABERD.,
LATE OFFICER IN CHARGE VENEREAL DEPARTMENT, —— GENERAL HOSPITAL; LATE OFFICER IN CHARGE GONORRHŒA WARDS, —— WAR HOSPITAL;
AND
A. G. B. DUNCAN, M.D. ABERD.,
LATE OFFICER IN CHARGE GONORRHŒA WARDS, —— WAR HOSPITAL.

UP to the present the accepted view has been that a vaccine is of use in only one disease. In 1915 Sir Almroth Wright,[1] the greatest pioneer of specific therapy, said:—

> All of those who have had experience with vaccines will have seen cases where therapeutic effects, lying quite outside the range of the particular vaccine employed, and therefore, as we thought, not quite creditable to science, have been obtained with vaccine therapy.

In March of this year, going much further, he says[2]:—

> I confess to having shared the conviction that immunisation was always specific. ...... Presumptive evidence of collateral immunisation began gradually to filter into our minds. ...... Hints are conveyed to us that there may exist a useful sphere of application for collateral immunisation; and that such sphere may, perhaps, be found in those cases where the infection is of very long standing. ...... We should discard the confident dogmatic belief that immunisation must be strictly specific. ...... We should proceed on the principle instead that the best vaccine to employ will always be the vaccine which gives on trial the best immunising response against the microbe we propose to combat.

It is well known that when a patient suffers from two pyrexial diseases, such as measles and scarlet fever, at the same time, his symptoms are not a summation of the two unless we suppose each disease to be exhibiting only half its average degree of severity. Again, an existing disease may be modified by an intercurrent malady. For instance, on several occasions we noticed in the gonorrhœal patients in a military hospital that a relapse of malaria, with a hyperpyrexia and the parasites demonstrable in the blood, dried up the urethral discharge very quickly—much faster than ordinary treatment measures. Usually the discharge reappeared shortly after the subsidence of the fever, but Culver[3] has described a case of acute gonococcal urethritis which was cured spontaneously by a malarial relapse lasting four days.

During the influenza epidemic last winter some of our cases of chronic gonorrhœal arthritis became victims. These cases had been bedridden for months, and were showing no response to treatment, in spite of the fact that all the most hopeful lines had been tried on them. We noticed that during and for some time after the influenzal pyrexia there was a marked lessening of the arthritic pains in these patients, and some freedom of movement in the affected joints resulted. It is fairly well known in India that the more elderly natives submit to plague inoculation not from dread of plague nor faith in the vaccine, but because experience has taught them that it eases their rheumatism.

Artificial Rise of Temperature as a Means of Combating Infection.

Consideration of these facts led us to think that a rise of temperature must help the tissues considerably in counteracting germs and their toxins. Rolly and Meltzer,[4] Lüdke,[5] and numerous other workers found that a temperature of 104°–107° F., artificially produced, had a favourable influence on an established infection. Heated animals were more resistant to injections of bacteria, and agglutinins and bacteriolytic substances were produced more abundantly in animals which were kept overheated. The heat may damage the infecting organism or it may cause a more rapid and firm union of antigen and immune body.

Petersen and Jobling,[6] using experimental animals, injected intravenously such substances as bacteria, kaolin, protein-split products and trypsin, and found that, almost invariably, the injections were followed by an increase of serum, protease, and lipase. They found similar reactions in patients after intravenous injections of vaccines and of proteoses, though to a lesser degree and with less regularity than in animals. They observed improvement in cases of established infection following such injections, and suggested that the ferments might digest the microbes and their toxins. They also found that the injections caused a transient decrease of antiferments in the blood (perhaps due to the greater metabolic demands in pyrexia), followed by a distinct and much more lasting increase. Certain conditions of low "infection index," such as cancer, pregnancy, and after vaccine treatment, also show a relatively high "antiferment index."

In the following cases we gave the vaccines intravenously. A quick reaction marked by a rise in temperature was the result, but there was no marked change in the pulse-rate, nor was there any other untoward symptom. According to Wright, vaccine injections are followed by a negative phase, at least as far as the opsonic power is concerned. Bull,[7] on the other hand, found that intravenous injections of typhoid vaccine in immunised rabbits caused only rapid increase of antibodies. Dunklin,[8] working with Jobling, found the same increase after intravenous injections of proteoses.

We think that giving the injections intravenously secures a greater protection and that almost at once. The mechanism would seem to consist of a selective stimulation of the hæmopoietic system by non-specific bodies. Probably no single factor is responsible for all the changes that occur, but the intravenous injection upsets the balance of the serum constituents, and the series of changes thus caused establishes a condition favourable to recovery from infection.

The vaccines we used had been stored for some months after their preparation, and they were, therefore, probably more or less detoxicated.

Whether a detoxicated vaccine has any specific properties or not requires proof. We strongly suspect that a vaccine minus its endotoxin consists simply of non-specific proteose in a colloidal form. Clinically we seem to get the same results from injections of T.A.B. vaccine as from a gonococcus or mixed vaccine. Our chief reason for using a gonococcus vaccine was that a supply was available, and its use afforded a greater facility for graduating dosage. Freshly prepared typhoid vaccine often causes so severe a reaction when given subcutaneously that we would not risk giving it intravenously. Probably the best vaccines to use would be vaccines detoxicated as described by Thomson,[9] but these were not available at the time. Injections of endotoxins always produce toxic symptoms with but little or no increase of antibodies.[10]

Record of Cases.

The four cases recorded below are typical of a series of 15 which were treated in the same way.

CASE 1.—A. B., age 29, had a history of gonorrhœa at the age of 22. On admission he showed a slight urethral discharge, chiefly mucus. There were present numerous pus cells and scanty gonococci. Both knee-joints were very much inflamed, swollen, painful, and full of fluid. Both shoulder-joints were similarly affected and both hip-joints. His general condition was very poor indeed, he had been bedridden for six months, and he was very thin and emaciated. He could not move either arm or leg, and therefore could not get up to irrigate. The urethral condition was treated locally, both urine glasses showing considerable muco-pus. His prostate was massaged weekly. Table I. is an account of the treatment he received for his rheumatism, and the progress he made:—

TABLE I.

Day.	Vaccine.	Time ad-ministered and max. pulse.	Time and degrees of max. temp.	Temp. again normal.	Progress.
1	25 mill. GC.	10 A.M. 92	4 P.M. 100·4	6 A.M.	Nil.
4	35 mill. GC.	10 A.M. 94	4 P.M. 103	9 ,,	Both hip-joints less painful.
9	1 c.c. T.A.B.	10 A.M. 92	4.30 P.M. 102	9 ,,	Swelling right knee reduced.
13	100 mill. GC.	10.30 A.M. 96	5.10 P.M. 103·2	9 ,,	Slight movement right knee.
17	200 mill. GC. 2000 mill. Diph.	10 A.M. 100	4.30 P.M. 104·8	6 ,,	Marked improvement; some movement possible in both knees.
21	1½ c.c. T.A.B.	10.30 A.M. 86	4.30 P.M. 104	6 ,,	Movement possible in shoulders.
26	400 mill. GC. 4000 mill. Staph.	10 A.M. 84	4 P.M. 103·6	,,	Swelling subsiding.
31	2 c.c. T.A.B.	10 A.M. 86	7 P.M. 103·2	10 ,,	All joints improved.
35	600 mill. GC. 6000 mill. Diph.	9.30 A.M. 80	3 P.M. 102·6	6 ,,	Patient able to get up in invalid chair.
39	800 mill. GC. 8000 mill. Diph.	10 A.M. 80	5 P.M. 104·4	9 ,,	Can walk length of ward with cane.
43	2 c.c. T.A.B.	10 A.M. 80	8 P.M. 103·6	9 ,,	General condition very much improved; appetite returning.
47	1000 mill. GC. 10,000 mill. Staph.	Noon 76	8 P.M. 103·2	9 ,,	Showing steady improvement; gaining ground daily.
52	1200 mill. GC. 12,000 mill. Diph.	10 A.M. 78	4 P.M. 102·8	6 ,,	Can walk with comfort with a cane.
57	2 c.c. T.A.B.	Noon 72	4 P.M. 100	6 ,,	Can occasionally discard cane; other joints practically well.
60	1400 mill. GC. 14,000 mill. Staph.	10.30 A.M. 72	5 P.M. 103	6 ,,	Has walked one mile.

General condition is now excellent. Movements in all joints are good and the patient can walk twice round the grounds without a cane. He was recommended three weeks in the country and thence to duty.

CASE 2.—C. D., age 28, had had three attacks of gonorrhœa. On admission he had a purulent urethral discharge, gonococci present in large numbers, pus in both urine glasses, and a very marked synovitis of left ankle. After being three months in hospital, during which time his urethral condition got well and his arthritis got worse, he came under our care. Both ankles were now involved, there being marked swelling and tenderness and considerable fluid present. The left ankle was larger than the right. He was on fish diet; his appetite was poor and his general condition wretched. He was very depressed and had very little interest in his surroundings. His pulse-rate ran from 90 to 100. His subsequent treatment and progress is set out in Table II.

This patient eventually turned out for physical training under the hospital P.T. Sergeant-Major, could walk two miles without a cane, and was discharged to duty 72 days after his first intravenous injection.

TABLE II.

Day.	Vaccine.	Time ad-ministered and max. pulse.	Time and degrees of max. temp.	Temp. again normal.	Progress.
1	½ c.c. T.A.B.	10 A.M. 100	10 P.M. 106·2	Noon next day.	Can tolerate no movement whatever.
7	½ c.c. T.A.B.	10.30 A.M. 104	11.30 P.M. 104·4	Noon next day.	No change.
11	1 c.c. T.A.B.	10 A.M. 102	10 P.M. 103·8	9 A.M.	Can tolerate slight movement.
16	100 mill. GC. 1000 mill. Diph.	10 A.M. 100	11.30 P.M. 105·6	Noon next day.	Swelling left ankle reduced.
20	1½ c.c. T.A.B.	11.30 A.M. 92	1 A.M. 103·8	9 A.M.	Pain left ankle subsiding.
25	200 mill. GC. 2000 mill. Diph.	10 A.M. 86	10.30 P.M. 104·6	9 ,,	Both ankles much improved.
30	400 mill. GC. 4000 mill. Staph.	10 A.M. 80	11.30 P.M. 104·6	6 ,,	Some movement now possible.
34	2 c.c. T.A.B.	9.30 A.M. 78	10 P.M. 103·8	6 ,,	Movements freer.

CASE 3.—E. F., age 26, had had two attacks of gonorrhœa, the first at the age of 20. His urethral condition had cleared up. He had been confined to bed for three months when he came under our care. At that time he was in a wretched condition, worn to a shadow, tongue heavily coated, marked anorexia, and badly constipated. His arthritis included the right shoulder, right wrist and thumb, left wrist, both knees, and both great toes. Each joint showed considerable swelling, redness, pain, and tenderness. Fifty-two days after his initial intravenous vaccine he was discharged from hospital. He was then comparatively well-nourished, had good movements in all joints, and had done over one week of physical training under the hospital P.T. Sergeant-Major. His vaccine treatment was as shown in Table III.

CASE 4.—G. H., age 27, had had three attacks of gonorrhœa. He had been bedridden for five months, and had received gonococcal vaccines (stock) subcutaneously during that period with little or no improvement. He was very much emaciated, in spite of extras in his diet, cod-liver oil, cream, daily massage, and so on. He could not sit up in bed, and he had to be spoon-fed by an R.A.M.C. orderly. There was marked wasting of the muscles of the thighs and calves, and of the left forearm. The joints involved were the metacarpophalangeal joints of the right hand, the left elbow, both knees, and the right ankle. Progress at first was very slow and often disheartening, but eventually he began to pick up, the joints improved in a wonderful manner, and once out in an invalid chair he made very rapid progress. During the whole of his vaccine treatment his bed was moved out on the balcony and remained there day and night. Every effort was made to induce him to eat and take a general interest in things. The muscles of both legs and left arm were massaged daily. His vaccine treatment and progress are detailed in Table IV.

TABLE IV.

Day.	Vaccine.	Time administered and max. pulse.	Time and degrees of max. temp.	Temp. again normal.	Progress.

87	1800 mill. GC. 18,000 mill. Staph.	9.30 A.M. 72	6.30 P.M. 104	6 ,,	Grip of right hand quite good. Free movements left elbow.
92	2000 mill. GC. 20,000 mill. Staph.	Noon 76	6 P.M. 104·8	6 ,,	Now walking about grounds with one cane. General condition is extremely good. All joints are practically normal.

Conclusion.

The following we consider the most noteworthy points:—

1. The marked improvement in all cases.
2. That no benefit seemed to result from an injection that was not followed by pyrexia.
3. Though the temperature rose there was no change of any importance in the pulse-rate nor any other untoward symptom. At the time treatment was commenced the patients were extremely debilitated with a rather fast and weak pulse, which was easily accelerated.
4. The injections were all intravenous.
5. There was no appearance of a clinical negative phase.
6. The vaccines we used were not freshly prepared. As a result of storing, probably the toxins contained had broken down more or less.
7. The injection of these, possibly, non-specific germ constituents would seem to have caused the production of specific antibodies.
8. The size of the doses used. These compare favourably with the doses recommended by Thomson for his detoxicated vaccines. The doses of pus vaccines used by Pineo and Baillie[11] seldom exceed 72 million given subcutaneously and never exceed 150 million. The largest dose of gonococci used by us was 2000 million.

We are indebted to Lieutenant-Colonel Wm. Robertson and Lieutenant-Colonel E. B. Booth, D.S.O., for facilities in compiling and using records of this series.

THE LATE MR. ERNEST SAXTON.—Ernest Saxton, L.R.C.P. & S. Edin., L.R.F.P.S. Glasg. died suddenly on the evening of Jan. 13th at his home at Didsbury. It was known that he was not in good health, but such a sudden end was not anticipated, and he was at work in his surgery when a fatal heart seizure occurred. An Edinburgh student, qualified in 1901, at one time he practised at Trentham, Stafford, having a district union appointment and public vaccinatorship in the Stoke union, and acting as honorary physician to the Hanchurch Convalescent Home for Children. He came to Manchester some ten years ago to take up the practice of the late Dr. J. M. Rhodes, and has since worked in the Didsbury district, except for the time he was abroad on war service in the East. He leaves a widow and one son, with whom great sympathy is felt in their sudden loss.

A NEW PYLORUS.

POSTERIOR GASTRO-JEJUNOSTOMY WITH JEJUNO-JEJUNOSTOMY AS A ROUTINE OPERATION IN ALL CASES OF PYLORIC OBSTRUCTION—DUODENAL OR PYLORIC OR CHRONIC GASTRIC ULCER.

BY G. GORE GILLON, F.R.C.S. EDIN.,

CONSULTING SURGEON, AUCKLAND HOSPITAL; LATE LIEUTENANT-COLONEL ATTACHED R.A.M.C., AND SURGEON, LONDON MILITARY HOSPITAL.

I WROTE a paper on this subject in 1913, describing a series of operations for duodenal ulcer and read it before the Australasian Medical Congress held at Auckland early in 1914. Since then, in 1915, I published a short paper on the subject in the *British Medical Journal*, with a diagram.

History of the Operation.

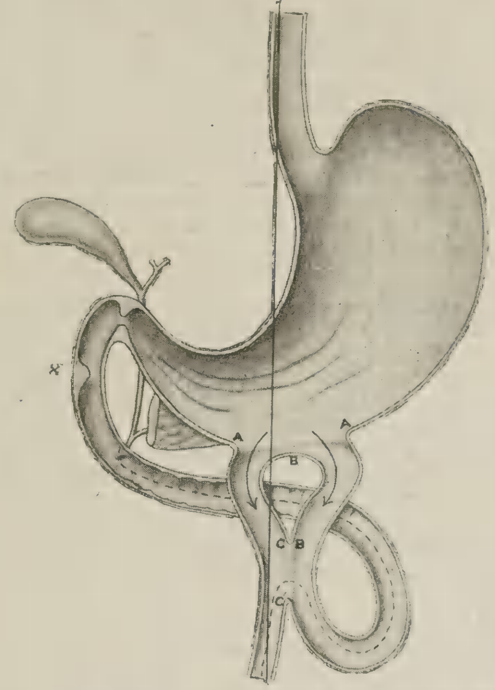
The history of this operation may be stated briefly. Braun, Weir, and Jaboulay performed a jejuno-jejunostomy over 20 years ago, but *only* when combined with an *anterior* gastro-jejunostomy.[1] Jaboulay published his paper in 1894 and Weir in 1898.[2] Jejuno-jejunostomy was done occasionally, as Sir Berkeley Moynihan has informed me, after these dates in England—as an addition to the posterior operation when a very long loop had been left. But this method quite went out of fashion as there were alleged against its use: (1) the occasional occurrence of a jejunal ulcer afterwards, and (2) the length of time involved in its performance. The "long loop" operation in the early days probably failed either because the loop was *too long* and so got kinked, or because the technique at that time was faulty and a certain number of cases of jejunal ulcer were reported as having followed as a sequel. The time for the double operation should never exceed 1 hour 20 minutes nowadays, allowing a few minutes for change of gloves for the second anastomosis. Thus this long loop operation was practically discarded 15 years ago, and surgeons all over the world have done the present operation of "no loop" posterior gastro-jejunostomy. This operation was and is undoubtedly a "cure" for cases of pyloric obstruction and duodenal and pyloric ulcer, and certainly the ulcer does heal and the obstruction is overcome. But there was much dissatisfaction as regards the results of the operation as time went on, many patients complaining of various uncomfortable sensations in the abdomen, and very many of them being in feeble health and unable to take hard exercise.

A New Pylorus.

When one sets about altering the mechanism of the alimentary tract—altering nature's plan—it surely behoves him to do so in a manner that shall produce no secondary disability. We must remember that the patient has presumably a long time to live with the modifications which the surgeon has effected. When we want to do away with the use of the old pyloric gateway we must make certain that the new gateway is situated at the *lower* end of the stomach (see figure), and by a jejuno-jejunostomy, some $3\frac{1}{2}$ in. away from the new pylorus, we can make sure that the food stream does not mingle with the bile and pancreatic fluids till the bowel is reached. By a jejuno-jejunostomy the duodenum gets a perpetual rest and the descending jejunal double tube takes the functional place of the first segment of the duodenum.

The accompanying figure shows Mr. Gillon's modified operation for short-circuiting the gastric contents.

I hold that the present-day "no loop" operation is physiologically incomplete; the bile and pancreatic fluids find their way into the stomach, and the long series of complaints noted by physicians are entirely and wholly due to this unnatural result of the conventional operation. These $3\frac{1}{2}$ in. of jejunum shown in the figure functioning as the first $3\frac{1}{2}$ in. of duodenum make all the difference in the world to the unfortunate sufferer. Digestion goes on naturally; he is never troubled with hyperacidity, and jejunal ulcers simply do not occur.



Diagrammatic representation of author's operation of posterior gastro-jejunostomy with jejuno-jejunostomy. Distance A to C = $3\frac{1}{2}$ in.; A to A = 3 in.; B to B = $2\frac{1}{2}$ in.; C to C′ = $1\frac{1}{2}$ in. X = ulcer. The dotted line shows the course of the bile and pancreatic fluid.

The Operation Described.

To prevent misconception I shall describe shortly my operation. After opening the abdomen and exposing the part of the stomach I require I put in my right hand and bring up from the left of the spine 10 in. of jejunum, counting from the duodeno-jejunal junction, immediately at the left of the second lumbar vertebra; 3 in. of this proximal loop are used to make the first anastomosis, leaving 7 in. for the second anastomosis. The gastro-jejunostomy opening is made 3 in. in length (see A to A in figure). My assistant and I now change our gloves and then make the anastomosis between the two descending legs of the jejunum at a distance of $3\frac{1}{2}$ in. below the stomach opening (B to B in figure). The anastomotic opening itself should measure $1\frac{1}{2}$ in. vertically (C to C′). The gastrocolic omentum is attached to the jejunum near the stomach by two stitches, and any veins in the omentum tied. I use fine silk or linen thread. The abdomen is then sewn up in the usual way. The vertical black line in the figure shows the position of the spine. A to A indicates the new pylorus, the arrows point out the direction of the food stream. The dotted line along the duodenum from Vater's ampulla to the jejunal opening, C to C′, shows the course of the secretions from the pancreas and liver to join the food stream issuing from the stomach.

---

[1] Vide Archiv f. Klinische Chir., 1823, xlv., pp. 3614 (Braun).

[2] Med. Record, 1898, vol. liii., p. 541.

The patient can lie in a recumbent position a few hours after the operation, and need not be propped up, hence there is less strain on the abdominal stitches. He is fed with tablespoonfuls of water for a day, and then peptonised milk in the usual way for a few days, and in eight days is taking a fair amount of light food. On the twelfth day he gets 2 or 3 gr. calomel; prior to that his bowels are opened by rectal injections if required. He should lie on his back for the first three weeks, and leave hospital on the twenty-fourth or twenty-eighth day. The operation has never taken me longer than 1 hour 15 minutes in an uncomplicated case. I have never had a case of jejunal ulcer afterwards.

Results.

The results are uniformly good, and the patients are not only well, but very well. They put on weight. They develop a great capacity for swallowing large quantities of liquids without discomfort. I may mention that three of my cases—two men and one woman—undertook a journey of some 1200 miles by sea within a few months after the operation, and although all three had previously been great sufferers from sea-sickness, yet they reported to me afterwards that they were not seasick and enjoyed their meals heartily all through the voyage, although it was winter time and the sea was very rough.

Notes of a case done a year ago.—Mr. ——, aged 30, height 5 ft. 10½ in., was operated on by me at St. Thomas's Nursing Home on Dec. 1st. 1918. He was admitted to the hospital on Nov. 16th, 1918, suffering from profound anæmia due to loss of blood for the past 12 years from a duodenal ulcer. He was so pale and bloodless that he had to be kept 15 days on special diet and have intravenous saline injections before he was fit for operation. His weight then was 8½ st. The operation, in which Mr. O. H. Hyman assisted me, took exactly 1 hour and 15 minutes. Three weeks after the operation the patient left the hospital, and in six months' time he had put on over 1½ st. in weight. He went back to work in April, 1919, and has been at work ever since, and has not the slightest sign of indigestion or any pain or inconvenience of any kind; his cheeks are a healthy red colour.

With regard to my experience of this operation I may say that during the last nine years I have carried it out in the way I have described in every case—as a routine practice. So convinced am I of its excellence that I adopt it in cases of perforation, either at the same sitting, or, where the patient was too weak, by opening the abdomen again in four weeks' time, and leaving meanwhile a good 7-in. loop of proximal jejunum for me to find when I make the second anastomosis.

Wimpole-street, W.

THE LATE DR. E. L. DUNN.—Edwin Lindsay Dunn, medical superintendent of the Berkshire County Asylum, who died at Wallingford on Jan. 12th, was an exhibitioner of Trinity College, Dublin, graduating in 1887 as B.A., M.B., B.Ch. He had held resident posts at the Liverpool Dispensary and the Liverpool Infirmary for Children before becoming assistant medical officer at the Wakefield Asylum, from which he went on to Wallingford.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

◆

A CASE OF

MEDIASTINAL TUMOUR ASSOCIATED WITH ACUTE LEUKÆMIA.

BY C. RHODES HARRISON, M.B., B.S. LOND.,
CAPTAIN, R.A.M.C. (T.F.);
AND
D. MCKELVEY, *M.C.*, M.R.C.S.,
CAPTAIN, R.A.M.C.
(From the Pathological Department, 3rd London General Hospital.)

THE association of mediastinal tumours of malignant appearance with the presence in the blood of enormous numbers of large mononuclear cells is of sufficient rarity to warrant the following brief note.

Corporal ——, aged 29 years, served continuously from August, 1914, and was quite healthy until April, 1919. He went sick to a C.C.S. in Belgium on May 31st, 1919, with history of pain and discomfort in the epigastrium shortly after food and occasional vomiting, which had been going on for about six weeks. Temperature was normal during the day, but rose to 99° F. in the evening. On June 20th he developed sudden swelling of the left arm due to thrombosis. On the 27th he came under our notice. He then complained of pain in the epigastrium, which became worse at night, but did not seem to have any definite relation to food. Examination of the abdomen revealed nothing except slight tenderness below the ensiform cartilage. As to the respiratory system, there were no subjective symptoms, but percussion revealed an area of intense dullness in the middle line, from the clavicle to the heart, and liver dullness, extending 2 inches to the right and 1 inch to the left of the sternum. No dullness could be made out posteriorly. X ray examination showed an opaque mass, which did not pulsate and did not move with respiration, behind the sternum, conforming with this area. The spleen and lymphatic glands were not enlarged.

A blood count showed: Red cells, 5,600,000 per c.mm.; total leucocytes, 86,000 per c.mm. The films showed among the leucocytes an enormous preponderance of cells, 10 to 15μ, having a single large pale-staining nucleus, round, oval, or indented. The oxidase reaction was not tried, but they appeared to be non-granular myelocytes. The differential count showed: Polymorph. neutrophils, 3 per cent.; polymorph. eosinophils, 0·5 per cent.; large mononuclear cells, 96·0 per cent.; neutrophil myelocytes, 0·5 per cent. Small lymphocytes were scanty, and a few normoblasts were seen. The patient sank gradually, dyspnœa and cyanosis appeared, and he died on July 22nd. On the day before his death a blood count showed: Red cells, 4,100,000 per c.mm.; total leucocytes, 210,000 per c.mm.

Post-mortem Findings.

At autopsy a large mass, white and very tough, about the size of a cocoanut, was found in the mediastinum, spreading down over the heart and enveloping the borders of the lungs in such fashion as to resemble on section greatly thickened pleuræ. Behind and laterally the mass had infiltrated the lungs and bronchial glands, the latter being in places recognisable by the unaided eye only by the arrangement of black pigment. There were no metastases. Microscopically, the tumour mass showed (Fig. 1) cells resembling the leukæmic cells of the blood supported by a stroma which was in places dense and hyaline. The edges showed a looser and more cellular texture of leukæmic cells with a free capillary supply. Wherever examined the growth passed by infiltration into the adjacent tissue, as is seen in Fig. 2, the section being made where the visceral pericardium is replaced by a sheet of growth ½ to ¾ of an inch thick, the free surface of which is lined by a layer of flattened cells, while the cells of the other passed freely between the muscle fibres of the heart wall. A similar condition is present where the sheet of tissue invades the lungs and pleuræ. No evidence was found of thymic tissue. The spleen was but little enlarged, showing (microscopically) leukæmic infiltration; the Malpighian bodies and their germ centres were very clearly marked. The liver showed some infiltration, while the kidneys were almost unaffected. The abdominal glands were only very slightly enlarged, as were the axillary, cervical, and inguinal; microscopically, there was leukæmic infiltration, but the general structure of the glands was unaltered. The bone marrow of the sternum showed masses of the leukæmic cells, together with megacaryocytes, myelocytes, and erythroblasts.

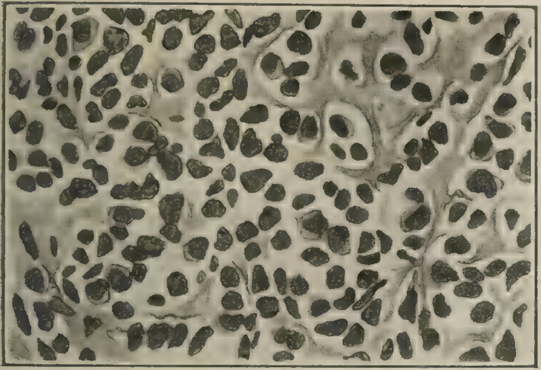

FIG. 1.—Section of mediastinal tumour.

Remarks.

This association of mediastinal tumour and escape of cells into the blood stream is of considerable rarity and of great interest on account of the possible connexion between the leukæmias, lymphadenomata, and lymphosarcomata. Sternberg held that there were two distinct conditions: (1) Increase of cells of the small lymphocyte type with hypertrophy of the lymphatic apparatus and infiltration of the various organs—that is, lymphatic leukæmia; and (2) mediastinal leukosarcomatosis as described above. Fraenkel, on the other hand, thought that (2) was simply a leukæmia tending to form tumour-like masses of cells having the appearance of malignant growths. The situation of the growth suggests association with the thymus, and appearances have been described in similar cases which resemble Hassal's corpuscles. In this connexion it may be mentioned that Gamgee has described a lymphosarcoma of the thymus with no increase of white cells in the blood, while Lochte mentions two cases of enlarged thymus "epithelioid transformation" associated with acute lymphatic leukæmia.

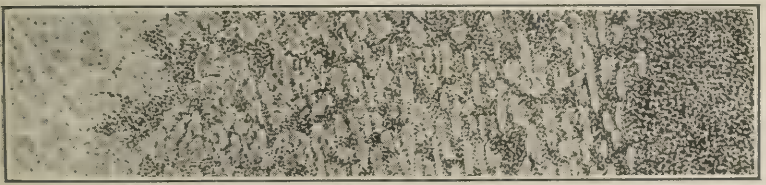

FIG. 2.—Section showing infiltration of heart wall.

The case described above presents one very remarkable feature, the high proportion of red cells right up to the time of death. For comparison, counts of other cases are given:—

(1)	Red cells:	1,500,000 per c.mm.;	leucs.:	176,000.	(Parkes Weber.
(2)	,, ,, :	1,600,000 ,, ,,	,, :	103,125.	(,, ,,)
(3)	,, ,, :	1,472,000 ,, ,,	,, :	295,000.	(O'Kelly.)
(4)	,, ,, :	2,000,000 ,, ,,	,, :	60,000.	(St. Bart.'s Mus.)
(5)		——	,, :	810,000.	(Mager.)
(6)	,, ,, :	4,100,000 ,, ,,	,, :	210,000	—case described here.

In conclusion we wish to express our thanks to Majors W. Essex Wynter and A. F. Voelcker, R.A.M.C. (T.F.), for their kind assistance.

A NOTE ON THE

"NEW GAS AND ETHER."

BY J. BLOMFIELD, O.B.E., M.D.CANTAB.,
SENIOR ANÆSTHETIST AND LECTURER ON ANÆSTHETICS, ST. GEORGE'S HOSPITAL.

BY "gas and ether" is usually meant, since the day of Clover, its inventor, a method of anæsthesia in which nitrous oxide plays a merely preliminary part in the induction, the maintenance of anæsthesia being entirely supported by ether. By "new gas and ether" I mean a method in which nitrous oxide is relied on throughout, and ether plays the supplementary part. The one is continuous ether with preliminary gas, the other continuous gas with occasional ether. It is a system which is widely applicable, gives good results, and requires only comparatively simple apparatus, for which reasons I venture to draw attention to it, although, no doubt, other anæsthetists have, like myself, been in the habit of using "gas and ether" apparatus in this way for years. I do not, however, remember having seen it definitely described.

The apparatus necessary is merely a Clover's inhaler, preferably the wide-bore modification, and attached to it an ordinary 2 gallon bag with Hewitt's stopcock, connected with gas cylinders. With a small prop between the teeth, and the head turned well to one side, the face-piece is accurately fitted to the face while the bag is about two-thirds distended. The induction is now carried out as ordinarily with "gas and ether." That is to say, unconsciousness is secured with gas only, an ounce and a half of ether then put into the chamber, the expiratory valve shut, and the indicator fairly rapidly advanced till at the end of about four minutes there is stertor and full narcosis.

From now onwards, instead of getting rid of the "gas," as in the old method, the aim is to use it all the time and the ether as little as possible. The procedure is as follows:—

If the patient is a muscular man or in any way what is called a difficult subject let the indicator be advanced quite to "full" in the course of the induction. When anæsthesia is present turn the indicator rapidly back to "0." The patient is now re-breathing a mixture of N_2O, E., and expired air with CO_2. Open the expiratory valve, thus emptying the bag, and at once fill it two-thirds full again with N_2O, which you allow to be re-breathed. Give breaths of air by means of the stopcock as often as it is necessary to do so to keep the colour free from all blueness. Empty the bag, by opening the exploratory valve, about every five minutes. Any indication that the narcosis is too light is met by advancing the indicator and admitting a little ether.

By this simple method a great many patients can be kept satisfactorily anæsthetised by an inhalation which is for the most part one of nitrous oxide. Consequently they are saved from the after-effects, which are the drawback to ether. At the same time they have the pleasant and quick induction

due to nitrous oxide and they are provided with such advantages as may accrue from small quantities of CO_2 and from a vapour which is warmed. The completeness of relaxation which can be achieved depends a good deal upon the extent to which ether is admitted. For abdominal operations this is not a good method unless an oxygen cylinder is connected up with the bag, in which case results can be obtained equal, I think, to those that are secured by the fashionable "sight-feed" machines. In the absence of oxygen I find that too much ether is needed to get abdominal relaxation for this method to be any superior to open ether or to a C.E. mixture. Relaxation, in fact, is largely a matter of oxygenation. It is for such operations, though, as were so frequent in war surgery—long operations upon bones and sinuses of the trunk or limbs—that I have found the method so very useful, both because of the condition obtained on the table and for the freedom from much sickness afterwards. Here, for example, is a case typical of what I wish to enforce:—

Oct. 24th, 1917: Captain ——, in good health, slight build. Operation: reamputation of thigh; anæsthesia by "new G. and E.," 1 ounce of ether in wide-bore Clover; indicator to "F." during induction, then "E." off altogether and "G." re-breathed. Frequent breaths of air needed to keep colour good. Twice "E." admitted for a minute at a time on account of slight movement in other leg. Slight cyanosis allowed several times. No signs of shock. At end of 40 minutes operation finished. Patient talking within five minutes and very incredulous of operation having been performed. No after-sickness, no discomfort.

Another patient who had undergone a plating of the femur under C.E. narcosis had suffered greatly from sickness, so at a second operation I used this "new gas and ether." The operation took 50 minutes and he was conscious within three minutes, not nauseated at all, and feeling "quite happy." This patient was pale from long sepsis and needed very free aeration.

With this method, as with all others, perfect results are not to be obtained with every kind of subject. Very fat persons, and those with narrow or obstructed upper air-passages are unfavourable. By modifying the procedure through the introduction of oxygen, in the feebler kind of subject, and small quantities of chloroform added to the ether in the robust kinds, the great majority of patients can, however, be very well managed for a great variety of operations. When chloroform is added it should not be in proportions greater than 1 to 12 of ether. Generally speaking, it is not the method of choice for operations upon the upper abdomen, and is, of course, out of court where the face is concerned, except for very short procedures. It provides an excellent anæsthesia for rectal operations, for curetting the uterus, and for such proceedings as radical cure of hernia and hydrocele, and all operations upon the limbs.

LITERARY INTELLIGENCE.—Messrs. William Hodge and Co., Ltd., London and Edinburgh, announce for early publication, in their series of Notable Trials, "The Trial of Hawley Harvey Crippen."

ENHAM VILLAGE CENTRE.—The town of Southampton has collected towards the funds of the Enham Village Centre the sum of £500, which will be devoted to the erection and equipment of a basket-making shop, called the "Southampton Hut." It is hoped that many other towns in the United Kingdom will follow the lead given by Southampton. Subscriptions should be sent to the Secretary, The Village Centres Council for the Curative Treatment and Training of Disabled Ex-Service Men, 51, Lincoln's Inn-fields, Holborn, W.C. 2.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OTOLOGY.

EXHIBITION OF CASES AND SPECIMENS.

A MEETING of this section of the Royal Society of Medicine was held on Jan. 16th, Mr. HERBERT TILLEY, the President, being in the chair.

New Knowledge on the Vestibular Structure.

Dr. ALBERT A. GRAY (Glasgow) demonstrated, by means of a series of beautiful slides, some previously unrecorded anatomical details of the human vestibule, relating at the same time how the discovery was made. The first is a curious band of cartilage which encircles the oval window. The foot-plate of the stapes has a layer of cartilage on its vestibular surface, but no observer has pointed out that there is a considerable layer of cartilage extending over the inside of the vestibular wall, towards the cochlea, above the vestibule, and posteriorly towards the semi-circular canal. Another feature which he regards as new is a cleft coming down from the anterior margin of the oval window. This he has found to vary a good deal in different cases. Posteriorly, in many cases, Dr. Gray found a foramen of 1/10 mm. behind the posterior margin of the oval window. Another feature, which the demonstrator found it difficult to explain, concerns the position taken up by the stapes after death. In the exhibited specimens the stapes is rotated on a vertical axis, which passes through the junction of the middle and posterior thirds. Stereograms show that the stapes in the cadaveric position is not in the same plane as the wall of the oval window round about it, but the anterior two-thirds of it is rotated inwards, and the posterior third outwards. That he attributed to the action of the stapedius muscle, possibly, in his opinion, it is due to the spasmodic contraction of that muscle in the death agony, or to rigor mortis. In the ninth specimen which he examined the crura and the stapes had been rotated by caries or by cholesteatoma, and there was no drag on the stapedius muscle; and in that instance the foot-plate of the stapes was in the same plane as the oval window. This seems to give a clue to the function of the stapedius muscle. The cartilaginous layer Dr. Gray regards as a remnant of the cartilage surrounding the otocyst in lower forms of animal. Some authorities, he said, considered this change of bone in front of the oval window to be the cause of otosclerosis, but he thought these cells played more than a passive part in otosclerosis. The bony change seemed to always begin in the cochlear portion, never behind the oval window, though extension to the latter might occur. The persons from whom the specimens were removed were between the ages of 20 and 65.

The PRESIDENT cordially congratulated Dr. Gray on his work.

Cases of Meningitis and Labyrinthitis.

Mr. J. S. FRASER and Dr. J. K. MILNE DICKIE (Edinburgh) described an interesting series of cases—i.e., three examples of epidemic cerebro-spinal meningitis, and one of pleuro-pneumonia, bronchiectasis, meningitis, and labyrinthitis. In connexion with meningitic labyrinthitis the authors said that though most of the cases of labyrinthitis resulted from middle-ear suppuration, a minority were due to purulent lepto-meningitis, and in these latter, labyrinthitis secondary to epidemic cerebro-spinal meningitis occupied the first place. They agreed with those who considered that mumps deafness was secondary to meningitis. The original site of infection must be the upper or lower respiratory tract, the parotid gland, the tonsil, the alimentary tract, or other parts, but in all cases probably invasion of the blood stream was the next step in the production of meningitis. Mr. Fraser suggested that cases of meningitic labyrinthitis were much commoner than is generally supposed. He regarded them as a very common cause of deaf-mutism. A child at an age prior to that at which talking was learned had meningitis, possibly connected with pneumonia or some zymotic disease. Infiltration occurred along the eighth nerve, passed to the cochlea, destroyed the inner ear, and the child never talked. It was probably considered to be a case of congenital deafness, whereas it was really acquired deafness, due to early labyrinth suppuration.

Dr. GRAY said he thought Mr. Fraser's suggestion concerning the cause of deaf-mutism after any form of meningitis was probably correct, because after epidemic cerebro-spinal meningitis deafness was very much more common than blindness. If that were due to the effect of the change within the cranium, why should that be so?

Dr. DAN MCKENZIE asked whether meningitis was ever induced by middle-ear suppuration extending along the facial canal and meninges only. Was it not true that the cases formerly reported as due to infiltration along the facial canal were also cases in which there was labyrinth suppuration from without? In most of the old records either the labyrinth was not mentioned, or the statement was made that pus existed in the labyrinth, hence in those instances it was impossible to say whether the meningitis was induced by irritation along the facial canal alone.

Dr. P. WATSON-WILLIAMS (Bristol) raised the question of the recoverability of children who were affected with suppuration involving the labyrinth. He discouraged the tendency to regard these cases as hopeless from the point of view of saving life, with the consequent failure to pursue active measures. He related such a case in his own practice in which he did a labyrinthectomy, opened the external semicircular canal and the cochlea, did repeated lumbar puncture, and used intravenous and intrathecal injections of colloidal silver, with the happiest result.

Mr. W. STUART-LOW congratulated Mr. Fraser and Dr. Dickie on their work, and said he had been struck with the number of these cases which were seen in large clinics. At his hospital the practice was to take such patients into the hospital so as to treat them adequately. In some instances he had done a cortical mastoid operation and it had produced benefit by draining the ear and setting up a better circulation. Help was also given by small frequent doses of mercury. He considered that the channels of infection were the throat, Eustachian tube, and middle ear. He believed that fugitive evanescent otitis media sometimes occurred without symptoms, and at such times infection of the labyrinth was set up.

Mr. SYDNEY SCOTT said he was interested in the question whether infection always took place from the labyrinth to the meninges or more frequently from the meninges, pia arachnoid, and seventh and eighth nerves to the labyrinth. He was not inclined to accept, without further evidence, Mr. Fraser's view that infection necessarily spread from the meninges to the labyrinth and then to the middle ear, because there might occur acute otitis media with infection in the naso-pharynx, which might resolve in the pharynx while it was still persisting in the tympanum; also that in certain parts of the tympanum the infection resolved while it persisted in some of the niches of the tympanic cavity. And the condition of the round window was such that in some cases there might be an unresolved infection in that region, though the infection had disappeared everywhere else.

Mr. FRASER replied.

Sarcoma of Middle Ear Arising in Eustachian Tube.

Mr. RICHARD LAKE showed a man, aged 33, who, while in Canada in 1918, complained of deafness in the left ear, and towards the end of the year pain in that ear and the left side of the head. In the following May a Vancouver aurist removed an aural polypus, a post-nasal growth, and the tonsils. Recurrence of the two latter took place in six weeks. A further operation was done in November, 1919, which Mr. Lake described. The healing of the cutaneous wound was immediate. A radium tube was buried in the middle ear for 12 hours. The health was now improving. The pathologist's report showed the growth to be a spindle-celled sarcoma involving the middle ear.

Transplantation of Masseter Muscle for Facial Paralysis.

Mr. SOMERVILLE HASTINGS showed a woman, aged 35, on whom labyrinthectomy had been carried out for severe giddiness of three years' duration, with the result that the giddiness was cured, but she had facial paralysis, with some necrosis of bone and some discharge from the ear. The result of the transplantation was a reduction in the deformity and the restoration of some movement at the angle of the mouth.

Mr. E. D. DAVIS showed an interesting series of cases. In the first the patient, who had resided in India many years, had suffered for 10 years from otitis externa and dermatitis. There was also much stenosis at the junction of bony and cartilaginous meatus. A conservative mastoid operation was done; no skin-grafting. The result was satisfactory, but there had been one attack of dermatitis since. The hearing was now improved. In the next case, a youth, aged 20, had stenosis of the meatus following the removal of a large sessile exostosis which extended from the meatal orifice to the drum. Stenosis recurred very soon after the removal of the drainage-tube, and had continued in spite of the insertion of a tightly-fitting smaller tube.

Mr. Davis next showed post-mortem specimens from a case of cerebellar abscess which was complicated by thrombosis of the lateral and the cavernous sinuses. There were two operations, and the patient died 24 days after the second. There was no meningitis. He also exhibited a sequestrum of the cochlea and semicircular canals following a fatal case of extensive encephalitis of the temporo-sphenoidal lobe.

Mr. ARTHUR CHEATLE exhibited a specimen of Aspergillus which was obtained from a mastoid cavity.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

EXHIBITION OF CLINICAL CASES.

A MEETING of this section of the Royal Society of Medicine was held on Jan. 23rd, Mr. J. P. LOCKHART-MUMMERY, the President, being in the chair.

Œsophagectasis in an Infant.

Dr. FREDERICK LANGMEAD contributed the notes of a case of Œsophagectasis in an Infant, with radiograms.

The patient, a girl infant, was born at full term by a normal labour. She was a very small baby, weighing no more than 4 lb. at birth. Shortly after birth it was noticed that "something was wrong with her stomach." On the first day she retched and "vomited," even before her first feed. She was breast fed for one week, during which time she "vomited" occasionally, and her stools were green. At one week she was weaned and put on cow's milk and water. She was now constipated, but the "vomiting" continued; it occurred about an hour after food, was not projectile, and was often brought on by change in posture. At four months she was wasted and weighed "no more than 3 or 4 lb." Afterwards the "vomiting" was not so frequent and occasional feeds were retained. The constipation continued, hard small stools being passed. After her feeds she used to be very quiet, pale, and "collapsed," but recovered, and the colour returned after "vomiting." She slowly gained weight and reached 14 lb. 5 oz. at a year and three months old, one month before admission. For three or four months before admission the "vomiting" followed immediately after or coincided with a meal, and the food "did not seem to enter the stomach at times." The vomit was unaltered milk, sometimes accompanied by mucus. The father and mother were both healthy, and there was no history of neurasthenia or neuroses on either side of the family. The patient was the third child in a family of three, the elder members being quite well. No miscarriages.

On admission to hospital on Nov. 28th, 1919, the child was found to be fairly well developed and nourished, but with a pale face, slightly sunken eyes, and hanging folds of skin, indicating recent loss of fat. The fontanelle was slightly depressed. There were no signs of rickets. Examination of the abdomen revealed no tumour or gastric peristalsis. Heart and lungs were apparently normal. The knee-jerks were very exalted, otherwise there were no abnormal nervous phenomena. The urine contained acetone in definite amounts. After admission the child cried incessantly, apparently without pain. A stomach-tube was passed, but no food washed out. During the first 24 hours the child refused all food and was fed by a tube; she "vomited" afterwards. Next day she took equal parts of milk and water a little better, but cried almost continuously if not nursed or petted. A single vomit contained mucus; the milk was not digested and contained no curd. On Dec. 4th, six days after admission, X ray examination was made after a bismuth meal. Three screenings were done, one immediately after the meal, one an hour later, and the last three hours later. A dilatation of the œsophagus was detected near its lower end, centrally placed, and about the size of a hen's egg. Immediately after the meal most of it was seen to be retained in the œsophageal sac, but some had passed on into the stomach. The second and third screenings showed that part of the meal was still retained. There was no obstruction in the alimentary tract below the cardia.

As the result of this examination an attempt was made to pass a stomach-tube twice a day with a view to introducing food and dilating the cardia. This appeared to be successful, but there was some doubt whether the tube curled up in the sac or traversed the cardiac opening; the vomiting was now less, but only 6 oz. could be held, the rest flowing back. To elucidate this point an opaque tube was passed under X rays, and it was found that the tube, ⅓ in. in diameter, would not pass through the cardia, but curled back into the sac on reaching the lower end. Since the child was losing weight and a tube could not be passed, Mr. O. Addison was good enough to see her with a view to surgical treatment. The œsophagus was examined with an œsophagoscope, which passed freely into the stomach under an anæsthetic, and revealed no organic cause for the retention of food in the gullet. No operation was considered advisable.

The case appeared to be one of œsophagectasis due to want of relaxation of the cardiac sphincter dating from birth, and to be similar to the examples of greatly dilated œsophagus recorded in adults. The absence of cough and dyspnœa, such as occurs in adults, could be explained by the relatively small degree of dilatation. There was probably a close analogy between this condition and that of pyloric spasm, and it would appear that it bears the same relationship to hypertrophic stenosis of the cardia that pyloric spasm does to hypertrophic stenosis of the pylorus. An example of hypertrophic stenosis of the cardia was shown before the last meeting of this section by Dr. Eric Pritchard; this was associated with hypertrophic stenosis of the pylorus. In this case the disorder at the cardia was the only defect. The endoscopic examination was important as demonstrating the absence of an organic lesion.

Dr. F. PARKES WEBER said that the condition had been found at all ages, and related the case of a man of 70 in whom no cause for the obstruction was found after death. Fatal cases occurred in adults, the patients dying of starvation. Early infancy was one of the recognised times for the disorder to make its appearance, and he quoted examples from the literature in which the diagnosis had been made in infancy, including a few instances at which it had been proved by radiography.

Dr. H. C. CAMERON had met with the condition not infrequently in adults. He suggests the use of a mercury tube, which in adults was successful in passing the pylorus.

Dr. G. A. SUTHERLAND commented on the early occurrence of the disorder, the first symptoms having appeared within a few hours of birth. He did not think a comparison between it and pyloric spasm very helpful, as the cause of the latter was unknown.

Mr. LOCKHART-MUMMERY said he was interested in the fact that the pyloric tube had been shown to curl up in the œsophagus. Investigations had shown that this was what happened when long slender tubes were used as with long rectal tubes in colonic lavage.

Dr. LANGMEAD, in reply, agreed that the cause of hypertrophic stenosis of the pylorus was unknown, and that no advance was made by comparing the condition under discussion with it. He intended merely to draw the comparison, thinking that the explanation of one, when forthcoming, might be true for the other. In answer to Dr. Weber, he thought that the diagnosis of the disorder by X rays with the exclusion of organic cause during life by œsophagoscopy was exceptional in so young a patient, and that the occurrence of symptoms within a few hours of birth was very rare.

Dr. R. C. JEWESBURY showed the Liver of a case of Cirrhosis in a child previously exhibited before the section and ascribed to alcohol. The cirrhosis was of the usual multilobular form, but the nodulation of the surface was not pronounced, and large areas were smooth.

Dr. E. A. COCKAYNE showed a case of

(?) *Raynaud's Disease and Necrosis of Nasal Bones.*

The patient was a boy aged 1 year and [illegible] months, who appeared normal up to the age of 3 weeks. At this age a bluish area appeared on the left hand, which was swollen. According to the mother, the centre of this came out as a "core." Shortly after this the child had an attack of diarrhœa and sickness. At 10 weeks there was a greenish-yellow offensive discharge from the nose, which had continued on and off ever since. The child was seen first at the age of 5 months. The bridge of the nose was very depressed and there was an offensive discharge. The fingers were blue and cold, with small septic areas on them, and the nails were deformed, and continued in this condition all through the summer. The child was fairly well nourished, but very susceptible to cold. There was a swollen red area just in front of the right ear, and a blue cold area with a necrosed centre in the middle of the cheek. The hands were blue and cold, and the child gave evidence of a good deal of pain in them. The fingers were thin, the skin blue and glossy, the nails deformed. Over the finger tips and nails there was much dry thickened epithelium. There was limitation of passive and active movements at the interphalangeal joints. The legs showed a blue mottling, and there were small scars on both legs. The toes were normal, but cold and blue. While under observation the finger tips had been almost black on two occasions, and on the dorsum of the left hand there had been a blue area with a dark centre of necrosed tissue. The Wassermann reaction in both mother and child proved negative on two occasions, in April and in July, 1919.

Dr. WEBER regarded the case as one of sclerodactylia, of which disease the early signs were the phenomena of Raynaud's disease. It should be sharply distinguished from Raynaud's disease proper.

Dr. SUTHERLAND said that Raynaud's phenomena should not be regarded as a disease; the condition sometimes improved by antisyphilitic treatment. In view of the nasal condition, he would not be deterred from advising antisyphilitic treatment by a negative Wassermann reaction.

Dr. COCKAYNE, in reply, said that antisyphilitic treatment had been employed, but without benefit.

Polio-encephalitis Affecting the Mid-brain.

Dr. J. C. SPENCE showed for Dr. F. J. POYNTON a case of Polio-encephalitis affecting the Mid-brain, with Involvement of the Pyramidal and Extra-pyramidal Systems.

The patient, a girl, aged 10 years, was a healthy, active child before the onset of the illness. The first symptoms arose in July, 1919, when she lost the use of her right arm. Later in the day her face became affected and appeared "to be twisted to the right." The child's mother stated that there was no accompanying loss of consciousness, vomiting, or signs of an acute feverish condition, and that she complained only of slight headache and loss of appetite. During the next few days she lost the use of her right leg, left leg, and left arm in turn, and her speech became affected. Within a week of the onset of the symptoms she was confined to bed unable to move her limbs, which were stiff and rigid, and spoke only in almost unintelligible monosyllables. She was very quiet and depressed, though subject to frequent emotional outbursts. She lay in this condition for a month before any change appeared. This was first seen in improvement in her speech and in return of the power to use her left arm, and was progressive up to her admission to hospital in October.

On admission she showed spastic paralysis of the right arm and leg. The arm was in a position of flexor rigidity, and there was a coarse tremor of the right hand. The tremor, absent during sleep or when the body was in a position of rest, was immediately brought into play by any emotional disturbance, attempt to speak, or carry out any muscular effort. On the left side the arm could be moved, but the movements were wildly ataxic, the leg was rigid, but there was slight movement at the hip- and knee-joints. Speech was slow, stuttering, and hesitating. There was no squint or ptosis. The pupils were equal, reacting normally to light and accommodation. The face was expressionless, and when the child was emotionally disturbed the loss of expression became more marked on the right side; but there was no true facial nerve paralysis. The right plantar reflex gave an extensor response, and there was an increased knee-jerk and ankle clonus on the right side. The left plantar reflex gave a more indefinite extensor response, difficult to elicit. There was no ankle clonus on the left side; the left knee-jerk was increased. No changes in sensation were detected. The fundi oculi were normal. The cerebro-spinal fluid was clear, sterile, and without any increase in cells or albumin content. Wassermann's reaction was negative. No abnormal physical signs could be detected in the heart or lungs. The urine was normal.

During the past two months the clinical picture had changed a little. While the right hemiplegia had persisted, unaltered except for a slight return of movement in the right leg and right arm, there had been distinct improvement in the tremor of the right hand, the ataxia of the left arm, the speech, and the control of the emotions. The ataxia, which on admission was very wild, had almost disappeared. She was no longer subject to the sudden and inexplicable emotional changes. A careful look-out had been kept for any signs of ocular paralysis. In December there was slight inequality of the pupils for about two weeks. During the past three weeks there had been a fine lateral nystagmus, but there had been no signs of third, fourth, or sixth nerve involvement.

Dr. W. MITCHELL SMITH said that if considerable deformity were to be avoided the limbs should be kept in a position preventing muscular relaxation of the affected muscles, and should not be removed at all from the necessary apparatus.

TUBERCULOSIS SOCIETY.

AT a meeting of this society held on Jan. 19th Dr. H. DE CARLE WOODCOCK, the President, being in the chair, Sir HENRY GAUVAIN gave an address upon

Surgical Tuberculosis Considered from the Standpoint of the Tuberculosis Officer.

Sir Henry Gauvain said that he hoped that he would not be thought presumptuous if he criticised the lack of interest which was shown by tuberculosis officers in this branch of tuberculosis work. Perhaps this arose in part because of the name, and because the public were accustomed to think that the subject came entirely into the realm of the surgeon and should not be treated by the specialists in tuberculosis. This idea was quite wrong. Although there were 10,000 deaths every year in this country from surgical tuberculosis, he had been struck, when he began practising, that there was not a single man who devoted his whole time to this form of the disease. He hoped that now that tuberculosis officers were appointed all over the country they would take an active share in this branch. The disease was caused by the same organism and called for similar methods of treatment, with additional local measures. The tendency of the operating surgeon was to treat the local trouble and then to dismiss the patient without undertaking general treatment. This was a mistake. In no variety of tuberculosis is the prognosis so good as in the surgical forms when adequate treatment is adopted, and operative interference is less and less required in proportion as other measures are timely. The tuberculosis officer is, however, of the greatest importance, because upon him devolves the work of early diagnosis and the after-care, both of which are so essential if success is to be attained. The need for surgical interference had become less and less, and at Alton not a single joint had required excision for some time past. There were three amputations during the last year, in all of which the necessity arose from sepsis introduced by previous surgical interference. Preservation of parts was aimed at, and not removal. Speaking of differential diagnosis, Sir Henry Gauvain said that he had had cases sent to Alton as spinal caries which proved to be rickets or scoliosis, congenital malformation of the spine, syphilitic disease of the spine, typhoid disease of the spine, or osteomyelitis. In hip disease the chief fallacies were pseudocoxalgia and streptococcal disease, or osteomyelitis of the femur. Pseudocoxalgia could be recognised by limitation of abduction and rotation, slight shortening, and some spasm. It caused some destruction of the end of the bone, with flattening of the head, and periostitis of the neck with increase of cartilage. There was no limitation of flexion, which was an early sign in tuberculous disease. The prognosis was good. In septic diseases the onset was almost invariably sudden, whereas in tuberculosis it was insidious. No doubt most cases of tuberculous bone disease needed treatment in a special institution, but the after-care should be taken over by the tuberculosis officer. Such questions as when to discard a splint, when to resume ordinary life, how much exercise to take, what occupations to take up, when a case may be considered quiescent, are all to be answered in the after-care period. Intensive post-graduate courses had been started at Alton, each lasting ten days, with lectures and facilities for practical work, and Sir Henry Gauvain invited tuberculosis officers to avail themselves of the opportunity afforded. There should, he said, be time and opportunity given by the authorities for such special courses of study. He also suggested that the establishment of a diploma in tuberculosis should receive consideration on the lines of that in radiology and electrology recently granted by Cambridge University.

A series of lantern slides were thrown upon the screen showing the hospital at Alton, the work carried on there, and the results of treatment in typical cases. A short discussion ensued, and the following resolution was passed:—

That representations be made to the various examining bodies with a view to the establishment of a diploma in tuberculosis.

THE MEDICO-LEGAL SOCIETY.

A MEETING of this society was held on Jan. 15th at 11, Chandos-street, W., Mr. R. HENSLOWE WELLINGTON, the President, being in the chair.

Proposed Formation of a Parliamentary Committee.

A proposal of the Council to the effect that a special Parliamentary Committee be formed, was discussed, and supported by Earl RUSSELL and other members. It was agreed unanimously that such a committee should be appointed to watch legislative proposals having medico-legal importance and to report to the Council and take such steps as may be found necessary. The Council was directed to take the necessary steps to form the committee.

Mr. DOUGLAS COWBURN read a paper entitled,

Some Experiences in a Coroner's Court.

After referring to the wealth of medico-legal material of enormous importance and great interest that becomes lost, for general purposes, owing to the inaccessibility of coroners' records, he detailed a number of cases presenting unusual if not unique features. A fatal case of poisoning by permanganate of potash in solution was narrated as of extreme rarity, as also a case of death from "status lymphaticus" without any ascertainable precedent fright, shock, or injury. The question was raised of the frequency of status lymphaticus as a cause of death apart from the administration of anæsthetics. Mention was made of two deaths during the administration of nitrous oxide gas, of one in which, while A.C.E. mixture was being given, an œsophageal varix ruptured, causing death by asphyxia from inhaled blood. It was pointed out that athletic alcoholics appear particularly unsuitable persons for certain anæsthetics and that the proportion of persons dying during the administration of anæsthetics and found to be the subjects of malignant disease was very notable. Mr. Cowburn, speaking as a coroner, emphasised: (1) the necessity always for a post-mortem examination; and (2) the fact that, especially in cases of death during treatment, relatives of the deceased were invariably satisfied when such an examination is made by an independent expert.

Mr. A. M. M. FORBES, also speaking as a coroner, agreed that post-mortem examination is necessary, but insisted that the "post-mortem" must be a "good" post-mortem.

Dr. F. G. CROOKSHANK alluded to one of Mr. Cowburn's cases—that of a lady who died, ten days after a fall, of intestinal obstruction unrelieved by operation, and of which the cause remained unexplained by a post-mortem examination—as probably belonging to that group of cases discussed by him, under the name of "delayed shock," in the Transactions of the Society for 1912–13 (Vol. X.). A number of such cases had from time to time been reported, but their occurrence.

although of great medical and legal importance, had been persistently overlooked.

Dr. B. H. Spilsbury very cogently supported Mr. Cowburn in regretting the loss of so much valuable material for teaching purposes, drew attention to the attempts made by the society to form a museum, and referred to the remarks made by the President in his recent address on the importance of founding the teaching of forensic medicine upon the wealth of experience afforded in London, though almost neglected.

Mr. A. S. Morley, speaking as an anæsthetist, said that in some cases it appeared to him that the surgeon rather than the anæsthetist should be summoned before the coroner in cases of death during operation.

The President, in expressing the thanks of the meeting to Mr. Cowburn for his valuable and instructive paper, referred to a dictum of the late Sir Frederic Hewitt concerning the responsibility always attaching to anæsthetists in the case of death during administration of an anæsthetic, and Mr. Cowburn replied.

London Association of the Medical Women's Federation.—A meeting was held on Jan. 20th at 11, Chandos-street, W., Dr. Emily Flemming, the President, being in the chair.—A discussion on Infant Welfare Centres was opened by Dr. Flora Shepherd, who described the organisation of such work. She said that in order to be successful each centre should be under the administrative control of the medical officer of health, and that the medical officer of the centre should send him monthly reports of the work done. Each centre should be responsible for all the work required, so as to avoid overlapping by health visitors sent by different authorities. No centre should be more than 20–30 minutes' walk from the homes, and not more than 30 children could be satisfactorily attended to in one session of two and a half hours. In a well-organised district there should be an attendance of 60–70 per cent. of all the births notified. She said that antenatal consultation should be entirely separate from infant welfare consultations.—Dr. Helen Robertson read a paper on Natural Feeding of Infants. She referred to some of the causes of inability to feed infants, and described how they could be helped by treatment at welfare centres. Among the points mentioned were nasal obstruction in babies, depressed nipples in the mothers, and bad health due to dental disease. She also referred to the fact that some babies got on well when fed only four times in 24 hours, and said that it was generally better not to wake them for feeding.—Dr. Alice King then read a paper on Artificial Feeding of Babies. She said that no rules could be given, as cases had to be judged on their own merits. She advised fresh cows' milk, boiled, and in estimating quantities she considered weight and size of much more importance than age. Fresh fruit juice, raw or underdone meat juice and cream should be added from an early age. Dried milk should be used as a routine when hygienic or atmospheric conditions were unfavourable. Dr. King found that dried milks were better tolerated than ordinary cows' milk by infants with digestive powers below the average, especially when prepared by the Béverat-de-Neven, as compared with the Hatmaker process. She preferred plain, desiccated milks, which could always be modified as required to those modified in preparation, such as glaxo, although many infants did well on the latter. Evidence showed that the antiscorbutic and antirachitic properties of milk were not decreased to any great extent by desiccation, but fresh fruit or vegetable juices should invariably be given with a dried milk diet.—A general discussion then followed, in which Dr. Ethel Bentham, Dr. Esther Harding, Dr. Clara Fitter, Dr. Janet Campbell, Dr. Grace Briscoe, and Dr. Octavia Lewin took part.

Devon and Exeter Medico-Chirurgical Society.—The annual meeting of this society was held at the Royal Devon and Exeter Hospital on Jan. 15th, Mr. R. Pickard being in the chair.—The following cases and specimens were exhibited:—Dr. R. V. Solly: A case of Oriental Sore in which various methods of treatment were mentioned. Also microscopic specimens of Anthrax from recent cases, Vincent's Angina, and a section of Liver from a girl, aged 19, who for many years had suffered from slight jaundice, with some cyanosis and attacks of pyrexia. The girl died from streptococcic septicæmia (proved by blood culture), and post mortem general peritonitis was found, with liver showing a nodular cirrhosis with marked bile staining of liver substance; microscopically there was a monolobular and intercellular cirrhosis with many new-formed bile ducts.—Mr. B. Dyball showed skiagrams of Perthe's Disease (osteochondritis juvenilis deformans) and of Rejuvenation of Diaphyses Tibiæ in a case of tubercular disease; a specimen of Lipoma of Cord and Varicocele, where the veins contained numerous phleboliths; a specimen of Tibia, which at first was diagnosed by a well-known London pathologist as osteitis fibrosa, but later the patient died from spindle-celled sarcoma, which was no doubt the original disease; a specimen of Carcinoma of Kidney and one of Congenital Cystic Kidney removed by operation.—Mr. A. C. Roper showed specimens of (1) Ruptured Tubal Gestation removed by operation, with well-formed fœtus; (2) specimens of (*a*) Adeno-carcinoma of Body of Uterus, and (*b*) Squamous Epithelioma of Cervix; (3) Renal Calculus with skiagram; (4) a completely detached Calcareous Fibromyoma of Uterus about the size of a hen's egg.—Mr. A. L. Candler showed a temperature chart of a case of Suppuration of Knee-joint, successfully treated by pumping ether into the joint.—Mr. N. F. Lock showed: (1) Specimen of Synovial Membrane, showing formation of many loose bodies. (2) Saccular Traumatic Aneurysm of Superior Profunda, producing paralysis of ulna, musculo-spiral, and musculo-cutaneous group of nerves. The aneurysm was removed intact and showed partially organised clot. (3) Specimen of Traumatic Aneurysm of Posterior Tibiæ also removed by operation.

Election of Officers.—The following officers for the ensuing year were elected:—President: Mr. B. Dyball. Vice-President: Mr. P. H. Stirk. Council: Dr. J. S. Steele Perkins, Mr. R. Worthington, Dr. C. N. Lovely, Dr. G. H. Hanna, Dr. Bertha Mules, and Dr. W. H. Date. Treasurer: Mr. R. Pickard. Secretaries: Dr. R. V. Solly and Dr. G. L. Thornton. Auditors: Dr. F. A. Roper and Mr. A. L. Candler. The following were elected members of the society: Dr. H. A. Cookson, Dr. Barrow, and Dr. J. Allen.

Edinburgh Medico-Chirurgical Society.—At a meeting of this society held in Edinburgh on Jan. 21st Dr. John Eason read a paper entitled "An Inquiry Regarding the Age and Sex Incidence of Pernicious Anæmia," and quoted first the views of various authorities to show that it was generally held that the disease was one mainly met with in middle life. He pointed out a number of defects in all available statistics, and particularly that no account was taken of the age-distribution of the population. Eliminating the various fallacies, a careful analysis of 600 cases treated in Edinburgh hospitals during the last 21 years showed that the incidence of the disease steadily increased with age, and was distinctly more common in females than in males. In men the relative maximum was reached at the age of 69, whereas in women it was attained about the age of 50, the figure for later years remaining about the same.—Dr. John D. Comrie read a paper on Scurvy, based upon cases observed while acting as consulting physician to the British Forces in North Russia. After a brief historical note, the lecturer stated that scurvy was prevalent in North Russia amongst the inhabitants every year during the winter months, and that the favourite treatment there adopted was the administration daily of two pints of fresh milk. Many cases were to be seen in the civil hospitals and among Russian prisoners, but the disease was very rare amongst the British troops. A careful analysis of cases showed that approximately 4·7 months of defective diet were necessary before the disease made its appearance, but that this period might be considerably shortened by other diseases. Of all symptoms, hæmorrhage was the commonest, particularly the purpuric rash on the legs. In half the cases also there were deeper hæmorrhages into the muscles, especially over [illegible] exposed to pressure. Bleeding into a joint provided one of the most troublesome features of the disease, and was particularly prone to be followed by the formation of adhesions. Depression, pain in the head and legs, and the characteristic condition of the mouth were other prominent symptoms. Sudden death was not at all uncommon. Effusion into the pleura was frequent; brown atrophy of the heart was a characteristic post-mortem finding. The blood changes were those of a secondary anæmia, with a lymphocytosis. Under suitable treatment the hæmorrhages became rapidly absorbed and complete recovery (with the exception of contractures) usually took place in about a month. Careful investigation of various vitamine-containing articles of diet showed that cases recovered most rapidly which were treated with soured milk, while fresh meat and fresh lime-juice also gave excellent results. Preserved lime-juice did not prove satisfactory.—Mr. J. W. Struthers read a paper on Perforated Gastric and Duodenal Ulcer, quoting from personal experience some 90 recent cases. Under present conditions he said that the mortality in cases of perforation was approximately about 20–25 per cent. In a large proportion of those observed symptoms pointing to ulcer had been present over a long period, but in others the onset was sudden or the antecedent symptoms very mild. Apart from the danger of perforation, ulcer was also attended with the possible sequence of pyloric stenosis or gastric cancer. Discussion was invited as to whether more cases should not be submitted for surgical treatment in the early stages than had hitherto been customary, as it was only by treatment prior to perforation that a lessened mortality could be expected.

Reviews and Notices of Books.

PHYSIOLOGICAL PRINCIPLES IN TREATMENT.

Fourth edition. By W. LANGDON BROWN, M.D., F.R.C.P. London: Baillière, Tindall, and Cox. 1919. Pp. viii. + 427. 7s. 6d.

IT is an axiom—or a dogma—that medicine is the better for association with physiology. But different opinions are held as to the method of association. Some physiologists have clamoured for perpetual access to the patient, forgetting the human complexities of the art of medicine and surely unmindful of the true progress of their science. Others have not been content to throw physiology neck and crop into the technological mill of the wards and would have those parts of physiology which are obviously germane to medicine taught and brought into practical use by the clinicians. The question is, indeed, part of the debate as to whether the segments of the medical curriculum are to overlap upwards or downwards. It is much to be hoped that the introduction of whole-time teachers of medicine and surgery in the London schools will finally demonstrate the superiority of the latter arrangement, and will create a body of clinical teachers with the necessary leisure to keep themselves properly acquainted with the progress of natural knowledge and thus desirous to apply to practice such parts of it as they find useful. But medicine and surgery after all consist of clinical problems which must be solved by clinical methods.

In the present volume Dr. Langdon Brown shows how the desirable combination of physiological knowledge and clinical practice may be achieved under less favourable conditions than we may now anticipate will prevail. Four editions in 11 years prove that his book has been acceptable and useful, and the atmosphere of practical medicine which he creates out of physiology is most successful. The work does not pretend to be a complete systematic treatise; it is really a series of essays, grouped on a clinical rather than a physiological basis—a plan which has the immense advantage that each chapter is plainly the result of practical personal experience. The physiologist could find a good many small matters for debate if he were on the look-out for them; how, for instance, constipation can raise blood pressure "mechanically" (p. 359), how potassium iodide ferrets out the toxins which lurk in lymph spaces (p. 360). But he would also find a wealth of interesting clinical experience which, if not altogether based on the sort of evidence he is accustomed to ask for, is not the less credible; as the author points out, observations made in the laboratory are not necessarily more correct than clinical evidence. The present edition has been revised throughout; the chapters on diabetes and vitamines are mostly new, and it is not the author's fault that acidosis has jumped off on another track (and perhaps run away altogether) since he wrote his account of it.

GERIATRICS.

A Treatise on Senile Conditions, Diseases of Advanced Life, and Care of the Aged. By MALFORD W. THEWLIS, M.D. With introductions by Dr. A. JACOBI and Dr. I. L. NASCHER. London: Henry Kimpton. 1919. With 13 illustrations. Pp. 250. 15s. net.

THIS book differs considerably from the treatise by Dr. Nascher, the second edition of which was reviewed in THE LANCET of August 9th, 1919. Each chapter forms a kind of clinical lecture in itself, plentifully illustrated by short notes of actual cases and written in an easy style, forming, it may fairly be said, interesting and even cheerful reading for the busy practitioner. The chapter (III.) on "The Value of Age" refers to excellent work done by many famous persons, past and present, when well advanced in age. The headings of two other chapters are respectively: "Work for the Aged" and "Keep Senile Cases Out of Bed." These two headings give a clue to much that the author tells us in regard to the management of the aged. We cannot better illustrate his method than by quoting more or less at random from the text: "*Staying in the harness* is the real secret of bringing about the best results from our aged minds. ...... The responsibility of work helps them beyond measure." "We should provide some work for our aged friends and relatives. ...... It is wrong to think that, because a man has worked hard all his life, he should not work any more. ...... Never change an old person's mode of living." The amount of fat required in the diet in old age is apparently but little less than that required in maturity, whilst the protein and carbohydrate factors are much less. "An excessive amount of salt is detrimental to the kidneys, but the spices, acid, and sugar are beneficial in old age." In senile bronchitis "the discharge, no matter how profuse or fœtid, should not be checked, as this may cause paralysis and suffocation." "Aged persons should avoid retaining urine too long," and when they empty the bladder they should take care to do so as thoroughly as possible, even if thoroughness necessitates the expenditure of a few extra moments of time. The author quotes the saying, "In maturity nature tends to cure, while in senility nature will kill." He refers to a fatal case in which he thinks that an attack of cardiac pain was mistaken for gastritis, and in which nitroglycerine might have saved the patient's life. The use of alcohol as a drug is commended in the following words: "Alcohol forms one of our best weapons in treating the aged, especially when there is much debility. I usually administer it to its full physiological action—that is, until the cheeks become red and the mouth becomes parched. In pneumonia, or even in some forms of chronic nephritis where there is extreme weakness, it is of value." The habit of taking a certain amount of alcohol daily should, according to Dr. Thewlis, like other old habits, not be tampered with in aged persons. We suggest that the danger of cutting off morphine altogether in senile patients who are accustomed to it might have been referred to here.

Here is another piece of counsel. "We must not forget that it is not always the object in the aged to heal or correct an abnormality. Frequently, as with fistula, nature seems to use the disease to rid the system of some toxin, and as long as it is not disturbed they remain in good condition." In regard to operations on senile patients the author again urges the importance of getting them out of bed as soon after the operation as possible. His keynote in geriatrics is: "Keep senile cases out of bed." Readers need not agree with all the author's views, but all who study the book will be compelled to recognise its shrewdness and practical wisdom.

THE PATHOGENIC BACTERIA AND PROTOZOA.

A Text-book for Students of Medicine and Physicians. Ninth edition, revised. By JOSEPH MCFARLAND, M.D., Sc.D., Professor of Pathology and Bacteriology in the University of Pennsylvania, &c. London and Philadelphia: W. B. Saunders Company. 1919. With 330 illustrations, a number in colours. Pp. 858. 21s.

LIKE other excellent and now numerous text-books on bacteriology which have appeared in America during the past twenty years, this work is distinguished by definiteness of aim and methodical and systematic treatment of subject, while the good style in which it is produced is also what we have been led to expect. The purpose of this book is set forth in the title, and is kept rigidly in view. The author avoids the danger of the incorporation of excessive material, and has indeed reduced somewhat the size of the book. The particular features and merits of the book have been fully set forth in reviews of previous editions, so that, as there appears to be no such considerable change in the present volume as occurred when the pathogenic protozoa were added to the subject matter of the book, it suffices to say that the work satisfactorily fulfils the purpose for which it was written. The section on anterior poliomyelitis, which was somewhat inadequate in the 1912 edition, now contains Flexner and Noguchi's cultural results, but little if any work done since 1913 finds a place. The chapter on relapsing fever groups together the European, African, and other forms, and gives a good general view of the subject, while Leishman's observations, formerly omitted, are now included, and there is an interesting appendix describing the vectors of the spirillum. The work on infective jaundice and on rat-bite fever is well epitomised. The chapter on yellow fever will probably require considerable alteration in the next edition, as the recent work of Noguchi, if confirmed, will revolutionise our knowledge of the ætiology of the disease. The anaerobic infection of wounds has become of great importance during the war, and under the heading of gaseous œdema some of the recent work on the organisms found in this condition has been incorporated, but there does not appear to be any notice of the effect of prophylactic treatment of tetanus on the character of the subsequently developing disease, nor of the experience gained with regard to vaccination in typhoid, cholera, and dysentery. The section on influenza shows no influence of recent experience, but the results of this are perhaps too uncertain to be incorporated in a text-book.

Though this edition is possibly not brought up to date as completely as it would have been if produced in quieter times, this detracts but little from its merits as a text-book, and it can be confidently recommended to the student.

PSYCHIATRIC-NEUROLOGIC EXAMINATION METHODS.

With Special Reference to the Significance of Signs and Symptoms. By Dr. AUGUST WIMMER, Director, St. Hans Hospital, Roskilde, Denmark. Authorised translation by ANDREW W. HOISHOLT, M.D., Professor of Psychiatry, Leland Stanford Junior University, San Francisco, California. London: Henry Kimpton. 1919. Pp. 177. 10*s*. 6*d*. net.

THIS slender volume is intended to be a guide to the student and practitioner for his examination of nervous and mental cases. It contains a more or less systematised semiology, on a small scale, of the nervous and mental affections of the commoner sort, arranged by mechanisms; on the nervous side we have external habitus, organs of sense, speech, motor disturbances, abnormal movements, paralyses, sensation, reflexes, and so on; on the mental, attention, apprehension, orientation, sense-deception, fallacious ideas, imperative ideas, memory—to name but a few of the sections. It is really becoming a difficult matter to compress the normal and pathological physiology of the nervous system, and the normal and pathological psychology of the mind, into a few pages, though the author has managed his task with some degree of success. Of the few (nine) diagrams which the book possesses some are altogether useless; we feel many more should have been included, or none at all. Occasional unfamiliar expressions in the translation pull the English reader up; the cervical enlargement is called the "cervical intumescence," and "baroque physical influences" seem to have wandered in from architecture.

SWANZY'S HANDBOOK OF THE DISEASES OF THE EYE AND THEIR TREATMENT.

Twelfth edition. Edited by LOUIS WERNER, M.B., F.R.C.S.I. London: H. K. Lewis and Co. 1919. With nine coloured plates and 273 illustrations. Pp. 671 + xviii. 22*s*. 6*d*. net.

To keep a standard text-book, such as this, up to date without unduly adding to its bulk is a feat which has been very successfully accomplished by the editor. It contains nearly all that it is good for a student to know until he begins to find things out for himself. Moreover, it is no patchwork such as some text-books which run through many editions are apt to become, but can be read through usefully and pleasantly. Taking for granted a knowledge of the anatomy and physiology of the normal eye, the book starts with a short chapter on optical structure and functional examination, and another on the use of the ophthalmoscope. The student is recommended to read these and the chapters on elementary optics and refraction immediately on joining the ophthalmic hospital or department. The rest of the book gives a clear account of the diseases which affect the various parts of the eye, including the ocular symptoms liable to accompany focal and diffuse disease of the brain and of the spinal cord. The weak side of the book concerns treatment. We look in vain for needed information on the substitutes for atropine, on the different forms of silver salts, and on the action of local anæsthetics. A short chapter on the therapeutics of the eye would be valuable in future editions.

The chief improvements in this edition over former ones are in the chapter on diseases of the cornea and in the account of the exact knowledge of the localisation of lesions of the occipital lobe, gained through the experience of the war. And here some of the more difficult points might, we think, have been omitted or accompanied by references to other authorities. For instance, the so-called spiral fields of neurasthenia should not now be mentioned without a reference to the work of A. F. Hurst, who attributes them entirely to suggestion. Again, it may be perfectly true to say that night-blindness is a result not of defective light sense, but of imperfect adaptation; but this statement conflicts with other authorities, and should therefore be made, not dogmatically, but with some indication of where a reasoned argument on the subject may be found. These, however, if defects, are minor ones, and we can whole-heartedly recommend the book to students. The coloured illustrations drawn by the editor are a valuable feature.

BING'S COMPENDIUM.

Kompendium der Topischen Gehirn- und Rückenmarksdiagnostik. By ROBERT BING, a. o. Professor an der Universität Basel. Vierte neu durchgesehene Auflage. Berlin: Urban and Schwarzenberg. 1919. Mit 97 zum Teil mehrfarbigen Abbildungen. Pp. 235. M.16; geb. M.20.

Professor Bing's well-known compendium is much improved from its second edition, which we reviewed in 1911. It is larger and more inclusive, while its features of clarity of expression and of diagrammatic representation are as noticeable as before. Going over the volume critically we meet with several indications that the author is not abreast of the most recent neurological research in countries outside Central Europe. Professor Bing cites the old criteria of total transverse lesions of the cord without apparently recognising that this is a chapter which war experience has completely rewritten. His description of the pathological reflexes shows that he fails to regard them as parts of mesencephalo-spinal mechanisms revealed by interference with cortico-spinal function—a point of view which is not merely more instructive, but calculated to bring them all into line in a way never hitherto attempted. He speaks of spinal automatisms, as we know them, as "flight or defence reflexes," an expression already out of date. The surprising attitude is adopted that tremor, chorea, and athetosis are the result of irritation of the pyramidal path in the crus—a definite error. Professor Bing describes a lenticular syndrome consisting of contralateral paresis in face, arm, and leg, exaggerated deep reflexes, difference in the pupils, and atrophy of the opposite limbs and some sensory changes. Whatever this syndrome may be, it is not that of the lenticular nucleus. He states that bilateral arterio-sclerotic lesions of the basal ganglia cause permanent incontinence of urine with an automatic bladder, but it seems incredible he should be unaware of much less debatable symptoms associated with such a pathological basal lesion. He regards xanthochromia of the cerebro-spinal fluid as a sign of extramedullary spinal tumours, yet it occurs in other quite different spinal conditions.

Apart from the revision which these and other criticisms may justify, Professor Bing's compendium will be found reliable and useful as a practical aid to neurological diagnosis.

JOURNALS.

Journal of Physiology. Edited by J. N. LANGLEY, Sc.D., LL.D., F.R.S. Vol. LIII., Nos. 3 and 4. Cambridge University Press. Pp. 147–271. 10*s.*—Vaso-motor Centres. Part II.: Observations on the Action of Strychnine, by J. N. Langley. The experiments were made on decerebrate curarised cats. Strychnine is for convenience spoken of as causing a rise of blood pressure by stimulating nervous centres, although it is still an open question whether it stimulates or only increases the responsiveness of centres to external stimuli. The spinal cord was stimulated by placing electrodes flat on the surface of the cut lower end of the cord. Currents rather strong to the tongue were required to produce a marked rise of blood pressure. Strychnine up to a certain amount increases the rise of blood pressure caused by submaximal stimulation of the spinal cord. Above this small amount it causes a decrease of the effect of cord stimulation, but complete absence of stimulation is not caused by 60 mg. The effect of strychnine on the bulbo-spinal animal closely resembles its effect on the spinal animal. The maximum rise of blood pressure is caused by a small amount; after this amount has been given, further injection causes a slight and decreasing rise. The differences are, in the main at any rate, due to the higher central tone and better circulation in the bulbo-spinal animal; the later injections of strychnine cause a much more marked primary fall of blood pressure and partial recovery. The form of the blood-pressure curve with injections of strychnine, after the first, depends on the balance of several factors—viz., the remaining excitability of the central vaso-constrictor centre, the degree of paralysing action on central tone, and the degree of peripheral action, which is probably a weakening of the heart beat. Central vaso-dilator stimulation plays little part in the form of the curve, though in the dog there is with the first injection more or less flushing of the bucco-facial region. Strychnine causes an apparently maximum rise of blood pressure after excision of the suprarenal gland and it causes some rise of blood pressure after removal of the abdominal viscera, and it is inferred that its action on cutaneous vessels, apart from local spinal areas, as on visceral vessels, is one of constriction. Strychnine does not convert vaso-inhibitory into vaso-constrictor impulses. Strychnine after a large dose of ergotoxin causes a trivial fall of pressure, probably of peripheral origin. In anæsthetised animals strychnine, after causing a primary fall, may cause a slow rise of blood pressure above the original height, suggesting stimulation above the level of the spinal bulb.—The Neutrality of the Blood, by W. M. Bayliss. The author uses neutral red as an indicator for the determination of the hydrogen-ion concentration of arterial blood. This substance, within certain degrees of ion-concentration, gives a regular series of changes in tint from crimson to yellow. Intravenous injection of acid in sufficient quantity to neutralise half the bicarbonate in the blood does not increase the hydrogen-ion concentration of the plasma. The chief mode of compensation is by increase in pulmonary ventilation and consequent decrease of carbon dioxide in the blood. Renal excretion of acid and ammonium production in the liver do not appreciably come into play in short experiments. Injection of alkali is not so easily neutralised. The chief agent in this case appears to be the excretion of alkaline urine. The proteins of the plasma play no appreciable part in the maintenance of neutrality between the limits of hydrogen-ion concentration possible in the living organism. No evidence was obtained either that sodium bicarbonate, serum-proteins, or both together convey carbon dioxide from the tissues to the lungs. Thus the only function of sodium bicarbonate in the blood is to regulate the hydrogen-ion concentration, while, under normal conditions, the only function of the proteins is to give a colloidal osmotic pressure and a moderate degree of viscosity to the blood.—Experiments on Acclimatisation to Reduced Atmospheric Pressure, by J. S. Haldane, A. M. Kellas, and E. L. Kennaway. The characteristic physiological effects of lowered atmospheric pressure at high altitudes were proved by Paul Bert to be due, not to lowering of the mechanical pressure of the air, but solely to lowering of its oxygen pressure and consequent inefficient oxygenation of the blood. The present experiments were undertaken in connexion with a projected expedition to the higher peaks of the Himalayas. Preliminary experiments in a closed chamber were made in order to observe the effects of exposure for some time to a pressure of half an atmosphere on respiration, pulse, cyanosis, mental and sensory symptoms, capacity for muscular work. After half an hour there was practically no discomfort. The symptoms of the anoxæmia in these and more prolonged and varied experiments are described and discussed. These symptoms appear to be less marked than when the alveolar oxygen pressure is reduced to the same extent by simply reducing the oxygen percentage in the air breathed. The severity of the symptoms is not always proportional to the blueness of the lips and face, and particular symptoms vary a good deal. During anoxæmia there is a very marked diminution in the acid excreted by the kidneys and a less marked diminution in the excretion of ammonia. Partial acclimatisation to reduced atmospheric pressure was obtained by discontinuous exposure to progressive diminution of pressure; but this partial acclimatisation was apparently due almost entirely to increased inward secretion of oxygen by the lung epithelium. A mere increase in respiration or circulation cannot relieve the anoxæmia, and the conclusion is drawn that the supposed slight acidosis of acclimatisation is in reality only an incomplete compensation of a continued alkalosis due to the increased breathing caused by the anoxæmia.—The Thymus and Tetany, by T. J. Honeyman. Extirpation of the thymus along with the parathyroid in the guinea-pig does not modify in any way the onset of symptoms of tetania parathyreopriva, and it appears unlikely that the thymus secretes or contains any substance capable of producing tetany. —The Hyperglycæmia of Asphyxia and the Part Played therein by the Suprarenals, by C. H. Kellaway. It has recently been denied that the suprarenals play any part in producing the hyperglycæmia of asphyxia. Most of the observations were made on non-anæsthetised cats in which the preferential dilatation of the pupil was used as an index of the output of adrenalin and the degree of asphyxia carefully regulated. It was found that the acceleration of adrenalin secretion and the hyperglycæmia caused by asphyxia both depend on a complex of effects. These results are discussed, and the author concludes that they are mainly due to lack of oxygen, excess of CO_2 playing at most a subsidiary part. In both cases the main effects, in anoxæmia of ordinary severity, are due to action on the central nervous system, the splanchnic nerves providing the paths of impulses. When the splanchnics are cut severe anoxæmia still elicits both effects by peripheral action. The increase of blood sugar is only in part caused by the accelerated output of adrenalin.—Carbohydrate Metabolism in Ducks, by G. B. Fleming. Respiratory exchange is influenced by the diet in the same way as in mammals. Injection of adrenalin or removal of the pancreas produces hyperglycæmia. Within half an hour after the injection of adrenalin the respiratory quotient is raised and during the next half hour it falls. The rise in the respiratory quotient after the injection of adrenalin in the fasting animal indicates a mobilisation of carbohydrate, but the persistence of hyperglycæmia after the R.Q. has fallen suggests that adrenalin may cause inhibition of the pancreatic internal secretion. Neither ligature of the portal veins, nor excision of the pancreas, nor the combination of these procedures causes a rise in the R.Q., even when glucose is administered. The evidence indicates that in pancreatic diabetes the tissues are unable to utilise carbohydrate rather than that the liver is the sole seat of metabolic error.—Action of Substances Influencing the Carbohydrate Metabolism in Experimental Beri-beri, by

Casimir Funk. Based on the assumption that the anti-beri-beri vitamine plays an important rôle in the carbohydrate metabolism, a series of substances known to influence this metabolism were investigated. Their action on the blood sugar, liver, glycogen, and amino-nitrogen of the blood was studied, as well as their influence on the onset of beri-beri, duration of life, and loss of weight when administered to pigeons fed on polished rice. Glucose produced practically a disappearance of glycogen, a diminution of blood sugar both in normal controls and in rice diet. In feeding experiments phlorizin seemed to hasten the onset of the disease and increase the loss of weight. Adrenalin has no marked effect on the carbohydrate metabolism; pituitrin was found to be without effect. In feeding experiments only one animal out of six developed beri-beri, and all animals died early with great loss of weight. Thyroid gland produced a considerable sugar increase in the rice series. Hyperglycæmia occurs in pigeons on vitamine-free diet.—Experiments on the Internal Secretion of the Sexual Glands, Especially on Experimental Hermaphroditism, by Knud Sand. The author gives a short account of some experiments which form part of a large monograph published in Danish (1918). Steinach (1911–13) produced transformation of sexual characters in mammals by exchanging the sexual glands, and in 1916 he succeeded in producing a somatic and psychical hermaphrodite animal by subcutaneous ingrafting of both kinds of sexual gland at the same time and on the same infantile castrated male animal. The author's experiments on masculinisation and feminisation were made on rats and guinea-pigs mostly operated on within the first month of their lives. Experiments on transplantation of testes and ovaries are cited. In the ovary experiments the hormone-supplying tissues seem to be the follicles, the theca-lutein, and corpora lutea, and they are able under different circumstances to supply the place of one another in their influence on the female "accidental" (secondary) sexual characters. In experiments on rats on masculinisation hypertrophy of the clitoris was produced, besides the somatic reactions observed by Steinach. Castration of the experimental animal is a condition sine qua non for the ingrafting and efficiency of the heterological gonads, the transplanted organ perishing if castration is omitted. Simultaneous transplantation of a testis and an ovarium on the same castrated infantile animal (guinea-pig) resulted in somatic hermaphroditism combined with a decided bisexualism of the psycho-sexual character, in that the animal showed momentary changes from female to definite male character, according to the animals with whom it was brought into contact. Thus it seems possible to produce an artificial hermaphrodite through simultaneous transplantation of male and female sexual glands on an infantile animal. Experimental hermaphroditism was produced by an artificial ovario-testes method—i.e., by placing the ovaries in the middle of the testes and leaving the latter in their natural position. The ovary grows, matures, and functions well within the testes.—Note on the Permeability of Red Corpuscles for Glucoses and Glucosamine, by Shuzo Kozawa. In man the red corpuscles are easily permeable for blood sugar and in the dog slightly. In the hyperglycæmia of diabetes the volume of the red corpuscles is increased. The sugar content of the reds never exceeded that in the medium in which they were immersed. Human reds are permeable to glycosamine, but those of rabbit, dog, and horse are impermeable.—A Simple Definite Test for Ascertaining the Existence of Functional Cardiac Calcium, by W. Burridge. Hearts stopped in diastole following treatment with oxalates or citrates show a profound and definite change in their mode of reaction to a 5 per cent. potassium chloride solution, due to a loss of the normal functions of calcium. The changed reaction to the potassium solution has never been found in a beating heart, hence it is concluded that every beating heart must contain functioning calcium. It is only when we find this changed reaction that we are justified in assuming the absence of functional cardiac calcium.

Tubercle. A Monthly Journal Devoted to all Aspects of Tuberculosis. Vol. I., No. 4. January, 1920. London: Bale's Medical Books and Journals. 25*s.* per annum.—The January number begins with a paper by Dr. Otto May on Some Aspects of the Tuberculosis Problem in Life Assurance, in which the relation of family history of tuberculosis and other conditions to insurance are discussed. Among these conditions is exposure to mass-infection, and a very remarkable case is related on the authority of Dr. J. D. Cochran. A crew of seven, one of whom suffered from cough and spit, embarked on a Shetland fishing-boat and occupied the cabin, 14 ft. square by 6½ ft. high, for the season (May to September, 1909). The whole crew with a single exception died of consumption, and four of them, not including the infecting case, are known to have died within two years—i.e., by the spring of 1911. Nevertheless, Dr. May does not regard contact as necessarily increasing the risk in life assurance; the "contact case" is to be considered in respect of family and personal history, &c., and if these are favourable contact is ignored, otherwise a debt small or large is put on the policy. The paper includes charts showing the ratio of deaths from tuberculosis to total deaths at various ages. These exhibit the well-known heavy mortality in early life and its rapid fall in adult life, which is paralleled by the decreasing risk in assured persons with a previous history of tuberculosis.—Abstracts dealing with the results of artificial pneumothorax treatment form a special feature of this number. According to Sachs's analysis of 1108 American cases, negative results obtain in nearly half, palliative in nearly one-third, while apparently durable results occur in over one-fifth. Considering that the negative results include failures to establish the desired pneumothorax these figures must be regarded as very encouraging, and still better results may be obtained by more experienced selection and technique. In an account of 63 cases observed by Dr. Parfitt and Dr. Crombie of Gravenhurst, Ontario, prominence is given to mishaps, and valuable deductions are drawn therefrom as to prevention, diagnosis, and treatment. These authors, like Dr. Sachs, regard the method as the most effective available for progressive cases (particularly unilateral) in any stage, ordinary hygienic treatment having already failed.—A critical review on industrial phthisis further emphasises the work of Brownlee and points out that the separation of the factors in the causation of tuberculosis in factories is not merely an academic one. "Prevention of the inhalation of dust will be effective in regard to general respiratory diseases and to tuberculous silicosis, but will leave the greater amount of industrial tuberculosis untouched unless the means used to prevent dust inhalation happen to improve general ventilation."—Another critical review deals with State aid for sanatoriums, with special reference to the adaptation of army hutments.—The first of a new series of articles on the tuberculosis classics is devoted to Cornet's scrofulosis, and there follow reports of meetings of the Tuberculosis Society and other gatherings, together with notes on lectures delivered at Brompton Hospital and general news.

Ophthalmological Society of Egypt, Bulletin of 1919.—Lieutenant-Colonel H. L. Eason, in a paper on the Epidemic of Ophthalmia among Napoleon's Troops in Egypt in 1799–1801, and of Ophthalmia among British Troops and among Enemy Prisoners in the Egyptian Expeditionary Force, 1916–1918, retells the story of the epidemic of "Egyptian ophthalmia" of Napoleon's time, now generally recognised as having been not trachomatous but an acute purulent ophthalmia such as is seasonal every year in Egypt. The interest of the paper lies in the conclusions drawn from the experience of the recent campaign. Notwithstanding the almost universal prevalence of trachoma among the natives of Egypt, it appears that the infectivity of trachoma among soldiers of clean personal habits is almost negligible, and that ophthalmia of any sort is not a serious danger to an army with modern standards of sanitation. Several other papers are published, showing that the society is very much alive.

FRENCH SUPPLEMENT TO THE LANCET

Under the Editorial Direction of
Professor CHARLES ACHARD, PROFESSOR OF PATHOLOGY AND THERAPEUTICS IN THE UNIVERSITY OF PARIS,
AND
Dr. CHARLES FLANDIN, D.S.O., CHEF DE CLINIQUE A LA FACULTÉ DE PARIS.

SOME APPLIANCES FOR THE EXAMINATION OF THE NERVOUS AND MUSCULAR SYSTEMS.

BY DR. JEAN CAMUS,
PROFESSEUR AGRÉGÉ OF THE MEDICAL FACULTY IN PARIS; MÉDECIN DES HÔPITAUX.

THE manifold demands made by the war have forced doctors and physiologists to invent new methods or to adapt old ones to suit new wants. The Grand Palais, a huge centre for functional and professional re-education, which at some periods has been treating more than 3000 wounded men daily, has been the seat of certain physiological investigations which have led to practical applications. The main branches of these researches have concerned themselves with dynamo-ergography, vaso-motor reactions, tremor, and the selection of aviation candidates.

1. *Utilisation of Dynamo-ergography in the Study of Disablement.*

Since Marey, the graphic method is the classic way of studying the various muscular movements, and since Mosso, the results of ergography have been well established. It is able to furnish valuable information about work and muscular fatigue, and with many modifications it has been the origin of many publications.

It seemed to me to be interesting to make use of it to gauge the disability of wounded men treated by physiotherapy methods at our centres. These disabilities can certainly be ascertained by instruments for measuring, and I have already described some.[1] But the graphic method seemed also calculated to give most valuable information, as it allows us to measure and register the work done by wounded limbs before, during, and after a time of treatment.

At first I thought of connecting a registering attachment to the large number of mechanotherapy apparatus already in our possession, and by their means registering the work and the fatigue curve of the wounded. But I feared that the transport and adaptation of the registering attachment to various apparatus would meet with great practical difficulties, and I preferred to ask the Boulitte firm to set up two dynamo-ergographs,[2] one of which was to register most of the greater movements of the limbs and the other the movements of the hands and fingers. It was a matter of registering the main natural movements of the limbs, such as flexion, extension, &c., and not the more or less complicated occupational movements, so as to be able to estimate the functional, and not the working, value of a limb.

The general dynamo-ergograph which I have had set up consists quite simply of a lever, the movements of which are transmitted to a pulley to which weights are attached. On pulling the lever the movement of the limb raises the weights, whilst two counters add up the successive elevations of these known weights, so that the total work done is immediately known at the end of the experiment. At the same time the amplitude and number of contractions and the fatigue curve can be seen by means of the registering apparatus. The weights are adjusted to suit the muscular strength of the patient.

The arm of the lever being variable at will, this instrument allows us to ascertain not only the total effort but also its physiological quality by expressing the effort which depends on the arm of the lever and the distance traversed.

The registration of the curve of fatigue is accomplished by means of a manipulator barrel and a registration drum. The apparatus allows us to register the flexion and extension of both the superior limbs, together or separate, and in the same way those of the two inferior limbs and the two feet. The pressure of the hands is registered by means of a bulb firmly grasped in the fist and placed in connexion with a Marey barrel.

The special dynamo-ergograph for the hand and wrist is based on the same principles, and like the general dynamo-ergograph it has one counter which adds up the successive movements of the weights and another which counts the number of movements. This apparatus allows us to register the movements of the hand, wrist, and fingers in positions intermediary between complete pronation and complete supination. It also allows us to register abduction, adduction, and to take the pulse, and that on either side.

These two apparatus allow us (1) to establish the quality of the movements of the limbs, their strength, rapidity, and amplitude, the work done and the fatigue caused; (2) to follow the progress made during the treatment; (3) to detect malingering; (4) to evaluate functional disablement for work with a view to pensions and allowances.

The occurrence of malingering has often to be considered in the case of wounds as well as of industrial accidents. The diversity of the movements and their registration are bound to make malingering difficult. In the whole course of the exercises the malingerer must inevitably introduce discrepancies in force, amplitude, and duration, and these discrepancies become proofs against him. Moreover, with the help of a simple attachment it is easy to produce electric excitations in the course of the exercises, which allow of a further judgment as to the value of the muscular contractions.

Since Mosso it is well known what a distinctive appearance and individuality the ergographs possess and how hard it is for a man to simulate a fatigue curve when the registering apparatus is withdrawn from sight. But it is important to add that inconsistencies in the ergographs are not always a proof of simulation or of want of goodwill on the part of the patient. When there is pain at the beginning of the work, or when it appears as a result of the work, it disturbs the appearance of the ergographs. It is therefore necessary to investigate clinically under different conditions whether the sensitiveness of the wounded men who are tested has been affected.

The uses of the appliance which we have just briefly described are fairly numerous. In particular it can be seen how it can serve to study the comparative value of prosthetic appliances by examining the quantity and quality of the muscular work

obtained by their aid. It can obviously also be used to estimate the results of surgical operations by registering the movements before operation and some weeks after it. Following out this idea, MM. Nepper and Vallée have studied three different cases in our laboratory, some record of which may be found in Dr. Valée's thesis.[3]

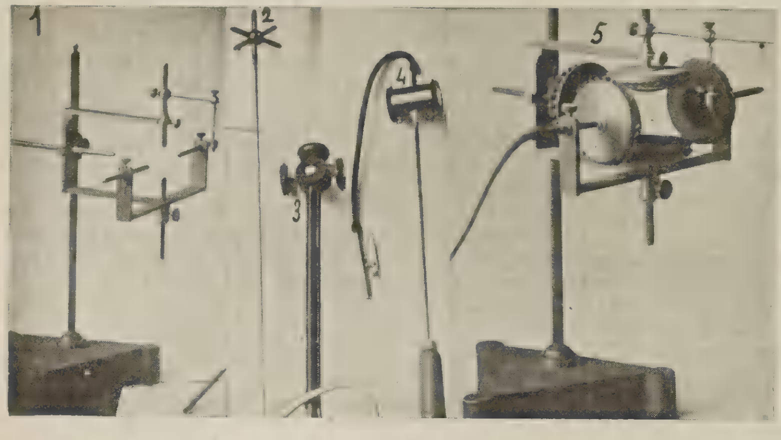

FIG. 1.—Various appliances for the study of tremor. *1*, Apparatus to be used with the drums *3* and *4*. *2*, Apparatus in which the hand or the rod *2* is introduced.

2. *Study of Vaso-motor Reactions.*

Wounds are a frequent cause of vaso-motor troubles, and, moreover, the variations in vaso-motor reaction deserve to be studied as evidences of the degree of an individual's susceptibility to emotion in various circumstances, in the case of patients where trephining has been resorted to, candidates for the flying service, &c.

To facilitate this study I have had a small apparatus made, consisting of an exploratory tube formed of an interior metallic framework, to which an indiarubber finger-stall is attached. This exploratory tube, which is otherwise hermetically sealed, communicates by means of an indiarubber tube with a very sensitive Marey drum. The sensitiveness of the exploratory tube may vary with the thickness and tension of the rubber used. This tube is applied to the palmar face of a finger, whilst a larger tube serves to register the pulsations in the plantar face of the great toe. It is also possible to get good records by means of a tube with two sensitive surfaces placed between the lateral faces of two fingers. The circumstance that by this last method the pulsations of the digital arteries are registered does not constitute a source of error, for these small arteries of muscular type are subject to the same influences which operate on the vaso-motors. The exploratory tube is held in place by two metal plates joined by four tension screws, which allow of its being pressed more or less closely against the surface of the fingers. This affords an easy and rapid method of regulation and produces good records.

The precautions usually taken when registering vaso-motor modifications must, of course, not be neglected. The subject must be at rest in a well-warmed room. It is also desirable to have the hands or feet, whichever are to be explored, in surroundings at a constant temperature. For this purpose I have used one of the electrically warmed pieces of textile fabric sold under the name of electric cataplasms.

With two apparatus of this kind it is possible to register the fingers of both hands at the same time. This device has provided me with diagrams of great amplitude showing very clearly variations caused by different influences originating at the periphery or at the centre. But like the other appliances it falls short of invariably giving satisfactory results, since numerous subjects produce graphs of very little use in spite of the very best appliances and preparations, either because they are under the influence of cold, or emotions, or for some other appreciable cause.

The registration of vaso-motor reactions in man always remains a delicate affair, in spite of the use of newly made thin rubber membranes and of the very sensitive Marey drums.[4]

3. *Study of Tremor.* (Figs. 1 and 2.)

A fairly large number of soldiers present symptoms of tremor, due to wounds of the nervous system, or concussion, or emotion, or other clearly determined cause. It was of interest to register and try to differentiate these tremors. For this purpose I used various devices. One of the simplest is formed of a very sensitive drum, which has at its centre a small metal plate to which a long metal rod is screwed. This rod is placed in or on the subject's hand, which may take up several positions successively, pronation, supination, or any intermediary position. The drum is connected with a registering drum.

[4] Appareil pour l'inscription des modifications vaso-motrices chez l'homme, by Jean Camus, Société de biologie de Paris, June 3rd, 1916, vol. lxxix., p. 525.

Another device is formed of drums between which one can introduce the hand or an arrangement like the spokes of a wheel. This apparatus gives horizontal, vertical, and antero-posterior tremors, which can be registered separately or conjointly by uniting the drums in various combinations by means of tubes with several ramifications.

In a third device the five drums, instead of being fixed, are mobile and attached to a series of hollow rigid tubes, held like a bundle in the hand of the subject. Rubber tubes leading to the registering drums start from these hollow tubes. During the tremor the sensitive membranes of the five drums (two vertical, one superior and one inferior; two horizontal, one to right and one to left; one as far antero-posterior as possible) strike against small rigid rods fixed in proximity to them.

These devices insure the correct registration of the various forms of tremor, even the slightest, such as the normal tremor which exists in everyone.[5]

A very large number of good graphs taken with the first apparatus described above have been published in the important thesis by Dr. Binet, which comprises a detailed study of the various modalities of tremor.[6]

4. *Device for the Selection of Aviation Candidates.*

My laboratory established in the Grand Palais has allowed me to study the question of the selection of aviation candidates. In 1915 Dr. Marchoux, at that time chief medical officer of the Fortress of Paris, had asked me to investigate the aptitude of men wishing to become pilots by means of the physiological methods employed by me at the Grand Palais. The researches undertaken were pursued and brought to a very high pitch of perfection with the collaboration of Dr. Nepper, who unfortunately died in the course of the last influenza epidemic. We gave a first description of our method in the *Paris Médical*, March 18th, 1916. This method comprises two parts: 1. Measurement of psychomotor reactions with the aid of d'Arsonval's chronometer. 2. Registration, by the graphic method, of respiration, the cardiac rhythm, and the vaso-motor variations of the tremor considered as capable of revealing the emotivity of the subjects under investigation.

I was guided by the idea that it was useful not only to find out the rapidity of the psychomotor reactions (visual, auditory, tactile), but that it was also important to know the value and duration of the emotivity reactions called forth by a series of tests. Both parts seemed necessary, and I considered that they must be complementary to each other.[7]

As a matter of fact, a subject who has rapid psychomotor reactions may possess excessive emotivity, which he is unable to master, and is in consequence a bad aviator. Another may have very slow psychomotor reactions, too slow for him to be a good aviator.

Either alone or helped by several medical men (MM. Arrous, Binet, Turlais, Vallée, &c.), my collaborator carried out a huge number of examinations of aviation candidates. In his practice he soon gave up the registration of emotivity reactions, retaining only the measurement of psychomotor reactions, to which we had added, on the advice of our master, Ch. Richet, the idea of mean deviation. I cannot say whether this simplified method is enough, but for the reasons given above I do not think so, since to my mind the two parts of the device must be complementary.

From the facts which I was able to verify in collaboration with Dr. Nepper, and from those far more numerous ones verified by himself alone, it follows that in extreme cases the method described gives satisfactory results which are entirely in its favour. The very good aviators, the well-known "Aces," gave excellent psychomotor reactions and either feeble or completely controlled emotivity reactions. Inversely, persons who are ill or wounded in the head, and particularly cases where trephining has been carried out, who should theoretically be little adapted for flying, have provided bad psychomotor reactions and excessive and prolonged emotivity reactions.

The method described is doubtlessly susceptible of improvement, and may, perhaps, also be open to criticism—for example, it should be easy to add to our original method some more or less complicated tests of judgment, by provoking, or omitting to provoke, emotions during these tests. On the other hand, a critical study might be undertaken by using the method for the examination of a large number of pilots, who may be either very good, or good, or still mediocre pupils, at the beginning, in the middle, and at the end of their pupillary stage. Attention might equally be given to the degree of perfectibility of the subjects.

The war has given aviation a surprising impulse, but it is only at its beginning, and the future of aerial locomotion appears to every eye to be nearly without limits. It is very desirable that the recruiting of pilots should be treated with the utmost gravity and that comparative studies of selective methods should be undertaken in all countries.

THE LAWS OF TREMOR.

BY DR. LÉON BINET,

INTERNE DES HÔPITAUX, PARIS.

BY using a sensitive appliance, Marey's graphic method allows us to study and analyse tremor and to investigate the laws which govern this phenomenon. With this aim in view we have availed ourselves of the apparatus devised by our master, Jean Camus,[1] consisting of a very sensitive drum bearing at its centre a small plate, to which a metal rod is screwed. This metal rod is the exploring organ, which is applied to the region to be studied and attached to it by a string. This first drum (called the explorer) is connected with a second drum (called the receiver), the needle of which moves over the surface of a cylinder, where it also registers the time in seconds. Records thus obtained[2] show that it is necessary to distinguish physiological tremor from pathological tremor. It is the former that we wish to dwell upon now.

A. *Physiological Tremor.*

All normal subjects reveal a tremor which disappears only when the part of the limb under investigation is in a state of complete rest, totally relaxed, on a resisting plane. This tremor is general, and consists of nine oscillations per second in the case of the tongue, eight to nine in the upper limb, and five in the lower limb. These oscillations vary in amplitude, and the examina-

tion of the records allows us to distinguish two types: an unstable type (irregular oscillations) and a periodical type (recalling the periodic Cheyne-Stokes respiration). Physiological tremor presents variations the study of which permits of the description of the laws of tremor.

B. *The Laws of Tremor.*

1. *Tremor calls forth tremor.*—Let us take the record of the normal tremor of a subject by means of the registering appliance described above; then let us order him to tremble voluntarily. If the patient is finally instructed to stop his voluntary tremor, the record shows that it continues to imitate the intentional tremor and is entirely different from the original record.

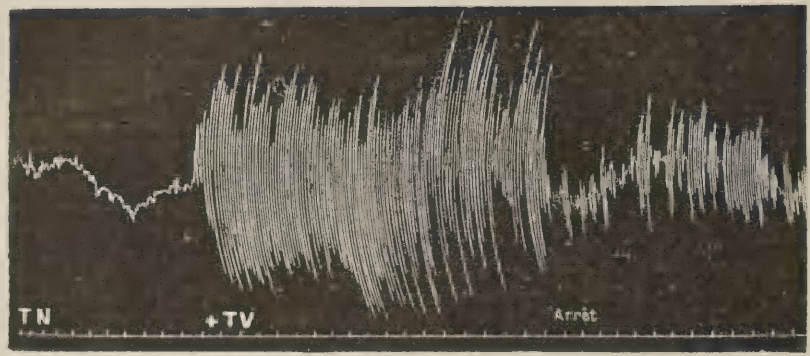

Fig. A.—Tremor, at first normal, then voluntary, and finally arrest of the voluntary tremor. (Tremor calls forth tremor.)

2. *Tremor increases as the result of muscular contraction and becomes exaggerated under the influence of work.*—Dynamic work increases tremor, first in that part of the body which has worked (*law of unilaterality*), then in the opposite member (*law of symmetry*), and finally becomes general (*law of generalisation*). Static work (maintaining a weight in a raised position) exaggerates the tremor, the increase of which is a function of the resistance of the member under observation, so that we have in it a proof (proof of tremor) which allows us to compare clinically the functional value of an unsound member by comparison with that of a sound member (investigation of cases of myopathy[3]), wounded limbs, encephalic wounds with peripheral motor disturbances.[4] Intense and prolonged mental work exaggerates the oscillations.

We see, then, that work in any form increases the tremor, and experience shows that tremor reacts on the work, for, owing to the fact that a subject trembles, voluntary contractions become less rapid and less frequent. We have there an interaction of evil processes which affects injuriously the proper output of the human motor.

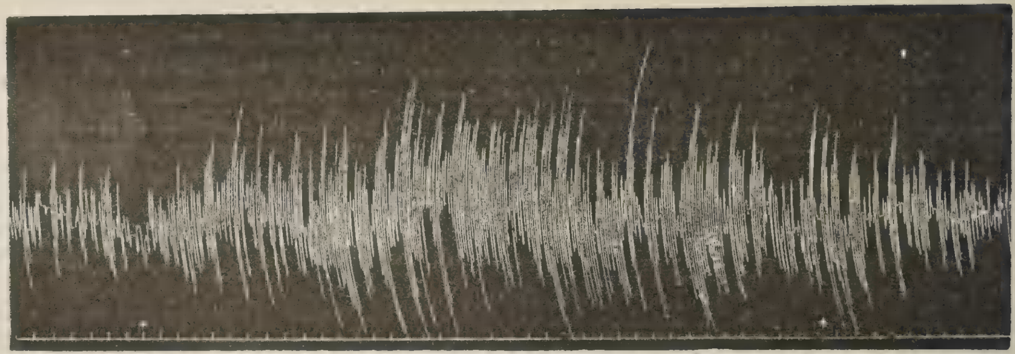

Fig. B.—Influence of mental work on tremor. (The subject under examination works mentally between the two crosses.)

3. *Tremor increases in consequence of emotion.*—Whilst the tremor record of a subject is being taken, fire a blank charge in a revolver and examine the tracing made. After the lapse of several seconds (from 4 to 20) an increase in the tremor will be noted. This increase is progressive, as if an intense tremor had been unmoored and was destined to be entirely let loose. The intensity of this tremor is a function of the "coefficient of emotivity," of the "threshold of emotional excitation," of the subject under examination.

4. *Tremor may be modified by respiration.*—Charles Richet's beautiful experiments[5] on dogs anæsthetised by chloroform, cooled to 34°C., demonstrate the existence of a shiver, which is at first limited entirely to inspiration and later on is continuous, but exaggerated at the time of inspiration. A similar fact may be observed—exceptionally, it is true—in the case of human beings. One patient under examination showed a clear exaggeration of tremor whenever he made a forced inspiration.

5. *Tremor is exaggerated under the influence of cold.*—It is a matter of common observation that we tremble when we are cold, and this thermic shiver in the dog has been studied at length by Charles Richet. The human being presents a similar thermic shiver caused by the impression of cold, having a cutaneous starting-point and a muscular end-point. The trembling may be general or partial, but it has an obvious predilection for the masticatory muscles, due to some peculiar sensitiveness of the mastication centre.

6. *Tremor is modified by peripheral impressions.*—Painful impressions received on the periphery increase tremor very noticeably. It is well known that in the case of animals Claude Bernard demonstrated a general tremor on galvanising the central end of a cerebro-spinal nerve. In human beings the painful exploration of a wound or the moving of an affected articulation sets up manifest tremor. On the other hand, certain actions carried out on the periphery have a diametrically opposite effect. Thus ocular compression brings about the arrest of a rigor (oculo-motor reflex[6]), and one can notice the rigor of infectious fever and the tremor of neuropaths lessen in a marked way under the influence of pressure on the eyes.

THE LANCET.

LONDON: SATURDAY, JANUARY 31, 1920.

The Voluntary Hospital System.

A STORY is told of a draper who, in the olden ys before the war, sold pins and bric-à-brac low cost price, but made a profit by selling great quantity. That is the position of the luntary hospital to-day; the number of its tients steadily increases, it loses a little on each them, and the treasurer has no luxury department to blind him, by its large profits, to the t that little losses indefinitely multiplied ke adverse balance-sheets and ultimately large erdrafts. The draper could rejoice in what ks like suicide, because, while bankruptcy was oided, the sale of luxury articles would save n. Between 1913 and 1918 the occupied beds 109 London hospitals increased from 9766 to 566, and the ordinary expenditure, after allow- for reimbursement on account of naval d military patients, rose from 1143 to 1611 ousands of pounds. In regard to provincial spitals, a casual dip into our news columns this ek will show that the Leeds Infirmary has an nual deficit, in round numbers, of £26,000, and bank overdraft of £39,000 which would have been ich greater but for a generous donor of £50,000. the Norfolk and Norwich Hospital the cost per patient has risen from £4 13*s*. in 1913 to £8 13*s*. 6*d*. 1918. It is a topsy-turvy sort of business, in ich the larger the turnover the greater is the s. And unless something is done, bankruptcy is t far distant.

At this point Sir ARTHUR STANLEY steps in with optimism which nothing can daunt, and which tainly found its justification in the experiences the Red Cross during the war. Given the proper chinery for collecting money and convincing idence that the money is put to a good use, he is re that the public will voluntarily find the oney. Not the same class as found it in 1910, then it was the bourgeois with enough and to are from moderate salaries, and they have now as ich as they can do to keep afloat at all. But less an 9 per cent. of the population, according to Sir NRY BURDETT, then contributed to hospitals at , and Sir ARTHUR STANLEY proposes to tap the rking-class population by voluntary levy of so ny pennies per week. Taking 300 hospitals of) beds each, that is 45,000 beds, at an annual cost £150 a bed, it is not difficult to see that the million pounds required each year, of which not ore than a third is covered by endowment, would amply raised from a population of 40 millions. ch of whom contributed 1*d*. a week. And in the wcastle area a suggestion to the miners that their present contribution of 1*d*. a week should be doubled has met with a ready response. The Red Cross, as will be seen on p. 278, has put its unrivalled collecting machinery, which has never broken down although now arrested for overhauling, at the disposal of the voluntary hospitals, and has offered the whole-time services of Sir NAPIER BURNETT, of auxiliary hospital fame, to set the machine going. He may be able to reassure the private donor. Certain spinning towns, which scarcely make a secret of their opulence, would finance their own voluntary hospitals generously but for uncertainty as to State control. How these would-be givers can misinterpret Dr. ADDISON'S repeated assurance it is difficult to understand; the Ministry of Health has more sense than to interfere with institutions efficiently financed and run. It is believed that it will refuse to allow municipal bodies to borrow money for hospitals in places where private enterprise is active and enlightened.

One condition, and one only, is attached by the Red Cross to its offer of help, and it is a condition which the British Hospitals' Association is as keen to ensure as the Red Cross is to impose. Efficiency and economy must be the watchword of hospital administration. There is no complaint—there never has been—of the devotion of the voluntary officers, medical and otherwise, attached to the particular hospitals, but there has been a lamentable lack of coöperation between hospital and hospital, and nowhere a proper county scheme. Sir NAPIER BURNETT, who recently undertook a general hospital survey in the north-eastern area, which covers 2 million acres and 2½ million people, found a hospital (general and special) bed-rate of ¾ per 1000 of population, with some 3000 names on the waiting list. The area provides precisely the same number of beds for infectious diseases as for all other diseases and accidents. There are double the number of beds in Poor-law infirmaries, of which only about one-half are occupied. A scheme is afoot for collecting £100,000 for a war memorial hospital to be erected a stone's-throw from a spot where lie empty 200 infirmary beds, which could readily be separated from the workhouse. Verily, all is not well with coördination. Sir NAPIER BURNETT has wise things to say concerning remedies, especially in the direction of a great development of the convalescent hospital, in which the annual bed-cost should be less than one-half of that in the general hospital. We may hope much from a hospital survey of the whole country carried out with sympathy and imagination. Mr. BASIL MAYHEW'S plea for a strong committee to be set up in each county, to adopt a definite hospital scheme under the guidance of a single central coördinating body, has much to commend it. In the meantime, with the help of the Red Cross the voluntary hospital system may be able to carry on through the lean years of reconstruction. We hope it will. But it will require a strong pull with all the forces balanced by intelligent administration.

The Increase of Criminal Abortion.

IT is to be hoped that the sentences passed by Mr. Justice DARLING upon three criminals at the Central Criminal Court, and the terms in which he addressed the prisoners, will have been closely studied by all persons engaged in the trade of the abortionist, and also by the police authorities, who should be encouraged in every effort to stamp out that trade. A man named GARDNER pleaded guilty to using an instrument to procure the miscarriage of a woman named SMEDLEY, and two other men—EASSON and TITMAN—pleaded guilty to aiding and abetting him. In another case GARDNER and EASSON were found guilty of the manslaughter of a woman, GARDNER by performing an illegal operation, and EASSON by aiding and abetting him. The men were sentenced, GARDNER to ten years' penal servitude, being described by his lordship as a "professional abortionist," EASSON to penal servitude for two concurrent periods of five years, and TITMAN to 18 months' imprisonment with hard labour.

Mr. Justice DARLING, dealing with the general aspects of the serious crime of abortion, in passing sentence, said: "There are those who write about what they call 'race-suicide.' The term does not matter. But a country which permits its population to be dealt with in this way is bound to decay. Those who have as many enemies as the British Empire must for their own safety have plenty of children to meet those enemies in the gate. We have many gates to defend; therefore it is that the law for that and other reasons makes these practices penal and awards a heavy punishment for them." In sentencing GARDNER his lordship told him that he was fortunate in not having been convicted of murder. He thought it high time that a man who had killed a woman, as GARDNER had done, and had practised abortion over and over again, should be convicted of murder and hanged, adding that if he had been so convicted not a word would have been said by the court to save him from the gallows. His lordship dwelt further upon the proof, supplied by the case, of the increase of the practice of abortion during the circumstances produced by the war, the public conscience being dead with regard to it. He referred to evidence given by the prisoner TITMAN, a former clerk in the Army Pay Office at Winchester, that pregnancy and how to procure abortion were common topics of conversation among the young men and women working there. Of EASSON (described as a masseur) Mr. Justice DARLING said that he was employed in a shop in Villiers-street, stated to belong to a man named NATHAN, who seldom went there himself. The business carried on was mainly in "regulators," medicines, pills, and appliances the object of which was obvious. Of the pills his lordship said that it was believed by those who bought them that they were capable of procuring miscarriage. They were sold at 10s. a box, and if they failed in their purpose were labelled "double strength," and sold at £1 a box. Of TITMAN his lordship said that in spite of his youth he was thoroughly debauched and immoral. Certainly in three or four cases he had been the means of introducing young women to the nefarious practices carried on, and EASSON had said that some of them came to the shop in their various uniforms.

If the trial, which Mr. Justice DARLING has thus brought to an issue beneficial to the public, is to bear any fruit, its result should be the closing o other places of business of the kind described They are perhaps not so conspicuous as they were a few years ago, but the police must be aware of many of them. The trade in alleged abortifacients cannot be carried on without certain amount of advertisement, if it is to be on a profitable scale, and the window of the shop where "regulators" are sold i generally filled with articles and papers clearly indicating the class of customer for which it caters But though anyone can see what is going on prosecutions may be hard to start. Women wh desire to avoid the burden of maternity are no often willing to be witnesses to criminal practice in which they have been participators, and even those most antagonistic to the employment of th *agent provocateur* may regard her or him a indispensable in the circumstances. The greed o the trader of this class upon public credulity wil almost certainly cause him to supply, on mer application, documentary evidence such as wil admit no denial of his guilt. Death from procurin abortion probably does not occur so frequently a formerly in proportion to the number of illega operations conducted, for the importance of asepti conditions and the means of obtaining them ar more widely known than they were; but thi increases the necessity of detecting the abortionist, even though he has to be, as some person would say, entrapped.

The Last Report (Medical Supplement) of the Local Government Board.

THE Annual Report of the Local Governmen Board for 1918–19 is accompanied by the supplementary report of the Medical Department of th late Board for the period. The document is submitted by Sir GEORGE NEWMAN, the Chief Medica Officer of the Ministry of Health, who was appointe in 1919 as Principal Medical Officer of the Board i succession to Sir ARTHUR NEWSHOLME; the medica supplement is the last of a famous series whic began 64 years ago under the Joint Board of Healt which had been instituted in 1848. The series wa continued under the Medical Department of th Privy Council, and, finally, from 1871 until this las document, was issued by the Local Governmen Board. In a letter to Dr. CHRISTOPHER ADDISO he first Minister of Health, Sir GEORGE NEWMAN ntroduces the Report by recalling the work of his predecessors in office, calling special attention to he broad principles of State medicine initiated by Sir JOHN SIMON, Medical Officer to the Privy Council from 1855 to 1876, and alike the father of scientific preventive medicine in this country and the pioneer of similar activities throughout the civilised world. Recognising that the publication of this Report closes an epoch, Sir GEORGE NEWMAN calls attention to the fact that the Local Government Board from 1871 to 1919 gave to the nation, not only in this series, but in the actual work behind the reports, a method consisting of "a combination of scientific work and common-sense administration both associated with a wide and comprehensive vision." That is a perfectly just claim, and leaves no need for addition.

The Report itself, which has been prepared by Dr. G. S. BUCHANAN and Dr. R. J. REECE, respectively First and Second Medical Officers to the late Local Government Board, follows generally the lines of the reports emanating from previous heads of the department; but in view of the termination of the Local Government Board as a Department of State, upon the creation of the Ministry of Health, no such complete survey has been given, as in some of the earlier documents was thought necessary. The present Report is mainly concerned with notes and records regarding certain infectious diseases, and with a chronicle of the work done during the last stages of the war for the prevention of tuberculosis, the control of venereal disease, the administration of port sanitation, the inspection of food, and, especially, the care of children and nursing mothers. These are all matters in which it is important to maintain continuity of record, and the information compiled under the various headings is valuable in its authoritative and concentrated form. The history of the great epidemic of influenza, contributed by Dr. T. CARNWATH, and representing the views of the epidemiologists of the bureau, is a thoroughly useful contribution. The difficulty of preventing the spread of a highly infectious and rapidly developing disorder is indicated by the circumstances detailed. The disease first attracted the attention of local authorities in England in June, 1918, but this appears to have been later than the date at which cases occurred in Spain, in Japan, in the United States, and in certain of our own naval and military bases; so it was surmised that in many places the first English cases occurred in association with soldiers or sailors convalescing or home on leave. By the middle of July what had now become an English pandemic was at the top of its severity, and Dr. CARNWATH illustrates the incidence and its results by curves which display the behaviour of influenza in different centres of population. These curves show well the autumn fall and the second epidemic at the end of the year 1918, the crest of this second wave being reached on Nov. 9th, when over 7000 deaths from influenza were registered in "the 96 great towns." The contradictory features of the disease, as it manifested itself in various and separated localities and in age and sex groups, bring Dr. CARNWATH to the hypothesis that there are several strains of influenza virus and that these vary in virulence and antigenic potency; but the hypothesis is only put forward as one that most nearly reconciles conflicting evidence, and the essential message emerges that influenza is a crying subject for organised medical research.

Dr. BUCHANAN is responsible for the section on epidemic diseases in this country associated especially with war conditions—namely, malaria, dysentery, and such louse-borne diseases as typhus and trench fever. A great deal of the general information under all three headings has been published in THE LANCET in the form of reviews of reports issued by the Local Government Board for the information of the public, and the section shows how alert the authorities were to prevent conditions which were inseparable from those of war spreading from our sailors and soldiers to the civilian population. With regard to louse-borne diseases, so good a system of cleansing was carried out that infestation by vermin has been of the rarest occurrence in the homes of the returning army—among sailors, of course, no such risk existed. There has been no material increase in prevalence of lousiness among our general population. The possibility of bacillary dysentery must still be kept in mind; while the occurrence of any sudden severe gastro-enteric attack should be noted, the amount of danger attaching to amœbic infection in this country still needs determination. The question of the spread of malaria remains under close observation, and practitioners should remember that at the Ministry of Health all help will be given. If doubt arises as to any case or group of cases, it is important that the specialised assistance of the department should be sought.

◆

The Limit of Standardisation.

A RECENT issue of the *Journal of the American Medical Association* contains a plea for the standardisation of laboratory tests. It is pointed out how easily confusion may arise in the interpretation of the results obtained with complicated biological and biochemical reactions, especially when numerous modifications of any one test are used in daily practice. Figures presented by different observers, and presumably purporting to represent the same thing, may not be comparable unless the same methods have been used or, if the methods vary, unless an exact comparison has previously been made. This applies, perhaps, with more force to the Wassermann reaction than to any other laboratory diagnostic method, though the same may be said of most of the difficult modern tests. The hard position has long been recognised, and attempts have been made to obtain agreement as to what shall constitute standard conditions. In this respect we are perhaps somewhat ahead of our American colleagues. Professor DREYER'S attempt to put the agglutination reaction on a quantitative basis is an example of the kind of work which, we take it, the American journal would like to see done. Perhaps the admirable series of reports now being issued by the Medical Research Committee on the "Standardisation of Pathological Methods" will lead to an improvement in the general reliability of laboratory work. The reports already issued by the Committee include one on the method of standardising bacteriological media—a matter obviously of first-rate importance—one on the laboratory diagnosis of gonococcal infections and the detection of spirochætes, and two on the Wassermann reaction and its diagnostic value. They are written by experts in each subject and contain the detailed information which even the largest text-books omit for want of space. Incidentally, chemical manufacturers have an unrivalled opportunity of supplementing such work—and of reaping large profits—by supplying chemicals of guaranteed purity.

All this work is to the good, but it should not be forgotten how near it approaches to dangerous ground. Beyond certain limits we trench upon a question of fundamental importance in science, that of the foundation of authority. We may unify the simpler methods, which are based on precise knowledge, and no harm follows. Indeed, the general tendency is towards simplification as our knowledge of principles grows. But attempts to bring about complete uniformity in the technique of biological reactions, which are yet only partially understood, would hinder rather than help progress. Standardisation must have behind it work which has been often verified and is generally accepted; and original work must not be limited by any suggested rule. It is still beyond the wit of man, or of committees, to devise any scheme which shall absolve us from the necessity for critical reading and study. So in the end each man must make his own choice out of the multiplicity of methods open to him.

THE Mary Putnam Jacobi Fellowship of $800 (about £200) is offered by the Women's Medical Association of New York City for post-graduate study in any country to any woman physician for work in any medical science. For full particulars apply Dr. C. M. Murrell, 86, Porchester-terrace, London, W. 2.

UNIVERSITY OF CARDIFF.—Sir Edward Sharpey Schafer visited Cardiff recently and delivered an interesting address in the large lecture theatre of the new physiological department. He discussed, very appropriately, the construction of laboratories and hospitals of medical schools, and pointed out the inexpediency and folly of placing such buildings in great cities on confined and expensive sites with no room to expand, except at prohibitive cost. He advocated and illustrated the American method of obtaining, while land is reasonably cheap, a campus far beyond all immediate requirements. He pointed out that local authorities are longer lived than the men who at any time constitute them, and that they must plan ahead for 200 years or so, otherwise their reputations will suffer at the hands of future generations, who will have to shoulder their mistakes, instead of inheriting the fruits of their foresight. The address was listened to with interest by a receptive and representative audience.

Annotations.

"Ne quid nimis."

PREPARATIONS FOR AN INFLUENZA EPIDEMIC.

THE Ministry of Health has issued an intimation to the public of the possible recrudescence of influenza in this country, resuming a Memorandum issued in December last to Local Authorities. The facts reaching the Ministry from sporadic sources in England and Wales, as well as the prevalence of the disease in Japan and India in the east, and in the United States in the west—to say nothing of reports from Central Europe—make it probable that an epidemic may again develop in this country. Readers of THE LANCET will recall that early in November last Dr. John Brownlee, the Director of Statistics at the Medical Research Committee, suggested that an epidemic could be anticipated, by a right reading of the figures, somewhere about the end of January. The prediction was made tentatively, the capricious behaviour of epidemics being noted, and Dr. Brownlee tied himself down to dates in no close manner; but he gave a warning which should not have been neglected, especially in view of the Memorandum of the Ministry of Health.

The advice now given by the Ministry to the public, to the Local Authorities, and to those who will have charge of the sick will be found summarised below. It is in essentials an insistence upon counsel that has been previously issued; therefore we may trust that the warning is being addressed to enlightened hearers, who may have already considered in advance the procedure which should be adopted if the day of trial arrived. Under the heading of prophylaxis nothing very definite is said by the Ministry upon the value of inoculation, nor can medical science expect a pronouncement. We are dealing with a disease whose actual causal agent, or combination of agencies, is unknown, though considerable evidence exists, emerging from the 1918 epidemic, that inoculation has done good work in certain groups of cases. It is obvious that in this direction wide as well as concentrated research should be undertaken. The problem is a difficult one, and to stop out many of the sources of error which are present will require great industry and logical powers. Now is the time for their application, with past facts recorded recently and new ones arriving.

Although the latest official returns do not indicate any ominous or sudden increase of deaths attributable to either influenza or pneumonia of an infectious type, the Ministry of Health, drawing special and public attention to its recent Memorandum, reminds us of the infectious nature of incipient influenza. The following advice, not for the first time, is given to the public, the patients, and those who have charge of them:—

Prophylaxis.

Infection may be guarded against by:—

Healthy and regular habits and avoidance of fatigue, chill, alcoholic excess, crowded meetings, hot rooms, and unnecessary travelling. There should be good ventilation in working and sleeping rooms, and warm clothing should be worn. Gargling is recommended from a tumbler of warm water, to which has been added enough permanganate of potash to give the liquid a pink colour. A vaccine against influenza has been prepared by the Ministry of Health and is available for general use, following the War Office procedure.

It is issued to medical officers of health for distribution free of charge among doctors, and any person who wishes to be vaccinated should apply to his own practitioner. To obtain its value the vaccine should be used *before* the epidemic occurs. The procedure is not necessarily protective, but it may lessen the risk of the dangerous ensuing complications.

Advice to Patients and Nurses.

In the event of an attack of influenza the patient is advised to adopt the following measures to secure rapid recovery without complications :—

At the first feeling of illness, or immediately on a rise of temperature, the patient should leave his work, go home, and go to bed ; he should keep warm and should send for the doctor.

On convalescence the patient should avoid meeting-places and places of entertainment for at least one week after his temperature has become normal. Recovery should be fully established before return to work.

Persons nursing influenza patients are instructed that the sick should occupy a screened-off bed or a separate room until the temperature is normal. Though warmth should be secured, ventilation should be free. Inhalation of the patient's breath or contamination from sneezing or coughing should be avoided, and the hands washed after contact.

Advice to Local Authorities.

Local Authorities are urged to consider *in advance of an epidemic* the advice issued in the Memorandum, stress being laid upon the following :—

The immediate appointment of an emergency committee.

Scheme for coöperation with medical practitioners and voluntary health workers.

Provision of nursing.

Subdividing the district for anti-influenza work.

Provision of home helps.

The utilisation of the local authority's staff.

Emergency hospital provision.

The prevention or mitigation of overcrowding, especially in public vehicles.

Workers who are obviously ill should be sent or taken home at once.

The vaccine, prepared by the Royal Army Medical College and supplied by the Government Lymph Establishment (Colindale-avenue, The Hyde, London, N.W. 9), is issued gratuitously to medical officers of health and through them to medical practitioners who desire to use it. They are requested to keep careful notes in respect of each person inoculated, of the name, address, sanitary district, age, sex, dates of previous attacks of influenza, date of present inoculation, and subsequent history, so that trustworthy figures may be obtained as to the results of inoculation.

Action in Advance.

The Ministry of Health announced on Thursday morning that during the months in which the country has been free from epidemic influenza the investigations into the circumstances and conditions which lead to a spread of the disease have been conducted, so that, should another epidemic occur within the next few weeks, it will find the country better equipped in respect both of theory and practice to meet the attack. They state :—

The Ministry keep a constant watch on the occurrence of influenza at home and abroad and have put themselves in a position to observe closely the progress of any epidemic wherever it may occur. Information is derived from returns as to epidemics obtained from Consular Agents and from other official sources all over the world. As regards the prevalence of the disease at home, information comes from the weekly returns of influenza mortality in the 96 great towns issued by the Registrar-General, and from returns of cases of acute influenzal-pneumonia, the notification of which is now obligatory on all medical practitioners in England and Wales. Returns of cases of influenza are also furnished voluntarily every week by a number of schools, institutions, and representative industrial firms throughout the country. All data on the subject, statistical as well as scientific, come before an Influenza Committee, which is a Medical Standing Committee of the Ministry of Health, holding frequent meetings, and on which sit representatives of the various Medical Departments in Whitehall.

A vaccine against influenza has been prepared by the Ministry and is now being issued on demand to medical officers of health for distribution, free of charge, among medical practitioners within their districts. It is not guaranteed that this vaccine will in all cases necessarily protect from attack, but the experience of the military authorities, and of the eminent bacteriologists consulted by the Ministry, justifies the belief that the use of this vaccine will, in many cases, actually protect from attack, and should such attack occur the person who has been vaccinated beforehand will be less exposed to the risk of complications. It should be added that steps have been taken to protect the country as far as may be from the introduction of influenza through the ports.

The further activity of the Ministry may be conveniently grouped under the headings of education and research. The knowledge and experience accumulated during recent epidemics have been collected and issued to local authorities at various times in the last 12 months. Within the last few days a leaflet has been issued for popular use (see above), and setting out the best measures of guarding against infection, together with advice to patients as to the best known means of securing a speedy return of convalescence and the avoidance of those complications which constitute the special danger of influenza.

Meanwhile, much active research continues by the medical officers of the Ministry into the causes of epidemics of influenza. Special inquiry is being made in selected districts into such questions as immunity, the effects of overcrowding, incidence according to age, and so on. The medical officers who are conducting these investigations are in close touch with the work which is being carried on by other investigators, and are making their inquiries in collaboration with the Medical Research Committee.

THE STRUGGLE FOR EXISTENCE AMONG LOCAL AUTHORITIES.

DURING the past few weeks portions of the country have become the scene of an interesting and significant struggle between local authorities, some seeking to expand, and others to maintain, their civic boundaries. The storm-centre has been in Yorkshire, where some half-dozen of the larger cities and boroughs are severally seeking powers from Parliament to engulf adjoining districts—already in some instances flourishing communities—and by the same act to deprive the County Council of the West Riding of an important portion of its administrative area. While this form of warfare is by no means a new phenomenon, the period of comparative quietude produced by concentration on a greater war, followed as it now is by this sudden fury of desire for a more conspicuous place in the sun, has brought into unexpected relief the issues underlying the movement. Let it be granted that the contest brings to light a number of unedifying traits ; that its aspect of self-aggrandisement, or so-called civic pride, leaps to the eye ; that it is selfish in its lack of consideration for the needs and desires of the smaller authorities involved, and materialistic in its motto: "Let us swallow, lest another swallow first." Nevertheless, beneath all this there appears to be the motive of grappling with a most vital question in English local administration—the definition of the areas most suited to the various functions of local government. This can be appreciated by anyone who attempts to analyse for himself the public health aspects of the position. How would an unprejudiced medical officer of health propose to give evidence as to whether or not, from the standpoint of the public health, a particular city should extend its boundaries and thereby absorb perhaps an urban, perhaps a rural, district previously governed by its own electorate and administered, aided, or supervised as to some of its public health activities —e.g., education, midwifery, treatment of tuberculosis and of venereal disease, maternity and child welfare, &c.—by the county council? The decision becomes an embarrassing one, and is still more so when considered in general terms without reference to particular areas. Take two of the main communal functions—the provision of water and the disposal of sewage. Certainly the absorption of the smaller into the larger district is, on the whole, likely to lead to a larger and better water-supply for both. But is this necessarily the true ideal, or would it not rather be better that the duty of supplying water both to the city and to the district should be delegated to a still larger authority— perhaps a county council or a group of county councils, with control of an entire watershed, and with power to distribute the supply not only to industrial centres but also to the more remote rural districts? In respect of sewage disposal, again, the larger the scheme the more likely it is to be efficient, and the collection, treatment, and disposal of sewage is likely to be better done by a large city than by a small district. But what of the large towns in which the pail-closet and the midden are still to be found? Should these be encouraged to further civic ventures before they have met their existing responsibilities in this respect? Again, what type of local authority best retains that personal touch and interest on the part of the administrative officer so essential to the efficiency of work such as that of maternity and child welfare, and of the control of tuberculosis and venereal disease? Is it the county, the large city, or the borough with a population of 50,000 to 100,000?

These are but a few of the problems which spring at once out of cursory inspection of the position. A searching official investigation into the whole matter is needed, to include a scrutiny of the relative capacity of the various types of existing authorities, and of such new authorities as may be suggested in substitution. We commend the matter to the Minister of Health for serious consideration. It is true that the department has a vast mass of work to do, but in the course of that work it is acquiring cognate information.

MENTAL TESTS.

AT a recent meeting of the Educational Section of the British Psychological Society Dr. P. B. Ballard gave an interesting account of the development of measurement as applied to the data of psychology. He showed how the first attempts had passed from the physical through the psychophysical to the purely psychological side in modern times. The value of properly standardised mental tests of intelligence and of ability in school subjects is fast becoming recognised. Indeed, there is a tendency to exaggerate their value and to suppose that mental defects can be diagnosed merely from the data afforded by such tests. They are valuable enough instruments in the hands of the expert, but untrustworthy servants when used by the ignorant and untrained. Of equal promise are the special tests now being devised to ascertain the relative fitness of different individuals for different occupations in life. No one is so suited to take up the application of these various tests as the medical man trained in modern psychology. The opportunities for their use are daily increasing. As Professor John Adams observed in his recent address to the Association of University Women Teachers, certain pioneer employers in this country are already using mental tests in order to select those best fitted for particular types of work. The Industrial Fatigue Research Board and the proposed National Institute of Psychology and Physiology Applied to Industry and Commerce will also doubtless be in need of suitable investigators in relation to vocational selection and guidance.

TWENTY-FOUR YEARS OF RADIOLOGY.

1. The first radiograph from human hand, made in London, Jan. 13th, 1896 (20 minutes' exposure).

2. Human hand taken December, 1919 (1/100 second exposure).

These are the first two exhibits at the Royal Photographic Society's Exhibition of X ray prints. They give the key to the immense progress which has occurred in the 24 years since Professor Röntgen's far-reaching discovery was flashed throughout the length and width of an astonished world. In "No. 1" the distal phalanges are barely visible; there is no sign of the metacarpal bones in spite of the 20 minutes' exposure. "No. 2" shows a great wealth of detail of bone structure, and a good deal of differentiation of the soft parts—all achieved with a "flash" exposure. The crude instrument of 1895 has been replaced, step by step, by apparatus of ever-increasing power and efficiency. This improvement in the technique of radiography is still going on; the recent invention of the Coolidge tube is a notable instance; none can say when or where it will end. Side by side with the technical advance has gone a corresponding increase in the range of application of the X rays to purposes of diagnosis and treatment, while two dozen years of experience, the world over, have established the interpretation of the X ray pictures, and given confidence to the radiologists in arriving at their diagnoses.

Perhaps the most predominant impression gained by a visit to the exhibition is the great extension of the uses of the X rays for industrial purposes. There are radiograms of golf balls, of shells and fuses, of metallic rods, tubes, and plates, showing faults, defective welding, and so forth. The radiographs of patients show a very wide range of subjects: metallic foreign bodies, fractures—war injuries figuring largely in both categories. Calculi, including gall-stones, rendered opaque by a crust of lime-salts deposited upon the surface of the cholesterin in the course of years. Many diseases of the lungs and other thoracic organs; diseases of bones and joints; and lastly, a large series of prints showing the progress of an opaque meal through the different parts of the alimentary tract. This last is the province in which the X ray investigation has yielded the most far-reaching results in iding diagnosis. Gastric and duodenal ulcers, ancers of the digestive organs, appendix troubles nd many other abdominal disorders yield their ecrets to the radiological test when all other tests ay have failed to lead to a definite conclusion. he whole study of chronic intestinal stasis epends for the details of diagnosis on the X ray vestigation. This study is fraught with the most r-reaching results to medical science, for it has d to a revision of our views on the ætiology of any of the diseases of the digestive system. Hitherto e have been content to regard "gastric ulcer," duodenal ulcer," "gall-stones," "appendicitis," colitis," &c., as isolated diseases. The teaching of ir Arbuthnot Lane, powerfully supported by the diological investigation, has shown that they are, fact, all parts of one and the same disorder. The ecent important discussion on "diverticulitis" at e Royal Society of Medicine, reported at some ngth in recent issues of THE LANCET, afforded one ore striking instance of the value of radiology in iagnosis. It is interesting to be able to record that ir Arbuthnot Lane[1] published an accurate account f this condition and a true explanation of its athology as long ago as 1886, or fully 11 years efore the earliest description usually recognised.

What are the prospects of radiology during the ext two dozen years? If we look back on the first wo dozen we see that progress, both in apparatus nd in application, has gone on step by step in a niformly progressive manner; so we may assume hat future progress will be steadily maintained, hough we should, perhaps, hardly expect progress be at the same rate now the science of radiology approaching maturity, as during the first years f growth from infancy.

LOCAL EFFECT OF QUININE INJECTION.

QUININE differs from most alkaloids in that it as little or no specific action on any particular ariety of tissue but affects all forms of protoplasm, ausing in small quantities increased activity, in rger doses depression and death. It is this roperty which makes it of such value in the treatment of malaria, for when present in the circulating lood it acts as a direct poison to the delicate rotozoa, especially in their extra-cellular stage. he importance therefore of ensuring a sufficient oncentration of the drug in the circulating blood ecomes obvious, but administration by the mouth oes not always achieve this end, and may, for various easons, be contra-indicated. Of other methods, those ost usually employed are intra-muscular or subcutaneous injections, but neither are altogether ree from objections. The risk of accidental infection may be reduced to a minimum by careful sepsis, but painful swellings tend to form at the ite of inoculation, and necrosis and abscess formation, thrombosis of vessels, nerve palsies, and other omplications have been reported. Reference to our orrespondence columns during the last few months will show that there is no unanimity of opinion as o the best method of administering quinine. Some ractitioners are satisfied with the oral method; thers condemn subcutaneous injections and ecommend intramuscular ones; others, again, ely almost entirely on the subcutaneous method. olonel L. S. Dudgeon, in a recent number of the *ournal of Hygiene*, has investigated experimentally he effect of intramuscular injections of quinine, and has arrived at interesting conclusions. He finds that both concentrated and dilute solutions of quinine produce œdema and muscle necrosis, and though the lesions are more severe with strong solutions they invariably occur unless the drug is in such a weak concentration as to be medicinally useless. In addition to necrosis of muscle there may be destruction of blood-vessels and complete degeneration of nerve trunks. Similar results, however, were obtained by injecting the solvents usually employed without the addition of quinine, and since the author was unable to eliminate their action, the alkaloid cannot be held entirely responsible. In combination with urea, quinine was used at one time to produce infiltration anæsthesia in surgical operations, but troublesome œdema and delayed healing of wounds were such frequent accompaniments that this method of lessening shock has practically been abandoned. Similarly, though it is beyond doubt that absorption is extremely rapid after intramuscular injections of quinine, the severe complications which may attend this practice would seem to contra-indicate it save under exceptional conditions.

THE AFTER-EFFECTS OF GAS POISONING.

THOUGH the earlier effects of gas poisoning have been fully studied, little attention has been paid to the later. Captain S. O. Cowen[1] has described recently the conditions found in 150 Australian soldiers on disembarkation who presented themselves for treatment at the 5th Australian General Hospital since April last. The series included only those considered by the medical boards suitable for treatment as out-patients. Many were gassed at Ypres in the latter part of 1917, and many in the fighting between April and November, 1918. In general they showed the less severe after-effects. There were not sufficient data to make a comparison between the effects of the different gases used, but mustard-gas seemed particularly potent in causing lung lesions. The symptoms were cough, profuse expectoration, dyspnœa on slight effort, sometimes associated with palpitation and præcordial pain, pain in the back, and loss of weight. Physical signs of lung disease were present in 80 per cent. of the cases. In all of these, changes in the percussion note were demonstrable. In the less severe cases there was a small triangular area of impaired resonance in the right interscapular area. In more severe cases this area extended laterally and downwards until it involved the upper portion of the lowest lobe of the right lung. In the most severe cases the dullness in the right interscapular area changed from relative to absolute, and extended slightly across the middle line. In addition there were, in cases of moderate severity, impairment of percussion note at the right apex, and, in the most severe, at the left also. The vocal fremitus was usually increased over the areas of impaired resonance. Auscultation showed over these areas a type of vesicular murmur difficult to classify—broncho-vesicular most nearly described it. There was prolongation of expiration, and the sound was rather hollow and slightly raised in pitch, as though the vesicular element were lessened and the glottic element exaggerated. The vocal resonance was usually increased. Only three cases presented signs of patchy emphysema. In only six were adventitious sounds present—in all fine sibilant rhonchi. The apex beat was frequently displaced 1·25 to 2·2 cm. outwards. The "effort syndrome" was commonly present. Tubercle bacilli were never found in the sputum. Of the prognosis nothing definite can yet be said. The possibility of the supervention of tuberculosis must be borne in mind. Treatment proved unsatisfactory. The return to civil life frequently produced improvement, especially if regular exercise was taken, but exertion was generally avoided by the patient. A series of graduated exercises under supervision is therefore to be advised. In addition to long walks gardening or wood-chopping, slowly increasing the daily amount of work, and open-air life are to be recommended. Drugs seemed of little value. In cases of profuse expectoration a mixture of potassium iodide and creosote seemed to give some relief. These facts show that organic changes are present in the lungs. The most common is peri-bronchial fibrosis, with enlargement of the glands, in the hilum and posterior mediastinum. Why the signs are greatest on the right side is not obvious. Captain Cowen does not agree with the conclusion of a French writer, Achard, that "only a small percentage of the surviving gas casualties will suffer from any permanent disability." In the same number of the journal Lieutenant-Colonel C. E. Dennis, radiographer to the 5th Australian General Hospital, gives his findings in this series of cases. Radioscopy, as a rule, revealed no gross lesion; the apices lighted up evenly, but the whole chest usually showed diminished translucency. Diaphragmatic movement on deep inspiration was always restricted, except on coughing, which showed that the restriction was functional. The hilus shadows were usually more evident than normal, often with patchiness due to glandular enlargement. One condition was so diffuse and faint that it was not at first recognised—an increase in the fibrous tissue of the lungs. This caused diminished translucency, manifested by a thickening and increase in the lines radiating from the hilus. Radiograms confirmed this view.

THE INDICATIONS FOR CÆSAREAN SECTION

THE frequency with which Cæsarean section is being performed calls for consideration. The safety with which nowadays the abdomen can be opened, and the familiarity of many practitioners with this branch of surgery, are likely to cause this relatively easy operation to be performed for a variety of conditions, in which the question as to whether it is or is not the best mode of delivery is a matter upon which there may be differences of opinion. While the student is becoming more and more familiar with the technique of abdominal operations, he is seeing fewer and fewer difficult cases of labour delivered by the vagina. The performance of a simple Cæsarean section calls for less skill and previous training than is required to deliver a patient in a complicated case of labour through the natural passages. We published recently a clinical note by Mr. T. H. Morse on a case of labour obstructed by an ovarian tumour in which, after removing the tumour by the abdomen, he quite rightly and properly proceeded to deliver the patient by the vagina. Unfortunately, the child was born dead, and this fact has led certain of our readers to question the treatment adopted and to suggest that the right thing would have been Cæsarean section to save the child. That mode of delivery was, no doubt, duly considered as an alternative by Mr Morse, who, in our opinion, was right in regarding ovariotomy, followed by delivery per vaginam as the proper treatment. This is the method laid down in text-books, and it has been proved to be the most successful mode of dealing with such cases.

A paper contributed to our columns this week by Mr. Beckwith Whitehouse gives a good summary of the view held with regard to Cæsarean section by some, at any rate, of the younger obstetricians. The decision as to the advisability of this operation largely turns upon the relative value placed upon the life of the mother as compared with that of the life of the child. Mr. Whitehouse, in contrasting the results obtained by the induction of premature labour with those following Cæsarean section, states that the maternal mortality following the induction of premature labour is nil, while the fœtal mortality, as calculated by Eden, is some 13 per cent.; from these figures he argues that we are justified in risking a possible maternal mortality of some 3 per cent. for the sake of lowering this fœtal mortality of 13 per cent. But are we? Which are the more valuable to the community as a whole: three mothers, perhaps in the prime of life and still in the child-bearing period, or a possible ten new-born children? As Mr. Whitehouse points out in his interesting paper, the proper treatment for any case of obstructed labour is its prevention and the recognition of the condition which is likely to lead to the obstruction. Every case of obstructed labour recognised for the first time late in labour is an indication that someone has blundered. We believe that however abhorrent it may be to craniotomise a living child, yet in a few of these cases it must and should be done. Mr. Whitehouse's estimate of a maternal mortality of 8 per cent. for craniotomy makes no distinction between craniotomy on the dead child, which has a mortality of rather less, in our opinion, than the figure he quotes, and craniotomy on the living child, which has a very much lower mortality, only some 1–2 per cent., and which alone is comparable to that of Cæsarean section. The reason for this is, of course, that in the one case the woman is often in extremis before the operation is performed, whereas when the necessity for it is recognised, before futile and prolonged attempts have been made to deliver, the risk is much less.

Cæsarean section is now being performed with considerable frequency for placenta prævia. There are many conditions threatening the life of the child in this complication of labour besides that consequent on podalic version, whether bipolar or internal. If Cæsarean section is to be performed for placenta prævia the cases must be carefully chosen. The fact that only one-third of them go to full term, and the grave risk from the abnormal position of the placenta to the life of the child, must be borne in mind, while in any large number of cases it is very unlikely that the maternal mortality will be as low as that after Cæsarean section, when performed as an operation of election for a contracted pelvis. The question as to whether Cæsarean section should become the routine treatment for cases of eclampsia is one even more difficult to answer. It is not easy to believe that the excellent results obtained by the Rotunda method would have been better still if all the patients had been delivered by abdominal section. One of the greatest authorities in this or any other country on renal disease has given his opinion that the performance of Cæsarean section for eclampsia is but a clumsy method of bleeding the patient! No doubt an exaggeration, but possibly one in which there is more than an inkling of truth. The risk of rupture of the scar of a Cæsarean section in a subsequent pregnancy must, in conclusion, be remembered. Most obstetricians who have delivered a patient by this method feel that in any subsequent pregnancy it must be performed again.

THE INTERNATIONAL SOCIETY OF SURGERY.

THE triennial meeting of this society will be held at Paris instead of Brussels this year, from Monday, July 19th, to Friday, July 23rd. The subscription is 50 francs. Members of the medical profession who wish to be nominated for election are requested to communicate with Sir D'Arcy Power, K.B.E., 10A, Chandos-street, Cavendish-square, W. 1. The subjects set for discussion are: (1) The surgery of the heart and great vessels; (2) the treatment of tumours by radium and X rays; (3) the analysis of the blood and its biological reactions in surgical affections; (4) fractures of the femur; (5) the prophylaxis and treatment of tetanus.

THE USE OF CONCEPTS IN MEDICINE.

IN an address on First Principles delivered before the Section of Epidemiology and State Medicine of the Royal Society of Medicine on Jan. 23rd Dr. F. G. Crookshank reproached physicians of the present day, and even epidemiologists, with their content to avoid discussion of first principles and of general notions, holding, with John Hunter, that definitions are, of all things, most damnable. Under the influence of certain schools of thought and certain habits in expression we have become accustomed to speak and write as if a disease were a natural object, permitting physical recognition by those whose business it is to be familiar with diseases of various kinds—in the manner of schoolboys who "spot" a butterfly or a postage stamp. But, Dr. Crookshank goes on—

> ...... the clinical physician varies from day to day the content of his disease-concepts, in accordance with a posteriori results and the dictates of academic convenience: not only in respect of the causes but, as his knowledge accrues, and his point of view changes, in respect of the symptoms described. He makes cross references, and mentally files his observations sometimes one way, sometimes another. So inevitably, what is but a symptom-group to-day may become a "disease" to-morrow: what now appears a disease may, next week, be considered but a part of a greater construct.

The word "epidemic" has, Dr. Crookshank finds, also been used in several senses, of which one is adjectival and obvious, and the others substantive, and this plurality of usage has tended greatly to obscure thought, to the present ascendancy of positivism in epidemiology. We speak of "epidemic disease," meaning thereby disease which we conceive as tending to become prevalent; and we speak of special epidemic diseases, referring thereby to special disease-concepts which embrace the notion of a tendency to prevalence or diffusion. The expressions "disease," "epidemic," and "epidemic constitution" are, in fact, used with reference to correlated symptoms in individuals, cases in communities, and cases and prevalences amongst populations during determinate periods. Each of these usages is legitimate so long as it is understood, but error and confusion are inevitable when specific concepts are regarded as having objective existence. Dr. Crookshank holds that a belief in the objective existence of ideal diseases, epidemics, and epidemic constitutions obscures the value of these mental constructs, the real use of which is as schemata for the prosecution of profitable a posteriori research.

A DIPLOMA IN TUBERCULOSIS.

THE occasion of the gathering of distinguished medical men and laymen interested in the treatment of surgical tuberculosis at a complimentary luncheon in his honour was utilised by Sir Henry Gauvain to press for the establishment of a special diploma in tuberculosis. The Treloar Hospital at Alton, with which his work has been identified, affords unrivalled opportunities for the study of the local manifestations of tuberculosis in childhood, and for some time past intensive post-graduate courses have been held there. It is probably impossible to obtain anywhere such a bird's-eye view of adult tuberculosis, but the Brompton Hospital for Consumption is arranging lectures and demonstrations, of which details may be seen in our advertisement columns. Outside London and Edinburgh little use is made of the abundant teaching material in our tuberculosis institutions. The Trudeau School at Saranac Lake is a reminder of what might be done with great advantage in this country. With the resolution of the Tuberculosis Society to make representations to the various examining bodies on the need for stimulating a systematic study of tuberculosis we have every sympathy.

THE NEW HOSPITAL UNITS.

THE university status of metropolitan medical schools is being completed by the establishment of medical and surgical units which are destined to play a large part in the development of medical education in London. The appointments at St. Bartholomew's and St. Thomas's have already been announced. Since the beginning of the New Year medical and surgical units have been in full working order at University College Hospital. As will be seen in our news columns, this hospital has not hesitated to go outside its own staff, and has appointed, as first assistant to Dr. T. R. Elliott, Dr. J. W. McNee, of Glasgow, and as director of the surgical unit Mr. C. C. Choyce, surgeon to the Great Northern Central Hospital and lately dean of the London School of Tropical Medicine. The University College Hospital School of Medicine is fortunate in possessing ample facilities for pathological research by the directors and their assistants in the laboratories endowed by the wise forethought of the late Professor Charles Graham. In all these hospital units three-fourths of the total approved cost is to be paid by the Board of Education, the remainder being found by the medical school itself. At University College both directors and assistants are debarred from private practice; at St. Bartholomew's first and second assistants are designedly left some free time for outside work; and it will be of interest to see which system proves the more advantageous. While the freedom of the directors from competing interests is an important part of the new organisation, we cannot overlook the great importance to the students of receiving some of their clinical instruction from teachers in close touch with more highly educated patients than constitute at present the in-patient material of general hospitals. This clinical instruction will be given in the future, as it always has been in the past, by the remaining members of the hospital staffs, who will continue to devote their time to clinical and bedside teaching, and who will be able to do this with enhanced energy when relieved from the task of systematic teaching.

THE ADMINISTRATION OF THE SALE OF FOOD AND DRUGS ACTS THROUGH THE WAR.

THE routine work of our authorities responsible for the administration of the Sale of Food and Drugs Acts must through the war have been much disturbed by the system of control over alcoholic beverages, foods, and drugs which was forced upon the Government by the crisis. Judging from a circular issued by the Ministry of Health last week to the officials of the counties and boroughs concerned, there is evidently a movement forward to bring the administration of these Acts into old lines again. In this circular attention is directed to the powers and duties of local authorities under the Sale of Food and Drugs Acts, and a tacit admission is made that in many areas the exercise of these powers and duties was unavoidably curtailed to some extent during the war owing to the shortage of staff and the pressure of special work. The Ministry attach great importance to the effective administration of these Acts, and express the hope that local authorities will take all possible steps to ensure that the powers conferred upon them are fully utilised. We feel sure that this is no reflection on the admirable work of public analysts during anxious and trying times. No public servant has found it harder to keep his public services going throughout this period, since most of them liberated their assistants, who were qualified chemists, to place their technical knowledge at the service of munition making, sanitary work in the field, and the defensive methods set up against the attacks of poison gas. In the meantime cases of food poisoning or of proved fraud were remarkably rare in spite of the great struggle at times to get food products at all. The public owe much to our food controllers—and in this term we include the medical officers and public analysts.

THE DEATH OF MR. CECIL R. C. LYSTER.
